The Whole entirely freed from the Errors, Obſcurities, and Superfluities of former Writers on the various Subjects; and forming a more METHODICAL, INTELLIGENT, and COMPLETE REPOSITORY of

UNIVERSAL KNOWLEDGE,

Than any other WORK, of a ſimilar Nature, ever publiſhed in the ENGLISH LANGUAGE.

Illuſtrated with upwards of 150 Large Superb COPPER PLATES, *accurately* Deſcriptive of the Subjects to which they refer.

IN THREE VOLUMES.

VOL. I.

NON SIBI, SED PATRIÆ. CATO.

k By WILLIAM HENRY HALL, ESQ. *Millman Place, Bedford Row, London.*

ASSISTED BY OTHER LEARNED AND INGENIOUS GENTLEMEN.

LONDON: PRINTED FOR C. COOKE, No. 17, PATER-NOSTER ROW.

BRITISH MUSEUM

Abſtract of the Genuine Copy of His Majeſty's Royal Privilege and Licence, granted under his own Hand and Seal, at St. James's, for the ſole Printing of this Work.

GEORGE R.

GEORGE the Third, by the Grace of God, King of Great Britain, France, and Ireland, Defender of the Faith, &c. To all to whom theſe Preſents ſhall come Greeting. Whereas CHARLES COOKE, of Pater-noſter Row, London, Bookſeller, hath, by his Petition, humbly repreſented unto Us, that he hath been at a very great Labour and Expence in employing WILLIAM HENRY HALL, Eſq. of Millman-Place, Bedford-Row, London, with other learned and ingenious Gentlemen, to write and compile a Work, entitled, "The NEW ROYAL ENCYCLOPÆDIA; or, "Complete Modern DICTIONARY of ARTS and SCIENCES. Containing a New, "Univerſal, Accurate, and Copious Diſplay of the Whole Theory and Practice "of the Liberal and Mechanical Arts, and all the reſpective Sciences, human and "divine, arranged ſyſtematically, and digeſted into diſtinct Treatiſes. Alſo the various "detached Parts of Knowledge, copiouſly and critically explained, according to the "beſt Authorities. Comprizing a regular and general Courſe of Ancient and Modern "Literature, from the earlieſt Ages down to the preſent Times; including all the "lateſt Diſcoveries and Improvements in the various Branches of Literature. The "Whole entirely freed from the Errors, Obſcurities and Superfluities of former "Writers on the various Subjects; and forming a more Methodical, Intelligent and "Complete Repoſitory of ARTS and SCIENCES, than any other Work of a ſimilar "Nature, ever publiſhed in the Engliſh Language. Illuſtrated with upwards of 150 "large ſuperb Copper Plates, beautifully Deſcriptive of the ſeveral Subjects to which "they refer."

We being willing to give all due Encouragement to this Undertaking, are graciouſly pleaſed to condeſcend to the Petitioner's Requeſt. And we do therefore, by theſe Preſents, grant unto him the ſaid CHARLES COOKE, his Heirs, Executors, and Aſſigns, Our Royal Licence and Authority, for the ſole printing, publiſhing and vending the ſaid Work, for the Term of Fourteen Years. Given at our Court at *St. James's*, this 13th Day of *Auguſt*, 1788.

By His Majeſty's Command, SYDNEY.

ADDRESS TO THE PUBLIC.

A Knowledge of the various branches of Art and Science has ever been conſidered the greateſt acquiſition that can adorn, ornament, and dignify human nature: the ſtudy of them naturally enlarges the mental faculties, poliſhes the behaviour of mankind, and introduces an happy correſpondence between the ſeveral members which compoſe extended ſociety.

It is preſumed that little apology need be made for the publication of ſuch a Work at this time, notwithſtanding there have been others of a ſimilar nature uſhered into the world. The great and glaring defects in theſe productions have been too conſpicuous to paſs unnoticed, as all abound in erroneous principles, whether ſimply, in detached parts; or complexedly, in ſyſtems. To point out theſe defects would be endleſs, as we mean not to ſeek for reputation from the imbecility of others.

In order to avoid theſe imperfections, it ſhall be our invariable plan, through the whole courſe of the work, to draw our deſcriptions clear and intelligent, without ſcholaſtic pedantry, unintereſting prolixity, or unmeaning brevity; at the ſame time to retain every technical term applied to the various branches of Art and Science, in their detached parts: the ſyſtematical order of acquired knowledge regularly arranged, juſtly diſplayed, critically defined, and illuſtrated according to its real principles, ſtrictly adhering through the whole, to purity and elegance of diction.

The plan of the New Royal Encyclopædia is founded on ſuch principles as to bring the Advancement of Science to its ultimate perfection, by a critical diſcrimination in expunging obſolete hypotheſes and uſeleſs theories, and adapting only thoſe that are truly valuable, of which proofs have been obtained under their various denominations. The method we have alſo adapted of treating of the different kingdoms of nature, and the true ſcientific diſcrimination of their component parts, muſt neceſſarily render it not only a work of ſuperior merit, but of unrivalled reputation in the annals of literature.

⁂ *The Proprietors of the* NEW ROYAL ENCYCLOPÆDIA, *even in this early Stage of the Work, have expended upwards of* ONE THOUSAND POUNDS *in the Purchaſe of* New Publications, *in all the* different Languages, *conſequently* Novelty *and* Utility *will abound throughout every Page, diſdaining to offer to the Public ſuch Chaotic Compilations as have hitherto appeared founded in* Error *and* wrong *Conſtruction.*

ADVANTAGES attending this NEW PUBLICATION.

I. Inſtead of the cuſtomary plan of giving only *one* copper-plate in every *fourth* number; in this work will be delivered one or more *gratis*, with *every* number.

II. The purchaſe of this work, will be near *ten guineas* cheaper than any other Cyclopædia, or Encyclopædia, and the time of compleating it conſiderably leſs.

III. That the page being made much *larger* than that of the Cyclopædia, each number will contain a greater quantity of letter preſs.

IV. In this work all the *new* improvements and *important* diſcoveries that have taken place down to the preſent æra, not only in this kingdom, but in every poliſhed nation in the known world, will be ſtrictly preſerved, whereby the arts will be brought to a criterion of perfection unknown in former ages.

V. The plates are engraved from original deſigns, drawn on purpoſe for this work, by the moſt ingenious artiſts; and will be found, on examination, to ſurpaſs every other publication extant, as the ſubjects will be more *numerous* and *accurately* delineated.

VI. The whole work will be printed on fine paper, elegant type, with uniformity, accuracy and preciſion; and in order to preſerve an *invariable beauty of printing* throughout the whole, *each volume* will begin with an *entire new letter*, ſo that the work cannot contraſt a *worn appearance*, as is really the caſe with other publications.

18 MR 63

Animated with a laudable deſire of making myſelf uſeful to the public, I have, in this arduous undertaking, dedicated my whole time for ſeveral years paſt to the ſtudy and improvement of the various branches of the Arts *and* Sciences; *and flatter myſelf that the great pains I have taken in compoſing and completing the Work (on which I build my literary reputation) will meet with a candid reception from the public.*

Millman Place, Bedford Row, Auguſt 26, 1788. *W. H. HALL.*

TO THE

KING.

SIR,

PERMIT me to lay before your *Majeſty* thoſe Labours and Efforts, which have been exerted to diſplay the advanced State of the Arts and Sciences to which they have attained under your *Majeſty's* Influence and Encouragement from the Commencement, to the preſent Period of your *Majeſty's* auſpicious Reign.

There is a Time reſerved in the Fate of every Nation to arrive at its Perfection, and the riſing Genius of Britain bears a promiſing Aſpect of attaining, under your *Majeſty's* Protection, to the Summit of Excellence in the Purſuits of *Philoſophy* and *Literature.*

There certainly cannot be any literary Production better calculated for diſſeminating and promoting Univerſal Knowledge, or that deſerves more the Countenance and Protection of the Great, than a Work which comprehends the whole Circle of Arts and Sciences: and it is for this Reaſon, as well as your *Majeſty's* known Patronage, and thorough Knowledge of the Polite Arts, that the Editor is emboldened to lay this Work at your *Majeſty's* Feet; eſpecially, as Productions which tend to enlarge the Boundaries of Science have a peculiar Claim to the Countenance and Protection of *Monarchs*; for, by the Diffuſion of Science, Man is civilized, the Inlets to Happineſs are opened, and Society is formed on a firm, advantageous, and ſolid Baſis.

The elegant Enjoyments of Life are heightened in Proportion to our Knowledge of thoſe Sciences, which owe their Birth to an Acquaintance with the Powers of Nature and Art, without which, Rank and Fortune would be of little value. It is the Source of Happineſs, as it extends the Views and enlarges the Comprehenſion of the Human Mind, by which means the Dignity of our Nature is ſupported, and the beſt Foundation laid for the Advancement of intellectual Happineſs.

In the Scientific Departments of this Work, the Attention of the Reader is directed to thoſe Laws of Divine Order by which the Univerſe

verſe is governed and ſupported. In the Survey of Animated Nature, we ſee that the Protection of the great Creator is extended to the minuteſt Parts of his Creation; Beings, infinitely ſmall, manifeſting to the aſtoniſhed Eye, the ſame Proportion, Regularity, and Deſign as thoſe of the firſt Magnitude; all of which enjoy their reſpective Comforts, and triumph in the Bounty of the Sovereign of the Univerſe.

The Mind, from a Review of the Beauty and Order in which all things are formed, and the ſeveral Uſes to which they are appropriated, is led to contemplate the wonderful Effects of Divine Omnipotence, and adore the benificent Creator in all his Works, which proceed from Wiſdom, and originate in Love.

As the Arts and Sciences are at this Period ſo generally cultivated, and ſo liberally encouraged, thoſe who labour to advance them, even in the humble Department of collecting and arranging the Diſcoveries of others, eſſentially conduce to facilitate their Attainment, and, by ſhewing what is already obtained, excite Emulation, and quicken Invention.

I have ſelected impartially the Communications of the learned and ingenious of every Nation; but feel a peculiar Pleaſure in ſtating thoſe modern Inventions, Diſcoveries, and Improvements which do equal Honour to my native Country, and the diſtinguiſhed Liberality and Munificence of its Sovereign.

Theſe Diſcoveries and Improvements in the Arts and Sciences, which owe their Progreſs ſo materially to the Protection of your *Majeſty*, muſt be productive of the moſt happy Tendency; and the Knowledge they communicate muſt diffuſe that permanent Glory which cannot be obtained either by Conqueſt or Dominion.

That your *Majeſty* may long enjoy the exalted Satisfaction of promoting the Arts and Sciences, ſo worthy of your Royal Protection, is the ſincere Wiſh of

Your *Majeſty's* moſt dutiful,
And obedient Subject,
And Servant,
W. H. HALL.

18 MR 63

PREFACE.

IT is certain that no compoſition whatever can tend ſo effectually to the advancement of *general* knowledge, as that of a Dictionary of Arts and Sciences, wherein every article, of which the whole ſyſtem of nature conſiſts, is depicted in all its beautiful colours.

In eſtimating the importance and utility of a Scientific Dictionary, it is a mattter of no ſmall conſideration, that it ſupplies, in a great meaſure, the want of a large library, by furniſhing the inquiſitive and curious with hints and abſtracts of ſcience, that are diſperſed in many volumes, which cannot be procured without difficulty, and without conſiderable expence. Such a work, therefore, muſt appear of very high importance, the eſtimation of which ariſes from the knowledge purſued and promoted throughout its progreſs.

A work of this kind, from its extent and arrangement, is ſuited to the occaſions, and to the convenience of many perſons, who have neither leiſure or opportunity to recur to thoſe different ſources of information, whence the materials of which it is compiled are collected. To others, whoſe acquaintance with particular branches of ſcience, precludes the neceſſity of their application to ſuch a work, it will communicate general information concerning ſubjects, to which their attention has not been ſo immediately directed; and thus afford them leiſure for gratifying their taſte, or inclination, in reſearches, which they may deem more important or more pleaſing; and in which they may be more ambitious of excelling. It muſt likewiſe be remembered, that this Dictionary records and tranſmits to future ages, many inventions and improvements, which might otherwiſe have ſunk into oblivion; that it forms a compendious hiſtory of ſcience; that it furniſhes the outlines of its gradual progreſs and advancement; and that, by preſerving a ſummary of what has been already done and diſcovered, it lays a farther foundation for more extenſive diſcoveries and improvements. In this latter view of its importance and uſe, it may not be improperly compared to a map of ſcience, in which the line that terminates the *terra cognita* is diſtinctly marked out, for the direction of thoſe, whoſe ingenuity and induſtry are employed in extending the circle of knowledge, and in exploring thoſe regions that are ſtill unknown.

It is admirably adapted to the nature and neceſſary limits of a popular work; deſigned not merely for public libraries, and for the uſe of thoſe who ſpare no expence in obtaining the beſt means of information, but for diſſeminating literature and ſcience through the ſubordinate claſſes of mankind. With this view we have adopted the happy medium between a work conſiſting merely of definitions, etymologies, and references, and a voluminous collection of diffuſe and elaborate treatiſes on various ſubjects, the price of which muſt reſtrict it to few purchaſers, and the peruſal of which would be thought tedious by many, who had occaſion for conſulting it.

The deviation made from the plan of Chambers, and others, by introducing detached Syſtems on the Sciences, Treatiſes on the Arts, and Diſſertations on Philoſophical Subjects, it is hoped will meet with the approbation of the Readers: and, in order to exhibit theſe important branches of knowledge in their full extent and luſtre, we have re-united all the detached parts, that their proportions, their relations one to another, and to the general Syſtem, of which they are conſtituents, might be more clearly and obviouſly perceived. This method has been purſued throughout the courſe of the work; and it is certain, that ſuch a plan, regularly and ſucceſsfully proſecuted, muſt be productive of numberleſs utilities and advantages. But when ſubjects, inſtead of being digeſted into Syſtems, or diſpoſed in their natural order, are dilacerated, diſſected, and diſſeminated, without regard to connection, or ſyſtematic combination, merely as the ſucceſſion of the letters, which conſtitute their technical terms, determine, without mentioning their antecedents, and conſequences, ſuch a work ſhould rather be called a collection of Miſcellanies than a *Dictionary of Arts* and *Sciences:* works executed upon this plan cannot have a due influence on the mind, and an underſtanding, formed upon ſuch models, is rather a chaos of detached and heterogeneous ideas, than a regular intellect.

It is only by thinking in method, by reducing our ideas to a proper and rational order, by obſerving what they poſſeſs in common, and what are their relations or differences, that our reaſoning faculties are capable of making any progreſs at all. Without theſe aſſiſtances, we might be ranked amidſt ſenſitive, or conſcious beings, but could never attain to the human or rational character.

Leſt any objection ſhould be ſuggeſted in the mind of the Reader to Syſtems and Treatiſes, from an idea of the neceſſity of peruſing a whole Syſtem for information, concerning a particular part only, the Editors, to obviate this objection, have been attentive in the alphabetical department of the Dictionary, to give a compendious, yet clear account of the ſeveral detached parts, which refer for further information to the Syſtem to which they appertain. Detached articles may be divided into three kinds. The firſt conſiſts of ſuch as, independent of particular Syſtems, admit of a full and complete illuſtration as they ſtand; the ſecond, of ſuch as require partly to be diſcuſſed under the Syſtems to which they belong, and partly under their own proper denominations; the third, of ſuch as are ſufficiently elucidated in the Syſtems to which they appertain. Thoſe of the firſt kind need no references. Thoſe of the ſecond, being only partially explained under their particular denominations, demand references to the Syſtems where the illuſtrations are completed. For thoſe of the laſt, as no explication is found neceſſary under the terms, we refer to the Syſtems of which they are conſtituents, where the ſubjects are fully diſcuſſed. Theſe our readers may conſult as emergencies require, or their own diſpoſitions impel them.

Thus the Syſtematic Reader will be fully and regularly informed, by referring to the general name of the ſcience he wiſhes to explore; and the proficient who wiſhes to refreſh and ſtrengthen his memory in any particular part, may find the ſame by turning to the Alphabet, which, having general references, ſerves as an index to the Syſtems and Treatiſes, whilſt others, who are willing to content themſelves with partial and detached views of ſubjects, will find them explained under the articles, by which they are denominated, as by a courſe of references, form particulars to generals, from premiſes to concluſions, from cauſe to effect, and *vice verſa*; i. e. from more to leſs complex, and from leſs to more: a communication is thereby opened between the ſeveral parts of the work. Thus the Syſtem is rendered an improvement of the Dictionary, and the Dictionary an advantage to the Syſtem, which is the only method, by which the whole circle, or body of knowledge, with all its parts and dependencies, can be fully diſplayed.

The great utility of detached Syſtems and Treatiſes will obviouſly appear from the following particular inſtances; in which may be ſeen, how abortive and impotent the attempts of the Compilers of Dictionaries have proved, who have endeavoured, by their references, to direct their readers to form Syſtems and Treatiſes from the detached and ſcattered parts of the Alphabet; as for inſtance; in Chambers's Dictionary, in the Preface of which, adverting to the plan of the work, he mentions amongſt an enumeration of articles; *Agriculture*, to obtain a compleat knowledge of which all the component parts are ſeparately to be referred to; as *Tillage* and improvement of *Soils*, *Clay*, *Sand*, *Earth*, &c. by the operations of *Ploughing*, *Fallowing*, *Burning*, *Sembradore*, *Semination*, *Manuring*, &c. to produce *Corn*, *Hemp*, *Flax*, *Liquorice*, *Saffron*, &c. for *Malt*, *Farina*, &c. *Granary*, *Threſhing*, &c. The culture of *Trees*, *Timber*, &c. by *Planting*, *Shrowding*, *Barking*, &c. for *Coppice*, *Park*, *Paddock*, *Hedge*, *Paſture*, &c.

But how extremely difficult it would be to follow a ſubject through ſuch a multitude of references, as well as new ones which ſpring up at every one of them, any perſon may eaſily conceive. From theſe obſervations, we hope that our Plan in the introduction of Syſtems and Treatiſes will be allowed to be good, whatever exceptions may be taken to the execution of it.

We have endeavoured to give the ſubſtance of every thing that has been hitherto diſcovered in the ſeveral branches of knowledge, both natural and artificial; that is, in the knowledge of *nature*, firſt, as ſhe appears to our ſenſes, either ſpontaneouſly, as in *Natural Hiſtory*; or with the aſſiſtance of art, as in *Anatomy*, *Chemiſtry*, *Medicine*, *Agriculture*, &c. ſecondly, to our imagination, as in *Grammar*, *Rhetoric*, *Poetry*, &c. thirdly, to our reaſon, as in *Phyſics*, *Metaphyſics*, *Logics* and *Mathematics*: with the ſeveral ſubordinate arts ariſing from each, as *Agriculture*, *Painting*, *Sculpture*, *Trade*, *Manufactures*, *Policy*, *Law*, &c. and numerous remote particulars, not immediately reducible to any of theſe heads; as *Heraldry*, *Philology*, *Antiquities*, *Cuſtoms*, &c. To accompliſh a taſk ſo arduous and important, neither labour nor expence has been ſpared. Every reſearch has been made; particular ſciences have been collected and compared. Such as could be abridged without diſadvantage, have been epitomized with all poſſible care; while others, who were more conciſe and tenacious in their ſubjects, have been more cloſely purſued, and more faithfully retained. When topics have been obſcurely or imperfectly treated, the utmoſt endeavours have been uſed to ſupply theſe defects; and upon ſuch parts of ſcience as the compilers have not found properly illuſtrated by other authors, original eſſays are inſerted.

We have not been content with taking what was already collected, but have augmented our work with a large acceſſion from other quarters. Few parts of the commonwealth of learning but have been applied to on this occaſion. Recourſe has been frequently had to the originals themſelves on the ſeveral arts; and not to mention what ſmall matters could be furniſhed from our own ſtock, the reader will here find extracts and accounts from a great number of books of all kinds, either overlooked by former lexicographers, or not then extant; and a multitude of improvements in the ſeveral parts, eſpecially of natural knowlege, handed down to the lateſt period.

After embarking in ſo great an undertaking, we were determined to perſevere with unremitting attention, and to make every effort, of which we were capable, for improving the work, and ſecuring the approbation of our readers. With an induſtry and ardour, which the hope of giving ſatisfaction to the public animated, and which the extent and importance of the undertaking both deſerved and required, we have devoted to the accompliſhment of it all that time and attention, in the courſe of many years, which our other engagements would permit; and we think ourſelves happy, that no accident has prevented the progreſs of a publication, to the completion, as well as the reputation and ſucceſs of which, our wiſhes and labours have been uniformly directed.

We reflect with pleaſure, and with grateful reſpect to the numerous purchaſers of this new Work, that our labours, in the cauſe of ſcience, have been ſo favourably received. We truſt, that we may be allowed to interpret the extenſive ſale, with which it has been honoured, as a teſtimony of the approbation, as it is a full proof of the candour, of the public. Acknowledging that candour, and confiding in it, it is needleſs to urge thoſe apologies, which are furniſhed by the magnitude of this publication, and the variety of ſubjects it comprehends; but we ſhould have been unworthy of the indulgence we have experienced, and to which we farther appeal, if we had not conſidered it as an encouragement to unremitting application.

The Editors gratefully acknowledge the hints and communications, which they have received, both in converſation and writing, for the improvement of the work; and think themſelves under peculiar obligations to the friendſhip of thoſe gentlemen, who have formed Syſtems and Treatiſes on various ſubjects, according to their reſpective abilities, and to which, as a teſtimony of their being original, they have affixed their ſignatures.

Several flattering teſtimonies of approbation, from unknown correſpondents, demand alſo the reſpectful acknowledgements of the Editors; as they have contributed to animate their aſſiduity and perſeverance, in the proſecution of an undertaking, which required reſolution, patience, and every effort that could combine to eſtabliſh their reputation as compilers; and gratify the wiſhes and expectations of the public.

It is very natural to ſuppoſe, that a work of ſuch magnitude as this, and containing ſuch a variety of articles, muſt be ſubject to errors, though every poſſible means have been uſed to avail ourſelves of ſuch defect. But the moſt careful cannot elude human fallibility. Accidents of this kind will not appear ſurpriſing, when we conſider, in what a variety of ways man is open to error. Perhaps an author, on whom we depend, deceives us; our own judgment betrays us; our attention leaves us for a moment; or, ſuppoſe we eſcape all theſe ſnares, we may be brought into a ſcrape by an amanuenſis; or, if we get clear here too, we are in imminent danger of miſcarrying in the hands of the printer. In ſhort, the moſt we can ſay is, that we hope there will be but few errors found in this work, in compariſon with others of the like kind. Many thouſands we have corrected, both in the Dictionaries and other writings, from whence we have collected, and this by means of the light, which other parts of knowledge afforded. We therefore, flatter ourſelves, that what we have overlooked, the reader will frequently be enabled to correct; and that there will not be many errors found in the book, which the book itſelf will not help to rectify.

In a collection ſo large and multifarious, as that which is now recommended to the public attention, the critic muſt be ſevere, and the genius minute, who could ſtop to animadvert upon every trivial inaccuracy of ſtyle. We think it indeed indiſpenſibly incumbent on every author who would be read with intelligence and pleaſure, after ſufficiently attending to the nature and importance of what he ſubmits to the public obſervation, that he ſhould, in the next degree, regard the vehicle by which it is conveyed. But where the ſubjects are ſo indefinitely varied, and where propriety requires that each ſhould be expreſſed in a manner ſuitable to its nature, it can ſcarcely be imagined, that the ſame exactneſs and uniformity ſhould equally prevail in this as in compoſitions of a nature leſs extenſive and complex.

After all, though the compilers are conſcious of having done their utmoſt to render this work as extenſively and generally uſeful as it could poſſibly be; yet, ſince no human production, even from the origin of literature to the preſent period, has ever been found perfect in its kind, it would be cruel, if not unjuſt, to expect abſolute perfection in the preſent attempt. From every candid and benevolent inquirer after truth, therefore, they hope, that the merit of their intention and the utility of their plan will in a great meaſure atone for ſuch trivial or unavoidable faults as may be found in its execution. When the nature of a work ſo extenſive and multiform is duly conſidered, it will immediately occur to every reader of candour and indulgence, how eaſy it is for the utmoſt care and aſſiduity to fail in ſome inſtances. Theſe, however, it is hoped, will be found few and of little imporance; the work, during its whole progreſs, having been ſuperintended with unremitting vigilance and aſſiduity.

18 MR 65

THE NEW ROYAL
ENCYCLOPÆDIA;
OR, COMPLETE MODERN
DICTIONARY
OF
ARTS and SCIENCES.

A

A, The firſt letter of the alphabet in all the known languages of the world, except the Ethiopian tongue, of which it is the thirteenth letter. The Hebrews call it *aleph*, the Greeks *alpha*, the Syrians *oleph*, the Arabians *eleph*, and all the modern living languages of Europe call it *aw*, the Engliſh nation excepted, who called it *ày*. Its ſimplicity of ſound has deſervedly given it the firſt place in the alphabet, very little more being neceſſary to its pronunciation than opening the mouth pretty wide and emitting the air from the lungs.

This character in the Engliſh language is marked with three different ſounds, viz. 1, open, as in *war*, *talk*; 2, cloſe, as in *wake*, *take*; 3, broad, or wide, as in *hall*, *wall*. Note, the cloſe ſound is frequently called the ſlender A.

The ſlender or cloſe A, is peculiar to the Engliſh language, and reſembles the ſound of the French *e*, maſculine, which ſound it invariably retains in the termination of words that are purely Engliſh. Herries, Holder, and Wallis, have, with great ingenuity and philoſophical nicety, treated of the various ſounds of this leading letter in their learned Treatiſes on the ſounds in our language.

Mr. Sheridan's ſcheme of the ſounds is too complex to be of real utility. As to the performances of others, they are too trivial to be critically examined.

To treat minutely on the variety of ſounds in which this letter occurs, would be incompatible with our plan, as it would run into an unintereſting prolixity that could anſwer no intention whatever.

A is always a vowel, and frequently ſtands for a word in the Engliſh language, which grammarians call an *article*. See Syſtem of GRAMMAR.

A, is alſo a name in aſtronomical calculations, being uſed as a character to ſignify the firſt Dominical letter; the Julian calendar containing ſeven. It had been in uſe among the Romans long before the Chriſtian æra, as the firſt of the eight *nundinales litteræ*, nundinal letters, in imitation whereof the Dominical letters were firſt introduced. See Syſtem of ASTRONOMY.

A, is in abbreviature uſed with different intentions; viz. in logic, A denotes an univerſal affirmative propoſition, according to the verſe——

Aſſerit A, *negat* E, *verum generaliter ambæ.*

Thus in the firſt figure, a ſyllogiſm, conſiſting of three univerſal affirmative propoſitions, is ſaid to be in Bār-bā-rā; the A, thrice repeated, denoting the number of the propoſitions to be univerſal.

In commerce, A, ſignifies *accepted*, when prefixed to the name of an acceptant on a bill of exchange. It is alſo uſed as a numeral letter to expreſs the number of the counting-houſe books; for inſtead of marking the waſte-book, journal, or ledger, with 1, 2, 3, &c. the letters A, B, C, &c. are always ſubſtituted.

In hiſtory, and other records, ancient and modern, the letter A is uſed with various intention.

In the Roman ſenate, A was uſed in the giving of votes or ſuffrages. When a new law was propoſed, each voter had two wooden ballots put in his hand, the one marked with a capital A, ſignifying *antiquo*; q. d. *antiquam volo*; and the other with V. R. for *uti rogas*. Such as were againſt the law, caſt the firſt into the urn, as who ſhould ſay, I refuſe it, I antiquate it, or I like the ancient law, and deſire no innovation.

In criminal cauſes that came before them for trial, A, denoted *abſolution*; whence Cicero, *pro Milone*, calls it *littera ſalutaris*, the ſaving letter. Then three ballots were diſtributed to each judge, marked with the letter A, for *abſolvo*, I acquit; C, for *condemno*, I condemn; and N. L. for *non liquet*, it is not clear: from the number of each caſt into the urn the prætor pronounced the fate of the priſoner: But if the ſuffrages for condemning and acquitting were equal, then the accuſed perſon was always ſet at liberty.

In inſcriptions on medals, ancient and modern, A ſignifies *Auguſtus*, *ager*, *aiunt*, *ante*, *ære*, *ædes*, *aula*, *anima*, *amicus*, *amica*, *alba*, *acta*, *alia*, *&c.* when double, AA, ſignifies *Auguſti*, and triple, AAA, ſtands for *auro*, *argento ære*; or *aurum*, *argentum*, *æs*; and ſometimes it is underſtood, according to Iſidore, when it occurs after *miles*, ſoldier, to denote him young. On the Greek and Roman medals, the letter A denotes the name of the place where they were ſtruck, as Athens, Argos, Antioch, Aquileia. On modern coins, a ſingle A is the mark of Paris, and a double AA, that of Metz.

In modern arts, A carries a further ſignification. Thus, A. B. ſignify, *Artium Baccalaureus*, Batchelor of Arts; A. M. *Artium Magiſter*, Maſter of Arts; A. B. ſometimes ſtands for *alia bona*, A. C. for *acta cauſa*, A. D. *Anno Domini*, &c.

The Romans in their writings dated all matters of buſineſs from the building of Rome; and A. U. C. were uſed as abbreviating the words *anno ab urbe conditâ*. The Greeks uſed A, prefixed to a word, as a privative particle; alſo as a numeral letter, which ſtood only for an unit, or one.

In the ancient records of Rome, A ſtood for 500, but with a ſtroke thus Ā, it was accounted 5000.

In medical preſcriptions of phyſicians, A, or ā, or āā, denotes equal parts of the ingredients ſpecified: ā ſignifies *ana*, and is uſed for a contraction of the Greek prepoſition, *ανα*, of each; e. g. ℞. Mel. Sacchar. et Man. ā vel. āā ℥j. i. e. Take of ſugar, honey and manna, of each an ounce. See Syſtem of PHYSIC.

In chemiſtry, AAA, ſignifies an amalgama, or the operation of amalgamation. See Syſtem of CHEMISTRY.

In algebra, A, or *a*, ſignifies a known quantity. See Syſtem of ALGEBRA.

AABAM, the French chemiſts ſignify *lead* by it.

AAM, or HAAM, a meaſure of capacity, chiefly for liquids, and uſed among the Dutch, containing 63℔ avoirdupois weight, or 228 Engliſh pints = to 148$\frac{2}{3}$ French pints.

AAVORA, a kind of fruit produced by the American palm tree, the kernel of which is good to check a diarrhœa, being of a very aſtringent nature.

AB, in the Syriac calendar, is the name of the laſt ſummer month. The firſt day of which is called, *Saum Miriam*, the faſt of the Virgin; and is continued to the 15th, which they call *Fahr Miriam*, the end of the Virgin's faſt.

Ab, in the Hebrew chronology, the eleventh month of the civil year, and the fifth of the eccleſiaſtical year, which commences with Niſan. The month Ab, anſwers to the time from the new moon in July, to the new moon in Auguſt, and contains 30 days. The Jews obſerve a ſolemn faſt on the 9th of this month, in commemoration of the deſtruction of the Temple of Jeruſalem, in the year of the world 3446, or 558 years before Chriſt, by Nebuchadnezzar, king of Babylon. Alſo in remembrance of the deſtruction of the Temple, by the Romans, after the aſcenſion of Chriſt. On the 1ſt and 18th are two other faſts; the former in memory of Aaron's death, and the latter, becauſe of the extinguiſhing of the lamp in the ſanctuary, in the days of Ahaz.

Ab, is often uſed as an abbreviation for abbey; and when prefixed to the names of places, denote that they belong to abbies.

ABACA, the flax produced in the Philippine iſlands, and is prepared in the ſame manner as European flax, by ſteeping it, and then drying it for the break, after which it is hackled, and properly dreſſed; the teer makes fine hank yarn, and the tow is uſed in cordage, having the properties of hemp in the toughneſs and durability of its contexture.

ABACATUAIA, in ichthyology, the name given to a ſpecies of the zeus vomer, ſomewhat like the European doree, and is in ſize and ſhape ſomewhat the reſemblance of a plaiſe. It is of the Thoraic order of Linnæus; for its deſcription, ſee the article Zeus, and its reference to the tables of *fiſhes*.

ABACAY, a ſpecies of parrot, called callagay, in the Philippine iſlands.

ABACINARE, or Abbacinare, a word derived from the Italian *bacino*, a baſon; and *bacio*, a dark place; in writers of the fourteenth and fifteenth centuries, it implied a ſpecies of puniſhment, according to Du-Cange, conſiſting in blinding of the criminal, by holding a red hot baſon or bowl before his eyes.

ABACK, in ſea language, the ſituation of the ſails, when, by force of the wind, they are flatted againſt the maſts. The ſails are placed in this poſition by ſlackening their lee braces, and hawling in the weather ones, by which means the whole force of the wind is exerted on the fore part of their ſurface, and wholly tend to puſh the ſhip aſtern, and are often laid in this poſition to effect an immediate retreat without turning aſide. When the ſails are brought into this ſituation, either by a ſudden change of the wind, or by an alteration in the ſhip's courſe, the ſails are ſaid to be taken *aback*. When the ſhip rides with a ſingle anchor in a road, it is common to ſpread ſome ſail near the ſtern, ſuch as the mizen top ſail, &c. *aback*, in order to prevent her from approaching it by the motion of the tide, ſo as to entangle the flukes by her ſlackened cable, and by that means looſen it from the ground.

ABACOT, an ancient cap of ſtate, worn by the kings of England, the upper part of it was in the form of a double crown.

ABACTOR, or Abactores, a perſon or perſons who ſteal herds or droves of cattle; the Romans called ſuch, *abigeus*, or *abigevus*, and are properly diſtinguiſhed from *fures*, or petty thieves, who ſteal but one at a time. The phraſe is common in law books; the name is derived from the Latin word *abigo*, to drive away. The puniſhment annexed to ſuch a crime, was, in former times, to perpetually confine the offenders; but in ſome caſes it was death, namely, where the king's cattle were drove away. In Chambers' Dictionary, the editor (Dr. Rees) has it as a compound word, viz. *ab*, from, and *actor*, a driver, from *agere*, to drive; that this compoſition is wrong, remains no doubt.

ABACTUS, or Abigeatus, among the ancient phyſicians, was a word uſed for a miſcarriage procured by art, in contradiſtinction to *abſorſus*, natural. This diſtinction in the modern practice is very deſervedly exploded.

ABACUS, among the ancients, implied a kind of cupboard or beauſet. It is a Latin word, derived from the Greek αϐαξ, a table.

Abacus, in architecture, ſignifies a quadrangular piece, which ſerves as a crowning to the capitals of columns; and, in thoſe of the Corinthian order, repreſents a kind of a ſquare tile covering a baſket, ſuppoſed to be encompaſſed with leaves.

The original of which was: an Athenian matron happening to place a baſket, covered with a ſquare tile, over the root of an acanthus, or branca urſina, bearsfoot; which grew on the grave of a young Corinthian lady, the plant ſhooting up the following ſpring, encompaſſed the baſket all round, 'till meeting with the tile, it curled back in a kind of ſcroll. Calimachus, according to Vitruvius, a celebrated ſtatuary of Athens, paſſing by, obſerved the ſingularity of the appearance, and immediately executed a capital on that plan; repreſenting the tile by the abacus, the leaves of the acanthus by the volutes, or ſcrolls, and the baſket by the body of the capital.

In this manner was the firſt regular order in architecture invented, ſince called the Corinthian order.

There are two ſorts of acanthus, or bears-foot, the one wild, and armed with prickles, and the other ſmooth, and cultivated in botanical gardens. The former of which is repreſented in Gothic buildings, and the latter in thoſe of the Antique.

In the Tuſcan, Doric, and Ionic orders, every ſection of the abacus is parallel to the horizon, which is ſquare. The ſides are generally round, and ſometimes plain, without any ogee, agreeably to the taſte of the workman or artiſt. But a fillet is frequently added inſtead of an ogee. The height of it in the Tuſcan and Doric orders, is one half of that of the capital; in the Ionic, one fourth of it. In the Corinthian and Compoſite orders, the figure of the abacus is concave on the faces, having a roſe in the middle of each, and the four corners cut off. The height of it in the Corinthian ſhould be ſix fortieths, (or, according to Vitruvius, one ſeventh) of the whole capital. In the Compoſite order, the height ſhould be one twenty-fourth of that of the lower part of the column. The due proportion of it is, that its diagonal be twice its height. Scammozzi calls a concave moulding, an abacus, in the capital of the Tuſcan pedeſtal.

Abacus, or Abaciscus, in ancient architecture, denoted certain compartments in the Moſaic pavements. There were abaci of jaſper, alabaſter, porphyry, marble and glaſs, of various ſhapes and forms.

Palladio calls the plinth above the eclimus, or coultin, in the Tuſcan and Doric orders, by the ſame name. See Syſtem of Architecture.

Abacus, among mathematicians, was uſed in ancient times to draw diagrams upon it. The method was, to ſtrew it over with duſt, and take a ſkewer to perform the repreſentations neceſſary. In this ſenſe the word ſeems to be formed of the Phœnician אבק, *abak*, duſt.

Abacus is alſo the name of an ancient inſtrument for facilitating operations in arithmetic. It is variouſly contrived. That chiefly uſed in Europe, is made by drawing any number of parallel lines, at the diſtance of the two diameters of one of the counters uſed in the calculation. A counter placed on the loweſt line, ſignifies one; on the ſecond, ten; on the third, one hundred; on the fourth, one thouſand, &c. In the intermediate ſpaces, the ſame counters are eſtimated at one half of the value of the line immediately ſuperior.

The abacus is alſo divided croſſwiſe, into areolæ, by means whereof ſubtractions are made. *Wolf. Lex. Math. p.* 171. *Seq.*

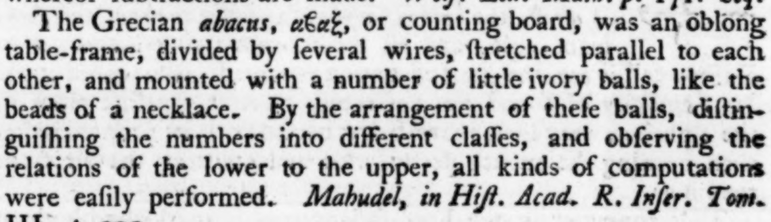
The Grecian *abacus*, *αϐαξ*, or counting board, was an oblong table-frame, divided by ſeveral wires, ſtretched parallel to each other, and mounted with a number of little ivory balls, like the beads of a necklace. By the arrangement of theſe balls, diſtinguiſhing the numbers into different claſſes, and obſerving the relations of the lower to the upper, all kinds of computations were eaſily performed. *Mahudel, in Hiſt. Acad. R. Inſcr. Tom.* III. *p.* 390.

The Roman *abacus* was much the ſame with the Grecian, except that inſtead of ſtrings, or wires and beads, in the Roman we find pins and grooves for them to ſlide in. It is deſcribed by ſeveral authors; but notwithſtanding theſe deſcriptions, we ſhould have had a very obſcure idea of the ancient manner of reckoning, had there not been figures of it found among the ancient marbles. *Phil. Tranſ.* N°. 180.

The Chineſe *abacus*, conſiſts, like the Grecian, of ſeveral ſeries of beads, ſtrung on braſs wires, extended from the top to the bottom of the inſtrument, and divided in the middle by a croſs piece from ſide to ſide; ſo that in the upper row, each ſtring has two beads, which are reckoned for five; and in the lower row, each ſtring has five beads of different values; the firſt being reckoned as 1, the ſecond 10, the third 100, &c. as above mentioned; but inſtead of four pins for digits, or units, in the Roman *abacus*, the Chineſe have five beads.

We have two different figures and deſcriptions of the Oriental *abacus*, one from Dr. Hook, and the other from F. Martinius, the latter reſident for many years in China. See Schwan-Pan.

But to illuſtrate the abacus table, reſpecting the values of the figures, on or between the lines, the following will ſuffice, viz. between the firſt and ſecond, 5, between the ſecond and third, 50, &c. The ſcheme is thus, upon which we ſhall record 1788.



Abacus *Pythagoricus*, the common multiplication table, ſo called from its being invented by Pythagoras.

Abacus *Logiſticus*, is a rectangled triangle, whoſe ſides, forming the right angle, contain the numbers 1 to 60, and its æra the facta of each two of the numbers perpendicularly oppoſite. This is called a *canon of ſexageſimals*.

Abacus *et Palmulæ*, denote, in ancient muſic, the machinery, whereby the ſtrings of polyplectra (or inſtruments of many ſtrings) were ſtruck with a plectrum, made of quills.

Abacus *Harmonicus*, is uſed by Kircher for the ſtructure and diſpoſition of the keys of a muſical inſtrument, whether to be touched with the hands, or the feet.

Abacus *Major*, in metallurgic operations, the name of a trough, uſed in the mines where the ore is waſhed.

ABADDON, or אגריכ, in the Greek *απολλυων*, names given to the devil in the 9th chapter of the Revelation of Saint John the Divine, both of which imply, *a deſtroyer*.

ABADIR, a title which the Carthaginians gave to gods of the firſt order. In the Roman mythology, it is the name of a ſtone, which Saturn ſwallowed by the contrivance of his wife Ops, believing it to be his new-born ſon Jupiter: hence, it ridiculouſly became the object of religious worſhip.

ABAFT, a ſea term, ſignifying the hinder part of a ſhip, or all thoſe parts both within and without, which lie towards the ſtern, in oppoſition to afore; which ſee.

Abaft, is alſo uſed as a prepoſition, and ſignifies further aft, or nearer the ſtern, as the barricade ſtands abaft the mainmaſt, i. e. behind it, or nearer the ſtern.

ABAGI, ſometimes called Abassi, worth 36 ſols, French money: four chaouris make one abagi, in the French American dominions.

ABALIENATION, in law, the act of transferring one man's property to another.

ABALIENATUS, among phyſicians, means corrupted; when applied to the body, it ſignifies, that a part is ſo deſtroyed as to require amputation; when applied to the ſenſes, it expreſſes their total deſtruction.

ABANGA, the name of the fruit of the palm-tree, in the iſland of St. Thomas.

ABAPTISTON, or Abaptista, a name anciently given to the terebella, a perforating part of the inſtrument, called a trepan, which by its conſtruction is prevented from ſinking into the brain, when the bone is cut through. The word is derived from the negative *α* and *βαπτω*, I immerge, implying to ſink under.

ABARCA, an ancient kind of ſhoe, uſed in Spain to paſs over the mountains, made of raw hides and bound with cords, which ſecured the travellers againſt the ſnow.

ABARNAHAS, a term uſed by alchemiſts for magneſia.

ABARTAMEN, a chemical term for lead.

ABARTICULATION, in anatomy, a ſpecies of articulation, the ſame with diarthroſis; which ſee.

ABAS, a weight uſed in Perſia for weighing pearls, being an eighth part lighter than an European carat.

Abas, a kind of epilepſy.

ABASED, Abaisse, in heraldry, an epithet applied to the wings of eagles, &c. when the tip looks downwards to the point of the ſhield, or when the wings are ſhut, the natural way of bearing them being extended.

ABASSI, a Perſian coin of the value of 16d. ½ ſterling.

ABATAMENTUM, a term in law, ſignifying an entry to lands by interpoſition, i. e. when a perſon dies ſeized, and another, who has no right, enters before the heir.

ABATE, in law, implies to overthrow, or pull down, both in the active and neutral ſenſe of the Engliſh common law: 1. In abating a writ, by exception. 2. Abating a demandant by an appeal in covin, whereby the accuſation is defeated by deceit.

Abate, generally means an error in or an exception to the pleadings.

Abate, in the manege, implies the performing any downward motion properly: thus a horſe is ſaid to abate, or take down his curvets, when he puts both his hind legs to the ground at once, and obſerves the ſame exactneſs in all the times.

ABATELEMENT, in commerce, a term uſed for a prohibition of trade to all French merchants in the ports of the Levant, who will not ſtand to their bargains or refuſe to pay their debts. This ſentence muſt be taken off by the French conſul, who impoſes it, before they can ſue any perſon for the payment of their debts.

ABATEMENT, in heraldry, an accidental figure, which is ſaid to have been added to coats of arms, in order to denote ſome diſhonourable demeanor or ſtain, whereby the dignity of the coat of armour was rendered of leſs eſteem.

Abatement, in the cuſtoms, an allowance made upon the duty of goods when the quantum damaged is determined by the judgment of two merchants upon oath, and aſcertained by a certificate from the ſurveyor and landwaiter.

ABATIS, the chief officer who looks to a king's ſtables.

ABATOR, in law, implies a perſon who takes poſſeſſion of another's inheritance, until the injured perſon brings a writ of *intruſione*; which ſee.

ABAVI, or Abavo, a ſynonime of the Adanſonia.

ABB, a term among clothiers, for the yarn of a weaver's warp; hence the wool, of which it is compoſed, is called abb-wool.

ABBA, in the Syriac and Chaldee languages, literally ſignifies father, and figuratively, a ſuperior, reputed as a father in reſpect of age, dignity or affection. It is alſo a Jewiſh title of honor, given to ſome of the claſs called Tanaites.

Abba, in the Coptic, Syriac and Ethiopic churches, means a biſhop.

ABBATIS, in a military ſenſe, is formed by cutting down many entire trees, the branches of which are turned towards the enemy, and, as much as poſſible, tangled one into another; they are made either before redoubts, or other works, to render the attacks difficult, or ſometimes along the ſkirt of a wood, to prevent the enemy from getting poſſeſſion of it. In this caſe, the trunks ſerve as a breaſt work, behind which the troops are poſted, and for that reaſon ſhould be diſpoſed ſo that the parts may, if poſſible, flank each other.

ABBE, ſynonimous, in a monaſtic ſenſe, with abbot; which ſee.

Abbe, a modern, curious, popular character in France, very little known in Great Britain. They are admiſſible in all companies, and no degradation to the beſt, notwithſtanding they are ſometimes found in the worſt. Their dreſs is rather of an academic, or of a profeſſed ſcholar, than of an eccleſiaſtic.

Theſe abbes are very numerous, and no leſs uſeful. They are, in colleges, the inſtructors of youth; in private families, the inſtructors of young gentlemen; and many of them procure a decent livelihood by their literary and witty compoſitions of all kinds, from the profoundeſt philoſophy to the moſt airy romances. They are, in ſhort, a body of men who poſſeſs a fund of univerſal talents and learning, and are inceſſantly employed in the cultivation of every various branch of literature and ingenuity. No ſubject whatever eſcapes them; ſerious or gay, ſolid or ludicrous, ſacred or profane, all pay tribute to their reſearches; and as they are converſant in the loweſt, as well as the higheſt topics, their fame is equally great in the learned and ſcribbling world. A diſtinguiſhed part of their character, is their devotion to the fair ſex, whoſe favourites in return they have the honour of being in the moſt enviable degree; the wit and ſmartneſs for which they are uſually remarked, agreeably ſuit the volatile caſt of the French ladies. In fine, theſe abbes are ſought after by moſt people on various accounts, as they are equally men of buſineſs and pleaſure, not leſs expert in the moſt ſerious tranſactions, than fond of enjoying their ſhare of whatever occupies the gay world. Hence they diligently frequent all public places, which are thought incomplete without them, as they compoſe the moſt intelligent part of the company, and are the moſt weighty approvers or condemners of what paſſes in almoſt every aſſemblage of people.

ABBESS, the ſuperior, or governeſs of an abbey, or convent of nuns. The abbeſs has the ſame rights and authority over her nuns, that the abbots regularly have over their monks. Her ſex precludes her from the performance of ſpiritual functions annexed to the prieſthood, wherewith the abbot is uſually inveſted; but there are inſtances of ſome abbeſſes who have a right, or rather a privilege, to commiſſion a prieſt to act for them. They have even a kind of epiſcopal juriſdiction, as well as ſome abbots, who are exempted from the viſitation of their dioceſans. Formerly they confeſſed their nuns, but now the deputed prieſt takes upon him that care: however, the abbeſs has a privilege to be preſent, if ſhe requires it. *St. Baſil's Rule of Faith.*

ABBEY, a monaſtery, or religious houſe, governed by a ſuperior, under the title of an abbot, or abbeſs. In the Latin records, called *abbathy*. By 31 Hen. VIII. Cap. 13. all forfeited to the king. Abbeys differ from priories, only in being under the government of an abbot, inſtead of a prior, which the ſuperiors of priories are called.

The inſtitution of theſe religious houſes was, doubtleſs, originally pious and uſeful, as they were intended for ſeminaries of religion, and aſylums for ſanctity; but, like many other good foundations, they have been wretchedly perverted, and are now nothing more than eccleſiaſtical colleges in which people retire from the world to ſpend their lives in ſolitude and idleneſs.

They prevailed in Great Britain before the reformation, particularly in England, and as they increaſed in riches, ſo the ſtate became poor; for the lands which theſe regulars poſſeſſed, were *in mortua manu*, i. e. could never revert to the lords who gave them. This inconvenience gave riſe to the ſtatutes againſt gifts in mortmaine, which prohibited donations to the religious houſes; and Lord Coke tells us, that ſeveral lords, at their creation, had a clauſe in their grant, that the donor might give or ſell his land to whom he would, *exceptis viris Religioſis et Judæis*, i. e. excepting Monks and Jews.

Theſe places were wholly aboliſhed in England, at the time of the reformation. Henry VIII. having firſt appointed viſitors to inſpect into the lives of the monks and nuns, which were found very diſorderly: upon which, the abbots perceiving their diſſolution unavoidable, were induced to reſign their houſes to the king, who, by that means, became inveſted with the abbey lands. Theſe were afterwards granted to different perſons, whoſe deſcendants enjoy them at this day; they were then valued at the enormous ſum of 2,853,000l. per ann. now upwards of 7 millions a year.

ABBOT, or Abbat, the ſuperior of a monaſtery of monks, erected into an abbey or prelacy.

The name abbot is originally Hebrew, where it ſignifies father. The Jews call father in their language אב, *ab*; the Caldeans and Syrians, *abba*; thence the Greeks *αϐϐας*, which the Latins retained *abbas*. Hence our abbot and the French abbé.

The Apoſtles uſed, in the Greek language, the Syriac word *abba*, by reaſon it was then commonly known in the ſynagogues, and the primitive aſſemblies of the Chriſtians, adding to it by way of interpretation, Aϐϐα ϖατηρ, (i. e. "Abba father.") Thus the Hebrew writers ſay, Pirk Abbath, or Avoth, (i. e. The chapters of the fathers.) It was an alluſion to this affectation of the Jews, that Jeſus Chriſt forbad his diſciples to call any man their father on earth, which St. Jerome turns againſt the ſuperiors of the monaſteries of his time, for aſſuming the title of abbots, or fathers.

The name abbot, although as ancient as that of monk, has been ſrequently confounded with it, as well as that of the clergy; but, in fact, it is a degree, between a layman and a perſon in orders.

In thoſe early days the abbots were ſubject to the biſhops and the ordinary paſtors, their monaſteries being remote from cities, and built in the fartheſt ſolitudes: they had no ſhare in eccleſiaſtical affairs. They went on Sundays to the pariſh church with the reſt of the people, or, if they were too remote, a prieſt was ſent them to adminiſter the ſacraments, till at length they were allowed to have prieſts of their own body. The archimandrite, or ſuperior, was uſually the prieſt; but his function extended no further than to the ſpiritual aſſiſtance of his monaſtery; and he remained ſtill in obedience to the biſhop: but this ſubjection was ſoon worn off, which occaſioned ſome ſevere laws to be made againſt them at the council of Chalcedon; notwithſtanding which, many of them carried the point of independency, and got the appellation of lord, with other badges of the epiſcopate, particularly the mitre. Hence aroſe the diſtinctions of mitred, croziered, œcumenical and cardinal abbots. Thoſe titles are as follow; the mitre implied epiſcopal authority, within the abbot's precinct; the crozier, the ſign of paſtoral care, as a ſtaff is given to ſignify the ſhepherd of ſouls; œcumenical, ſignified an univerſal or patriarchal juriſdiction. Cardinal abbots had juriſdiction over all other abbots.

In England, the mitred abbots were lords in parliament. Of theſe, Sir Edward Coke reckons 27, beſides two mitred priors.

There were other diſtinctions, namely, abbots elective, and abbots preſentative; but now underſtood by regular and commendatory. The firſt are real monks, who wear the habit of their order. The latter *in commendam* are ſeculars, though they have undergone the tonſure, and are obliged, by their bulls, to take orders when they come of age. The ceremony of their creation is properly called a benediction, which the vulgar term a conſecration.

A biſhop, whoſe ſee was formerly an abbey, is uſually ſtiled an abbot; ſuch are, Montreal and Catanea, in Sicily.

In Genoa, a chief magiſtrate, is called the abbot of the people.

In Paris, the rector of St. Geneviere, is called an abbot.

ABBREVIATION, or Abbreviature, a contraction of a word or paſſage, made by dropping ſome of the letters, or by ſubſtituting a mark or character in its ſtead; thus M. ſtands for *munipulus*, an handful.

ABBREVIATOR, in a general ſenſe, a perſon who abbreviates any large book into a narrow compaſs.

ABBREVIATORS, a college of 72 perſons in the chancery of Rome, who drew up the Pope's brieves, and reduced petitions, when granted by him, into proper form, for being converted into bulls: it ceaſed to exiſt in the latter end of the 15th century. The buſineſs is now done by ſeven notaries. *Ciampini*, *Lib.* 2. The chief perſon who is intruſted with the papers of the holy father, the pope, is called an *abbreviatore*, whoſe office is to aſſiſt the vice chancellor to prepare the pope's bulls.

ABBREUVOIR, in maſonry, the joint, or ſtructure, of two ſtones, or the inteſtice, or ſpace, left between them, filled up with mortar. It alſo implies a watering place.

ABBUTALS, ſignify the buttings or boundaries of land towards any point. Limits were anciently diſtinguiſhed by artificial hillocks, which were called *botentines*; hence, butting. In deſcriptions of ſcite land, the ſides on the breadth are more properly called *adjacentes*, and thoſe terminating the length are, *abbutantes*, which, in old ſurveys, were ſometimes expreſſed by *capitaire*, to head, whence *abbutals* are now called headlands.

ABCEDARY, or Abcedarian, an epithet given to compoſition; the parts of which are diſpoſed in the order of the letters of the alphabet: thus we ſay, Abcedarian pſalms, hymns, lamentations, &c.

ABDALS, in the Eaſtern countries, a kind of ſaints, ſuppoſed to be inſpired to a degree of madneſs. The word comes from *abdallah*, which, in the Arabic, implies the ſervant of God. The Perſians call them *devanch khoda*, agreeably to the Latins way of ſpeaking of their prophets and ſybils, *q. d. furentes Deo*, i. e. raging with God!

They are often carried by exceſs of zeal, eſpecially in the Indies, to run about the ſtreets and kill all they meet of a different religion, of which travellers furniſh many inſtances. The Engliſh ſeamen call this ſort of madneſs, *running a muck*, from the name of the inſtrument, a ſort of poignard which they employ on thoſe deſperate occaſions. If they are killed, as it commonly happens, before they have done much miſchief, they reckon it highly meritorious, and are eſteemed by the vulgar, martyrs for the faith.

ABDELAVI, an Egyptian melon; very acute at the extremities.

ABDEST, a Perſian word, properly ſignifying the water placed in a baſon for waſhing the hands, but it is uſed to imply the legal purifications practiced by the Mahometans, before they enter on their religious ceremonies.

ABDICATION, the action whereby a magiſtrate, or a perſon in office, renounces and gives up the ſame before the term of ſervice is expired.

This word is frequently confounded with reſignation, but differs from it, as being done purely and ſimply; whereas reſignation is in favour of ſome other perſon. It is ſaid to be a renunciation, quitting and relinquiſhing, ſo as to have nothing further to do with a thing, or the doing of ſuch actions as are inconſiſtent with holding of it. On king James II. leaving the kingdom and abdicating the government, the lords would have the word *deſertion* made uſe of, but the commons thought it was not comprehenſive enough, for the king might then have liberty of returning.

Abdication, in law, implies the expulſion of a child by his father, from the family; or diſcarding him. This cuſtom was common to the Greeks and Romans, who called it, *a familia alienato*; or, αποκηρυξις.

ABDITÆ Causæ, are the ſecret or remote cauſes of diſtempers, which phyſicians, of the rational ſect, affirmed were neceſſary to be known in order to eſtabliſh a right or proper method of cure.

ABDOMEN, in anatomy, is that part of the trunk of the body, which lies between the thorax and the bottom of the pelvis. The word is derived from *abdere*, to hide.

It is divided or ſeparated from the cavity of the thorax by the diaphragm, and terminated below by the muſcles of the arms.

The *abdomen* is a kind of a parabolic cavity, lined by a particular kind of a thin ſoft membrane, called the peritonæum. It contains the ſtomach, inteſtines, meſentery, meſocolon, omentum, liver, gall, bladder, ſpleen, pancreas, glands of the meſentery, vaſa lactea, receptaculum chyli, kidneys, renal glands, ureters, bladder, and the internal parts of generation in both ſexes.

The human body is generally divided into three regions or ventors, the head, thorax, and the abdomen.

The *abdomen* is defended by five pair of muſcles, which not only ſecure the viſcera, but by their alternate relaxations and contractions in reſpiration, promote the action of digeſtion, and the extruſion of the fæces and urine. By their contraction the cavity of the abdomen is ſtraightened, and the deſcent of the contents of the viſcera through the inteſtines is promoted. They are the proper antagoniſts to the ſphincters of the anus, and bladder, and forcibly expel the excrements of thoſe parts, as alſo the fœtus in parturition.

The *abdomen* is ſubject to inflammations, abſceſſes, ſcirrhi, indurations, inflations, ſpaſms, &c. ſo that many operations are performed on it, ſuch as, perforations, ſutures, ſections, &c.

It is liable to four different ſorts of wounds:

1. Such as affect the integuments, are not dangerous, and are to be treated as wounds are in common.

2. Such as affect the muſcles without penetrating the peritonæum, requires a probe to ſearch them, and injected liquids to cleanſe, and cure the wound.

3. Such as enter the cavity of the abdomen without injuring the contents. It muſt be treated as in the laſt caſe, but inſtead of keeping the wound open, as in that ſituation, it muſt be carefully kept cloſed up; and a ſparing regimen is particularly required, and the body gently purged during the time of healing.

4. The contents of the cavity entered; this caſe is of the utmoſt conſequence, as the greater danger reſults from it. The knowledge of which is gained, by the patient's exceſſive pain whilſt up, or ſuſpended in a horizontal poſture: this circumſtance is the pathognomic ſign of the diſeaſe; to remove which, in caſe of its continuing obſtinate, the place muſt be laid open, and the rupture reduced in the uſual way.

The muſcles which defend the abdomen are called, obliqui deſcendentes & aſcendentes, the rectus tranſverſalis and pyramidales.

Concerning the hydropieal tumors of the abdomen, valuable information may be had in the *Medical Eſſays of Edinburgh*, *Vol. V. Art.* 59. *and Buchan's Domeſtic Medicine.* See Syſtems of Anatomy and Surgery.

ABDOMINALES, in the Linnæan ſyſtem of ichthyology, an order of fiſh, having the ventral fins placed behind the pectoral, in the abdomen; comprehending 17 genera, and 127 ſpecies. See Syſtem of Ichthyology.

ABDUCENS Labiorum, in anatomy, a name given to a muſcle, called by Albinus, *levator anguli oris*; by Spigelius, *ſecundus ad latera*; and the *caninus*, or *elevator labiorum communis*, of others

ABDUCTION, a form of reaſoning among logicians, which conſiſts in drawing concluſions from certain and undeniable propoſitions.

Abduction, in ſurgery, a ſpecies of fracture, wherein the broken parts of the bone recede from each other.

ABDUCTOR, in anatomy, commonly called Abducent, a name uſually applied to ſeveral of the muſcles, on account of their ſerving to withdraw, open, or pull back the parts to which they are fixed.

The word is compounded of *ab*, from, and *ducere*, to draw. Their antagoniſts are adductores.

The buſineſs of the abductory muſcles is to remove and extend the limbs, fingers, toes, eyes, &c. of the human body. See Syſtem of ANATOMY.

ABEL-TREE, an obſolete name for a ſpecies of the poplar tree. See POPULUS.

ABELIANS, ABELOITES, or ABELONIANS, in church hiſtory, a ſect of heretics, mentioned by St. Auguſtin, which aroſe in the dioceſe of Hippo, in Africa, and is ſuppoſed to have begun in the reign of Arcadius and ended in that of Theodoſius. Their marriages were regulated after the example of Abel, who they pretended was married, but died without ever having known his wife. They therefore allowed each man to marry one woman, but enjoined them to live in continence, and to keep up the ſect when a man and woman entered into this ſociety; they adapted a boy and a girl who were to inherit their goods, and to many upon the ſame terms of continence, but to fulfil all things in the manner of their predeceſſors.

ABELICEA, SANTALUS ADULTERINA, or PSEUDOSANTALUM, a tall ſpecies of pine, growing only in Crete.

ABELMOLUCH, or ABELMULICH, a ſpecies of the palm, or ricinus tree.

ABELMOSCH, or ABELMUSCH, muſk ſeed, brought from the Weſt Indies, formerly imported from Egypt.

ABENEL GAUBY, a fixed ſtar of the third magnitude, in the ſouth ſcale of Libra, or the ſixth Conſtellation.

ABEREMURDER, ABEREMURDRUM, is, in law, *probatum murdrum*, or murder that need no proof, and could only be atoned for with the blood of the guilty; it is part of the code of Alfred the Great.

ABERRATION, in aſtronomy, a ſmall apparent motion of the fixed ſtars, diſcovered by the late Doctor Bradley. The diſcovery was made by accident in the year 1725, when Mr. Molyneux and Dr. Bradley, began to obſerve the bright ſtar in the head of Draco, marked γ by Bayer, as it paſſed near the zenith, with an inſtrument made by Mr. Graham, in order to diſcover the parallax of the earth's annual orbit; and after repeated obſervations they found this ſtar about the beginning of March 1726, to be 20″ more ſoutherly than at the firſt obſervation. It now ſeemed to be arrived at its utmoſt limits ſouthward, becauſe in ſeveral trials made about this time, no ſenſible difference was obſerved in its ſituation. By the 14th of April 1726, it appeared to be turning back, and on the 1ſt of June it paſſed at the ſame diſtance from the zenith, as it had done in December, when it was firſt obſerved. In September following, it appeared 39″ more to the N. than it was in March, juſt the contrary way to what it ought to appear by the annual parallax of the ſtars. This unexpected phænomenon perplexed the obſervers very much, and Mr. Molyneux died before the true cauſe of it was diſcovered. After this, Dr. Bradley, with another inſtrument more exact, obſerved the ſame appearances in many other ſtars; and by the great regularity that appeared in a ſeries of obſervations, made in all parts of the year, the doctor was fully ſatisfied with regard to the general laws of the phænomena, and therefore endeavoured to find out the cauſe of them. He was already convinced that the apparent motion of the ſtars, was not owing to a nutation of the earth's axis.

The next thing that offered itſelf, was an alteration in the direction of the plumb line, with which the inſtrument was conſtantly rectified, but this upon trial proved inſufficient. Then he had recourſe to what refraction might do, but here alſo nothing ſatisfactory occurred. At laſt, this acute aſtronomer found that the phænomena in queſtion proceeded from the progreſſive motion of light, and the earth's annual motion in its orbit: for he perceived, that if light was propagated in time, the apparent place of a fixed object would not be the ſame when the eye is at reſt, as when it is moving in any other direction than that of the line paſſing through the eye and object, and that when the eye is moving in different directions the apparent place of the object would be different. See *Philoſ. Tranſ.* N°. 406.

ABERRATION, in medicine, ſignifies a deviation from the uſual courſe of the natural ſyſtem.

ABERRATION, in optics, is uſed to denote that error, or deviation of the rays of light, when inflected by a lens or ſpeculum, whereby they are hindered from meeting or uniting in the ſame point.

There are two ſpecies of the aberrations of rays of light, diſtinguiſhed by their different cauſes; one ariſing from the figure of the glaſs or ſpeculum, the other from the unequal refrangibility of the rays of light. This laſt ſpecies is ſometimes called the Newtonian ſyſtem of optics. See Syſtem of OPTICS.

ABERRATION, *Crown of*, is a luminous circle ſurrounding the real diſk of the ſun, depending on the aberration of the ſolar rays, whereby his apparent diameter is enlarged.

ABESAMON, dirt, rubbiſh, or dung.

ABESSI, implies the remaining matter of the aliment, after the chyle is ſeparated from it, i. e. excrement, uſually ſtiled, rebis.

ABESTA, the name of one of the ſacred books of the Perſian magi, which they aſcribe to their great founder Zoroaſter. The abeſta is a commentary on two others of their religious books called Zend and Pazend, the three together including the grand ſyſtem of the Ignicold, or worſhippers of holy and celeſtial fire.

ABESTON. See ASBESTOS.

ABESUM, unſlacked calx, or quick lime.

ABETTOR, a law phraſe, implying one who encourages another to perform a criminal action; and lays, in all caſes, liable to puniſhment, except in high treaſon againſt the ſtate; as thoſe guilty in that particular are wholly principals, incapable of abettors or acceſſaries. See ACCESSARY and the ANALYSIS *of law*.

ABEVACUATION, uſed as a medical term, to ſignify a partial evacuation of the peccant humors, either by art or nature.

ABEYANCE, ABBAYANCE, or ABEIANCE, in law, the expectancy of an eſtate, e. g. if lands are leaſed to one perſon as tenant for life, with reverſion to another for years, the remainder for years is in abeyance till the deceaſe of the leſſee.

ABHEL, in botany, the evergreen called ſavin, well known in phyſical preparations.

ABIANS, the ancient people of Scythia, who dwelt in wooden houſes that moved upon wheels, ſo as to facilitate a journeying onward, being mindful only of their flocks, on whoſe produce they ſubſiſted. Homer makes honourable mention of them, as a people of great integrity; alſo humane and courageous.

ABIB, in the ancient chronology of the Jews, the firſt month of the eccleſiaſtical year; ſince called Niſan; and is reckoned the ſeventh month of the civil year. It began at the vernal equinox; and according to the courſe of the moon, by which their months were regulated, anſwered to the latter part of our March, and the beginning of April.

ABIB, in Hebrew, ſignifies an ear of corn; alluding to the firſt harveſt commencing in that month throughout Paleſtine.

ABIDING *by Proofs*, in law, the caſe added to the pleadings; whereby council illuſtrates the matters in evidence, ſo as to convince the court that the ſtatement of the caſe, as to facts, carries a verdict in favour of his client.

ABIES, the fir-tree, a genus of ever-greens; the characters of which are, there are male and female on the ſame tree; the males have empalements of four leaves without petals, many ſtamina, and naked ſummits. The females are collected in a ſcaly cone, each ſcale covering two flowers, having neither petals or ſtamina, with one pointel, and are each ſucceeded by a winged nut. The diſtinguiſhing character of this genus, is the leaves ariſing ſingly from their baſe, whereas the pines have two or more ariſing from the ſame point.

By the Linnæan ſyſtem, firs and pines are united, ſo as to be claſſed generally as deals, yet differ materially as to ſubſtance and quality; the learned botaniſt placing them among the manœcia monadelphia.

The fir tree grows in many parts of Europe, particularly Germany, Norway, Denmark and Sweden, as well as in Aſia and America, as a natural production: in the latter of which places the celebrated ſpruce beer is brewed from a preparation made from this tree. The tops and leaves of the fir tree, are recommended to be taken in diet drinks for the ſcurvy.

Roſin, tar, common and Burgundy pitch, Straſburgh turpentine, Canada balſam, &c. are productions of this tree.

All ſorts of fir are propagated by ſeeds; which may be done in manner following, viz. Soak the cones in warm water for about twelve hours, after which the ſeveral cells will open, and the ſeeds will fall out; for theſe ſeeds ſhould never be taken out of the cones, till the time of ſowing them, which is in March. The ground ſhould be carefully fallowed and harrowed ſeveral times, to deſtroy the weeds, then level the earth with a ſpade, at the diſtance of about ſix feet ſquare, in ſmall ſpots, in which, ten or twelve ſeeds are to be ſown, covered with ſome of the ſame mould, broken fine, but not ſifted. A defence muſt be placed over them, ſo as to defend them from the birds; a net or a furze buſh will be the beſt ſafeguard, until they are well up; and when this covering is taken off, a little looſe earth is to be drawn about the ſtems of the plants, and a row of ſmall furze, placed on the ſouth ſide, to defend them from the heat of the ſun at noon. About eight plants come to perfection out of twelve, which may be left ſtanding until the ſecond year; and then are to be tranſplanted into nurſery beds. On the fourth year ſhould be removed to the plantation allotted them, and are to be planted at 20 feet diſtance, for when they are cloſer planted, the under branches ſoon drop their leaves, and totally decay: in removing the plants, great care ſhould be taken not to injure their roots, and as much earth raiſed with them as is poſſible.

The unſkilful diſpoſition of theſe trees, has brought them into diſrepute with many perſons, but, if properly placed, they may be made ornamental to gentlemen's ſeats.

In pruning off the under branches, to the deſigned height, not more than one row ſhould be lopt off each year, as too many cut off at once may kill or dwarf the tree into a ſtate of wry bendings. The month of September is the time for pruning; and March, or the beginning of April, for ſowing and tranſplanting.

The common fir requires a ſtrong loamy ſoil, in low grounds. The American ſpruce firs, picea, or ſilver yew leaved firs, a dry ſituation, but a very deep ſoil and muſt be ſheltered from the north winds in the winter ſeaſon.

They will riſe in a beautiful pyramidal figure, if kept free from weeds, and fenced from cattle: and will amply ſatisfy the gardner for his trouble. But if at ſeven years old, any are found to be ſtunted in growth, it will be well to dig them up carefully, and exchange places with others that flouriſh; but then ſome rich ordure, or manure, is to be added in this plantation.

ABIGA *Herba*, the ground pine or chamæpitys.

ABIGEAT, or Abigeatus, the ſame as *abactus*, the crime of ſtealing cattle by droves; in the ancient laws of England, puniſhed by baniſhment, condemnation to the mines or gallies for life, and ſometimes with death itſelf.

Abigeat, among phyſicians, to procure abortion by art.

ABIGEUS, in the civil law, one guilty of the crime of drove ſtealing.

ABILITY, in law, denotes a power of doing certain actions in the acquiſition or transferring of property: generally, capacity.

AB-INTESTATE, in the civil law, is applied to a perſon who inherits the right of one who died inteſtate, or without making a will.

ABISHERING, an ancient law term, denoting a liberty or freedom from all amerciaments; alſo a right to the forfeiture of all others within his fee; uſually applied to perſons to whom charters or other inſtruments of record were granted. Several citizens in England partake of thoſe franchiſes.

ABIT, or Aboit, ceruſs.

ABJURATION, in law, is uſed for renouncing, diſclaiming, and denying the pretender to have any manner of right to the throne of Great Britain or Ireland, and that upon oath, which is required to be taken upon divers pains and penalties by many ſtatutes, particularly 1 W. & M. 13 W. III. 1 Anne, and 1 G. I. But as the form has been altered ſomewhat by 6 G. III. chap. 53, the following is the exact form of the oath:

"I L. M. do truly and ſincerely acknowledge and profeſs, teſtify and declare in my conſcience, before God and the world, that our Sovereign Lord King George, is lawful and rightful king of this realm, and all other his majeſty's dominions thereunto belonging. And I do ſolemnly and ſincerely declare, that I do believe in my conſcience, that not any of the deſcendants of the perſon who pretended to be Prince of Wales, during the life of the late king James II. and ſince his deceaſe pretended to be, and took upon himſelf the ſtile and title of king of England, by the name of James III. or of Scotland, by the name of James VIII. or the ſtyle and title of king of Great Britan, hath any right or title whatſoever to the crown of this realm, or any other the dominions thereunto belonging. And I do renounce, refuſe and abjure any allegience or obedience to any of them. And I do ſwear, that I will bear faith and true allegiance, to his majeſty king George, and him will defend, to the utmoſt of my power againſt all traiterous conſpiracies and attempts, whatſoever, which ſhall be made againſt his perſon, crown and dignity; and I will do my beſt endeavour, to diſcloſe, make known to his majeſty and his ſucceſſors, all treaſons and traiterous conſpiracies, which I ſhall know to be againſt him or any of them. And I do faithfully promiſe, to the utmoſt of my power, to ſupport, maintain and defend the ſucceſſion of the crown, againſt the deſcendants of the ſaid James, and againſt all other perſons whatſoever, which ſucceſſion by an act, intitled 'An act for the further limitation of the crown, and the better ſecuring the rights and liberties of the ſubject,' is and ſtands limitted to the princeſs Sophia, electoreſs and ducheſs dowager of Hanover, and the heirs of her body, being proteſtants. And all theſe things I do plainly and ſincerely acknowledge and ſwear, according to theſe expreſs words by me ſpoken, and according to the plain and common ſenſe and underſtanding of the ſame words, without any equivocation, mental evaſion, or ſecret reſervation whatſoever. And I do make this recognition, acknowledgment, abjuration, renunciation, and promiſe, heartily, willingly, and truly, upon the true faith of a Chriſtian. So help me God."

The word is purely Latin, *abjuratio*; and compounded of *ab*, from, or contrary; and *jurare*, to ſwear.

Abjuration, in our ancient cuſtoms, implied an oath taken by a perſon guilty of felony, and who had fled to a place of ſanctuary, whereby he ſolemnly engaged to leave the kingdom for ever; he was then at liberty for forty days to prepare himſelf.

Abjuration *of Hereſy*, the ſolemn recantation of any doctrine accounted wicked, falſe, or dangerous.

ABLACTATION, from *ablactatio*, the weaning a child from the breaſt: as nature has taken care to provide for an aliment ſuitable to the ſtomachs of new born infants, ſo it has pointed out directions when to change it, for a diet is more ſolid and difficult of digeſtion. For the method of weaning. See Weaning.

Ablactation, in ancient agriculture, or gardening, implies a method of inarching, grafting, or engrafting by approach. See Grafting *and* Inoculation.

Ablactation, ſignifies alſo any thing extracted from its original ſtate, and ſupported by ſome new ſource, ſo as to make its nature partake of another means to preſerve life, than that it originally poſſeſſed: this is only to be applied to the botanical ſyſtem.

ABLAQUEATION, a phraſe of antiquity in gardening, which ſignifies the operation of laying the roots of fruit trees bare, to expoſe them to the ſun, wind and rain, in order to promote their fecundity. The time of performing this ſuppoſed ſervice to the trees of baring, uſed to be in the latter end of autumn, but now it is very properly laid aſide, as many excellent fruit trees were killed by it.

ABLATIVE, is the ſixth caſe in the Latin grammar, and peculiar to that language. It is oppoſed to the *dative*, which expreſſes the action of giving; the *ablative* expreſſing that of taking away: e. g. *ablatum eſt à me*, it was taken from me. It is ſometimes called the comparative caſe, as being much uſed in comparing things together; thus, *dulcior melle*, ſweeter than honey. See Syſtem of Grammar.

Ablative *Abſolute*, in grammar, is a detached phraſe, independent of the reſt of a diſcourſe; and is much the ſame with the Engliſh parentheſis; e. g. *Juvante Deo*, (with God's aſſiſtance). It is called *abſolute*, becauſe governed by no other word.

ABLECTI, in Roman antiquity, a ſelect body of ſoldiers picked or ſelected out from among thoſe called *extraordinarii*.

ABLEGMINA, in Roman antiquity, thoſe choice parts of the entrails of victims, which were offered in ſacrifice to the gods; called proficiæ, porriciæ, profecta & proſegmina. The ablegmina were ſprinkled with flour, and burnt on the altar, the prieſts pouring wine on them.

ABLET, or Ablen, in ichthyology, a name given to the common bleak, a ſmall freſh water fiſh, called by the Romans alburnus. It is a ſpecies of Cyprinus, which Artedi calls the five inch Cyprinus, with twenty rays in the pianna ani. See thoſe names.

ABLUENTS, *Abluentia*, in medicine, the ſame with dilutents or diluters; and are ſuch as diſſolve, and conſiſt of aqueous infuſions and decoctions, to thin the blood, correct its ſpiſſitude and acrimony, and carry off the acrid ſalts and offending matter, by the emunctories of nature; but eſpecially in the ſtomach and inteſtines.

ABLUTION, from *abluo*, *quaſi ab lavo*, I waſh away; in a general ſenſe, implies the waſhing or purifying with water.

Ablution, in a religious application, ſignifies a ceremony in uſe among the ancients; and ſtill practiſed in ſeveral parts of the world: it conſiſted in waſhing the body, which was always done before ſacrificing, or even entering their houſes; which practice ſeems to be as old as any part of external worſhip, or ceremonial law.

Moſes enjoined them; the Heathens adopted them; and Mahomet gave commandment for their uſe to his followers: thus they have taken root among moſt nations; and have become a conſiderable part of almoſt all forms of religious worſhip that are eſtabliſhed throughout the world. The Egyptian magi had their diurnal and nocturnal ablutions. The Grecians their ſprinklings. The Romans their luſtrations and lavations. The Jews their waſhings. The ancient Chriſtians their bathings before communion: which the Roman catholics, in ſome meaſure, ſtill retain. The Syrians, Copths, &c. have their ſolemn waſhings on good Friday; the Turks their greater and leſſer abſitions, their ghaſt, and wodon, their aman, tharata, taharat or tabarut, guſul, abdeſt, and ramanis.

Ablution, in the Romiſh church, is now uſed by taking a ſip of wine and water, to waſh down the wafer, eaten in the communion ſervice, as the hoſt is ſuppoſed to be really tranſubſtantiated into the elements of the body and blood of Jeſus Chriſt, after the conſecration of the prieſt.

The ſame term is applied to the action of the prieſt's waſhing his hands in water, after the conſecration of the hoſt.

Ablution, among chemiſts and apothecaries, is the waſhing away of the ſuperabundant ſalts of any body, an operation often called edulcoration.

Ablution, among phyſicians, is uſed either by waſhing the external parts of the body by baths, or deterging the body by their diluting fluids, as water-gruel, whey, &c. Frequent ablutions, with warm water, are ſaid to diſpoſe the body to putrid diſeaſes, by relaxing its fibres, which is thought to be one reaſon why the plague is ſo frequent in the Turkiſh dominions; the Mahometan religion enjoining frequent ablutions.

ABOARD, the inſide of a ſhip: hence any perſon who enters a ſhip is ſaid to go aboard; but when an enemy enters in the time of battle, he is ſaid to board; a technical term that always implies hoſtility. To fall aboard of, is to ſtrike at, or encounter another ſhip, when one or both are in motion; or to be driven upon each other by the force of the wind or current.

Aboard *the main tack*, the order to draw a ſail, called the main tack, or ſail, which is done by drawing the lower corner of the main ſail down to the cheſtree.

ABOIT, ceruſs, or white lead.

ABOLISHING, the ſame with

ABOLITION, which implies the act of annulling, deſtroying, making void, or reducing to nothing, in a general ſenſe: but,

Abolition, *in law*, ſignifies the repealing of any act or ſtatute, and prohibiting ſome ceremony or cuſtom. It alſo implies the leave of his majeſty or his judge, to a criminal accuſer, to forbear any further proſecution. Vide 25 Hen. VIII. c. 21.

Abolition, in the ancient practice of civilians and lawyers, implied, a deſiſting from, or annulling a legal proſecution; thereby to remit the puniſhment due to the crime. Alſo the cancelling or diſcharging a public debt.

ABOLLA, a military garment worn by the Greek and Roman ſoldiers; it was lined with ſome of the ſame ſtuff, to encreaſe its warmth in the winter ſeaſon.

Some affirm that it took its name from the Latin word *bulla*, on the ſuppoſition that the garment was ornamented with bullæ; others aſſert that it derived its name from the Greek *αμβολη*, of *αναβολη*, *amictus*, cloathing.

Critics and antiquaries are greatly divided as to its form, uſe, kinds, &c. of this garment. Papias makes it a ſpecies of the toga, or gown; but Nonius, and others, a ſpecies of the pallium, or cloak.

The abolla ſeems rather to have been oppoſed to the toga, which was a garment of peace, as the abolla was of war, for ſo Varro and Martial report of them. There ſeem to have been different kind of abollas, fitted to different occaſions; for even kings appear to have uſed them. Caligula was affronted at king Ptolomy, for appearing at the ſhews in a purple abolla, and by the eclat thereof, turned the eyes of the ſpectators from the emperor upon himſelf.

ABOMASUS, Abomasum, or Abomasius, in comparative anatomy, names uſed for the fourth ſtomach of ruminating beaſts, or ſuch as chew the cud: theſe have four cells or ſtomachs, 1, the venter; 2, the reticulum; 3, the omaſus; and 4, the abomaſus, or maw. And in the latter of calves and lambs, the runnet is uſed for curdling milk.

ABOMINATION, a term uſed in Scripture with regard to the Hebrews, who, being ſhepherds, are ſaid to have been an abomination to the Egyptians, becauſe they ſacrificed the ſacred animals of that people, as oxen, goats, ſheep, &c. which were unlawful to be ſlain in that country. Again, the abomination of deſolation, ſpoken of by the prophet Daniel, is ſuppoſed to imply the ſtatue of Jupiter Olympus, which Antiochus Epiphanes cauſed to be placed in the temple of Jeruſalem. The abomination of deſolation, mentioned by the Evangeliſts, ſignifies the enſigns of the Romans, during the laſt ſiege of Jeruſalem, by Titus, on whom their gods were decyphered, and placed on the holy temple, as trophies of victory and honour.

ABORIGINES, or Aborigenes, in geography, a name given to the original, or firſt inhabitants, of any country; but more particulary the ancient inhabitants of Latium, when Æneas and his Trojans came into Italy; ſince called Romania, or Campagna di Roma.

In this ſenſe the Aborigenes are diſtinguiſhed from the Janigenæ, who, according to the falſe Beroſus, inhabited the country before them from the Siculi, whom they expelled; from the Grecians, whom they deſcended from; from the Latins, whoſe name they aſſumed, after their union with Æneas and the Trojans; laſtly, from the Auſonii, Volſci, Œnotrii, &c. neighbouring nations in other parts of the country. St. Jerome ſays, they were ſo called from being *abſque origine*; the primitive planters of the country after the flood. Dion. Halicamuſſus, accounts for the name as original founders of the race of inhabitants of that country: others ſay they were originally Arcadians, who claimed to be earth-born, and not deſcended from any people. Aurel. Victor ſuggeſts another opinion, namely, Aborigines, q. d. Aberrigines, from *ab*, from, and *errare*, to wander, as having been a wandering people. Pauſanias rather thinks they were thus called *απο ορεων*, from mountains; which opinion ſeems to be confirmed by Virgil, who, ſpeaking of Saturn, the legiſlator of this people, ſays:

> IS GENUS INDOCILE AC DISPERSUM MONTIBUS ALTIS,
> COMPOSUIT, LEGESQUE DEDIT. ———

ABORTION, from *ab*, and *orior*, to be born; in midwifry or medicine, implies an untimely or premature birth of a fœtus, otherwiſe called a miſcarriage: but if this happens before the ſecond month of pregnancy, it is called a falſe conception. Abortions are ſeldom dangerous in the firſt five months; but a frequent habit of miſcarriage debilitates the ſyſtem, ſhatters the conſtitution, and lays the foundation of chronic diſeaſes of the moſt obſtinate and dangerous nature.

In the advanced months, the prognoſis will be more or leſs favorable, according to the patient's former ſtate of health.

The proximate cauſe of abortion is the ſame with that of real travail, namely, a contracting effort of the uterus, and abdominal muſcles, aſſiſted by the other expulſive powers. The remote cauſes cannot be explained with preciſion, as many circumſtances with regard to the nature of impregnation and connection of the fœtus, with the placenta and uterus, are ſubjects involved in many difficulties; ſo that the general maxims which follow, are the heads that require particular attention.

1. Whatever interrupts the regular circulation, between the uterus and placenta.

2. Every thing that excites the ſpaſmodic contraction of the uterus, or other aſſiſting powers.

3. All accidents, or occaſions, that deprive the fœtus of life.

Theſe matters properly conſidered, will lead to a further inveſtigation of particulars, which ſhall be amply demonſtrated in its proper place.

With regard to the treatment of abortions, it is impoſſible to ſet down any general preſcription, as it muſt be varied agreeably to the particular circumſtances of the caſe; nor is it poſſible to point out particular indications, or propoſe any regular plan to be purſued for this purpoſe.

Abortion is often preceded by no apparent ſymptom, till the rupture of the membranes and evacuation of the waters, announce the approaching expulſion of the fœtus. Either to remove threatening ſymptoms, or to prevent miſcarriage, when there is reaſon to apprehend it, often baffles the moſt ſkilful practitioner; becauſe it generally happens, there is a ceſſation of growth in the ovum; or, in other words, an extinction of life in the fœtus, ſometime previous to any appearance of abortion.

Women who have once aborted, are liable to a recurrence from a like cauſe, at the ſame particular period; therefore, upon the firſt appearance of it, a woman ought to confine herſelf to her bed, until the reſult of the ſymptom was ſufficiently explained. Opiates, mixed with reſtringents, are reckoned excellent againſt abortion. Boerhaave's recipe is, ℞. bloodſtone, powdered, Armenian bole, dragon's blood, of each 1 drachm; ſyrup of myrrh, an oz. ſolid laudanum, 3 grains; plaintain water, 6 oz. well mixed together: half an oz. to be taken every quarter of an hour. For the further treatment of abortions, ſee Syſtem of MIDWIFRY.

The practice of procuring abortions, was prohibited in both ancient Greece and Rome; but no other penalty annexed than exile; for it was conſidered in thoſe Pagan countries, no more than the plucking of unripe fruit; therefore philoſophy exempted it from being a capital offence.

Seneca repreſents it as a peculiar glory of Helvia, that ſhe had never, like other women, who attended to their ſhape and beauty, deſtroyed the fœtus in her womb. The primitive father, Athenagoras Tertullian, Minutius Felix, and Auguſtin, declaimed loudly againſt the practice, as virtual murder; and ſeveral councils have juſtly condemned it: yet it is affirmed by many, that the modern church of Rome allows diſpenſations for that ſin. The rates of which Egane has given in his Religious Ceremonies.

Artificial abortion is chiefly in the hands of midwives and nurſes, rarely in that of phyſicians, who in ſome countries are not admitted to the profeſſion without abjuring it. Hippocrates, in the oath he would have enjoined on all phyſicians, includes their not giving the *peſus abortivus*; though elſewhere he gives the formal proceſs whereby he himſelf procured a young woman a miſcarriage. The Cyclopædia has introduced an unneceſſary method to procure an abortion, which curious recipe we omit, as we think, with a great deal of propriety, leſſons of murder are in no wiſe compatible with univerſal ſcience.

ABORTION, is alſo uſed for a fœtus, which dying in the womb, continues there beyond the uſual time of geſtation.

ABORTION, among gardeners, ſignifies ſuch fruits as are produced too early, and never arrive at maturity.

ABORTIVE, in a general ſenſe, a term uſed for any thing which comes before its due time; or a deſign which miſcarries.

ABORTIVE, is more particularly uſed for any thing relating to an abortion, to which it is uſually applied.

ABOUT, the ſituation of a ſhip immediately after ſhe has tacked or changed her courſe, by going about and ſtanding on the other tack.

ABOUT-SHIP, the order to the ſhip's crew to prepare for tacking; to change the ſhip's courſe.

ABRA, a ſilver coin ſtruck in Poland, worth about a ſhilling, Britiſh money, current in ſeveral parts of Germany, Conſtantinople, Aſtracan, Smyrna, and Grand Cairo.

ABRAHAMIANS, or ABRAHAMITES, a ſect of heretics, who renewed the error of the Paulicians. They took their name from that of their leader Abraham, a native of Antioch; by the Arabs called Ibrahim, whence alſo the name Ibrahimiah given to this ſect. They aroſe about the cloſe of the 8th century, and were ſuppreſſed by the vigilance of Cyriacus, patriarch of Antioch.

ABRAHAMITES, in church hiſtory, is uſed for a party of monks, who ſuffered death for the worſhip of images under Theophilus.

ABRAMIS, in ichthyology, a name given by Bellonius and others, to the cyprinus latus, or bream.

ABRASA, ulcers, attended with abraſion of part of the ſubſtance, or ulcers, where the ſkin is ſo tender and lax, as to be ſubject to abraſion.

ABRASAX, or ABRAXAS, the ſupreme god of the Baſilidian heretics. It is a myſtical word, compoſed of the Greek numerals, α, (1) β, (2) ϱ, (100) α, (1) ξ, (60) α, (1) σ, (200) = CCCLXV. or 365.

ABRASION, in medicine, the corroding of any part by acrid humours or medicine. To remedy which, emollient and obtunding medicines are recommended. It alſo implies to ſhave off.

ABRAUM, in natural hiſtory, a name given by ſome writers to a ſpecies of red clay, uſed in England by cabinet makers and other tradeſmen, to colour mahogany of a reddiſh colour.

ABRAX, an antique ſtone, with the word abraxas engraved on it; they are of various ſizes, and moſt of them as old as the third century.

ABREAST, a ſea term, ſignifies, ſide by ſide, or oppoſite to;

a ſituation in which two or more ſhips lie, with their ſides parallel to each other, and their heads equally advanced. This term more particularly regards the line of battle at ſea, where, on the different occaſions of attack, retreat, or purſuit, the ſeveral ſquadrons or diviſions of a fleet are obliged to vary their diſpoſitions, and yet maintain a proper regularity by ſailing in right or curved lines. When the line is formed abreaſt, the whole ſquadron advances uniformly, the ſhips being equally diſtant from and parallel to each other, ſo that the length of each ſhip forms a right angle, with the extent of the ſquadron or line abreaſt. The commander in chief is always ſtationed in the center, and the ſecond and third in command in the centers of their reſpective ſquadrons.

Abreast, within the ſhip, implies on a line with the beam, or by the ſide of any object aboard. See Abaft.

ABRIC, ſulphur.

ABRIDGING, in literature, the ſhortening, epitomizing, or contracting any book, matter, or thing.

Abridging, in algebra, is the reducing a compound equation to a more ſimple form; to prevent the mind's being diſtracted, with attending to known quantities, concerning which nothing further is required: and to keep the attention entire for the reſt, mathematicians uſed to abridge their equations by expreſſing all the known quantities of the ſame term, by a ſingle letter. See Algebra.

ABRIDGMENT, a ſummary or contraction of a diſcourſe, wherein the leſs material things being more briefly inſiſted on, the whole is brought to a leſſer compaſs.

Abridgment, in a literary ſenſe, is the ſame with epitomè, or abſtract of a large work, the perfection of which conſiſts in taking only what is material and ſubſtantial, and rejecting all ſuperfluities.

Abridgment, in law, the ſhortening a count or declaration. Thus in aſſize, a man is ſaid to abridge his plaint, and a woman her demand in action of dower, if any land is put therein, which is not in the tenure of the defendant; for, on a plea of non tenure in abatement of the writ, the plaintiff may leave out the lands, and pray that the tenant may anſwer to the remainder. The reaſon is, that theſe writs run in general, and therefore ſhall be good for the reſt. Act paſſed for this practice, 21 Hen. VIII. c. 3.

ABRINUNCIATION, or Abrenunciation, the act of renouncing. See Renunciation.

ABRODIETICAL, nice, or delicate diet.

ABROCHMENT, or Abbrochment, *Abrocamentum*, anciently denoted the engroſſing or buying up commodities by wholeſale, before they came to the public market, in order to ſell them off dear by retail, commonly called foreſtalling.

ABROGATION, from the Latin word *abrogo*, I repeal, ſignifies annulling, or making void; literally, repealing a law. Abrogation is ſynonymous with abolition and revocation.

ABROKANI, or Mallemolli, the name of a kind of muſlin, or clear white fine cotton cloth, brought from the Eaſt Indies, about 20 yards in length, and one in breadth.

ABROKUS, in botany, the name of a ſpecies of the bromus, or avena ſterilis, or wild goat; called by the Latins *orobus*, or *madida*; the Greeks βροχα. Virgil uſes the word for peaſe; Plautus, for all eſculent things that were boiled. Hence the baſtard peaſe and oats were called abrocha non madida, i. e. not fit for boiling or eating.

ABROLKOS, the name of certain ſhelves or banks of ſand, about 20 leagues from the coaſt of Brazil.

ABRONO, in botany, implies an herb, called heartpeaſe.

ABROTANUM, in botany, a ſynonime of ſeveral plants, commonly ſignifies ſouthern-wood. See Syſtem of Botany.

ABRUGI, in botany, the ſame as Abrono.

ABRUS, in the materia medica, the name of a ſeed produced by one of the phraſeole, or kidney beans, and uſually termed angola ſeed.

ABSCEDENTIA, in ſurgery, a term applied to decayed parts of the body, which, in a morbid ſtate, are ſeparated from the ſound, or loſe that union which was preſerved in a natural ſtate.

ABSCESS, in ſurgery, from *abſcedo*, to depart, a cavity containing pus, or gathering of matter in a part, ſo called, becauſe the parts which were joined are now ſeparated; one part recedes from another, to make way for the collected matter.

Abscess, is ſynonymous with apoſtem, apoſtema, impoſthume, and impoſthumation, which generally imply a tumor or inflammation.

An abſceſs, according to Mr. Bell's definition, is, an inflammatory tumor, containing a collection of purulent matter, confined in a fleſhy membrane, and may be frequently diſcuſſed before the abſceſs is formed (i. e. when the inflammation appears) by the application of proper medicines. But when it increaſes, and is attended with great pain, heat, and pulſation; when the fever perſiſts obſtinately, and theſe ſymptoms continue for three days, notwithſtanding all endeavours for a reſolution, that intention is to be entirely laid aſide; becauſe, if ſuch applications, as are proper to reſolve a humor, are continued, when reſolution is no longer poſſible, the moſt fluid parts of the obſtructing humours will be diſſipated, and the more groſs and inactive particles dried and hardened, ſo as to prevent ſuppuration, or at leaſt to render it difficult; in conſequence of which, a troubleſome induration of the part will remain, or, if glandulous, a ſchirrus will be formed. Very different methods, therefore, ſhould be uſed, and the humour brought to maturation with the utmoſt expedition. The proper medicines for promoting this intention are ſuch as increaſe the motion in the part, and have the tendency to excite a gentle fever; as fomentations and ſtimulating medicines. Such compoſitions alſo as confine the heat exerted in the part affected, by preventing an exceſſive perſpiration, are alſo proper. The ſimple arometic gums, and the emolient relaxing and moiſtening medicines, are therefore proper for maturating the pus. This method muſt be purſued till the abſceſs has acquired a ſufficient degree of ripeneſs, which may be known by the ſoftneſs of the part, and the fluctuation of matter in the tumor when preſſed, its whiteneſs and remiſſion of pain, heat, redneſs, tenſion, pulſation and fever; the pointed aſpect of the tumor, and a ſenſation of weight, ſucceeding the pain, are alſo ſigns that the pus is ſufficiently formed and fit for evacuation. When theſe ſigns indicate the maturity of the tumor, the knife is to be introduced into its ſofteſt, whiteſt, and moſt prominent part, till the pus flowing out, evinces that a ſufficient penetration is made; then let the knife be raiſed equally upwards, ſo as to make an inciſion ſufficiently large, or forcing its point through the oppoſite part of the abſceſs; let the intermediate integuments be divided, taking care to avoid the nerves and large veſſels. The inciſion being made and the pus evacuated, let the abſceſs be cured by cleanſing, ſuppurating, digeſtive, and deterſive medicines, which muſt be varied according to the ſtate of the part. If the patient be afraid of an inciſion, the abſceſs muſt be opened by a cauſtic: in order to which, the tumor muſt be covered with a plaiſter, in the middle of which is left an orifice of ſuch a ſize as may be judged moſt convenient, and in which a proper potential cautery muſt be applied to the ſkin; if the cauſtic be ſolid, it muſt be wetted before it is applied; the whole is then to be covered with another plaiſter, with compreſſes, and a proper bandage. In about five or ſix hours, or according to the ſtrength of the cauſtic, the eſchar will be formed, when the dreſſings muſt be taken off, and the eſchar divided from one end to the other with a biſtoury; in doing of which, care muſt be taken to go down as low as the pus. After the operation, the wound is dreſſed with digeſtives, and the eſchar will ſeparate in a few days with a plentiful ſuppuration. The management afterwards is the ſame as if opened by inciſion. See Syſtem of Surgery.

Abscess, in farriery, is a purulent tumor, incident to ſeveral animals, as horſes, ſheep, poultry, &c. See Syſtem of Farr ery.

ABSCISS, or Absis, in aſtronomy. See Apsis.

ABSCISSE, in conics, often called abſciſſa, implies a part of the diameter or tranſverſe axis of a conic ſection, intercepted between the vertex, or ſome other fixed point, and a ſemiordinate. See Conic Sections.

In the parabola, the abſciſſe is a third proportional to the parameter and the ordinate. In the ellipſis, the ſquare of the ordinate is equal to the rectangle under the parameter and abſciſſa, leſſened by another rectangle under the ſaid abſciſſa, and fourth proportional to the axis, the parameter and the abſciſſa. In the hyperbola, the ſquares of the ordinates are as the rectangles of the abſciſſa by another line, compounded of the abſciſſa and the tranſverſe axis. However, it is to be remarked, that the two propoſitions relating to the ellipſis and hyperbola, the origin of the abſciſſes, or abſciſſas, the point from whence they are reckoned, is ſuppoſed to be the vertex of the curve, or, which is the ſame, the point where the axis meets it: for, if reckoned from the center, the foregoing propoſitions will be erroneous, a principal matter which mathematicians ſhould guard againſt.

In mechanical curves there are no abſciſſes, unleſs the curved lines may be ſo called, as in the common cycloid, the arches of the generating circle, taken from the vertex of the figure, when the generating circle is in ſuch a ſituation as to have the abſciſſe coincide with the diameter.

ABSCISSION, from *abſciſſio*, in rhetoric, a figure of ſpeech, whereby the ſpeaker ſtops ſhort in the middle of his diſcourſe: ſo that an auditor is left to form his own conſtruction, or make what inference he pleaſes: e. g. "one of her ſex, age, and beauty, to be ſeen at ſuch an hour, with a man of his character! I ſhall ſay no more."

Abscission is a ſpecies of ellipſis or ſuppreſſion. It is held a deterioration.

Abscission, in ſurgery, is ſometimes uſed for amputation, but more properly for cutting off ſome part of the body, when become anywiſe hurtful: thus we ſay, the abſciſſion of the præpice, &c. In this ſenſe, it is the ſame with αποκοπη. Cowper uſes the word as ſynonimous with amputation. The Cyclopædia diſagrees with him. Bell's Syſtem upon Cheſſelden's plan agrees with Cowper. The Encyclopædia, publiſhed in Scotland, takes no notice of the word. In Phil. Tranſ. No. 283, Mr. Shipton ſpeaks of an abſciſſion of part of the inteſtines without danger.

Abscission, in the moſt unlimited ſenſe, when applied to ſurgical operations, ſignifies the dividing any corrupted and uſeleſs part of the body from that which is ſound, by means of ſome ſharp inſtrument.

ABSCONSA, a dark lanthern, uſed by the monks as a ceremonial, at the time of burying a deceaſed member.

ABSENCE, being from the uſual place of reſidence.

ABSENT, in law, implies in a general ſenſe, a perſon gone away from his habitation, with an intent to evade or avoid ſome conſequence appertaining to the eſtabliſhed laws of the realm.

ABSINTHITES, **Absinthiac**, or **Absinthiated**, a thing impregnated with wormwood, or abſinthium. In Act. Med. tom. 3. M. Bartholin mentions a woman whoſe milk became as bitter as gall, by the too frequent uſe of wormwood. Ray, Fehr, Paulli, and Dr. Bowle, have given treatiſes on it. Wormwood, in the opinion of the late celebrated Dr. Hunter, is a bitter as much wanting to Engliſh palates as tobacco: the latter of which he held in abhorrence, although he uſed ſnuff himſelf!

ABSINTHIUM, or **Wormwood**. See Artemisia.

Wormwood is greatly commended by many eminent phyſicians for its medicinal virtues, as a ſtrengthener of the ſtomach, and to remove obſtructions of the liver and ſpleen, creating an appetite, and deſtroying worms.

ABSOLUTE, in a general ſenſe, denotes ſomething which is unconnected with, or independent on any other thing.

Absolute is alſo applied to things which are free from limitation or condition: as abſolute, unreſtrained, power, decree, promiſe, &c. Hence, the covenant with Noah was abſolute, and without conditions; the Goſpel covenant was abſolute alſo, conditional, by faith and obedience, to avoid the penalty of God's wrath. In various notions of religion, the conditions are abſolute; thus, the Antinomians aſſert, that the goſpel covenant is abſolute, and that Chriſt has purchaſed our ſalvation, without any conditions to be performed on our part; but charity and the true light of God's word are not to be found among ſuch people, for the love of God and love of the world never abide together.

Absolute ſtands for independence, and relative for dependence; conſequently the Deity only is abſolute, and all things that are created muſt be dependent.

Absolute alſo denotes a thing's being free from conditions or limitations; in which ſenſe, the word is ſynonymous with unconditional. We ſay, an abſolute decree, abſolute promiſe, abſolute obedience.

Absolute *Government*, that wherein the prince is left ſolely to his own will, being not limited to the obſervance of any laws except thoſe of his own diſcretion.

Absolute *Gravity*, in philoſophy, is the whole force by which a body, ſhell, or ſhot, is impelled towards the centre.

Absolute *Number*, in algebra, is the known quantity which poſſeſſes entirely one ſide of the equation. Thus in the equation $xx+10x=64$, the number 64 poſſeſſing entirely one ſide of the equation, is called the abſolute number, and is equal to the ſquare of the unknown root x, added to $10x$, or to 10 times x.

Absolute *Equation*, in aſtronomy, implies the aggregate, or ſum of the optic and eccentric equations.

The optic equation ariſes from the apparent inequality of a planet's motion, in not being equally diſtant from the earth at all times, and would ſubſiſt even if the planet's real motion was uniform.

The eccentric equation ariſes from a planet's revolution round the ſun in an elliptical orbit, and being placed in one of the foci, deſcribes equal aræs in equal times: but, as the motion cannot be equal in all parts of the orbit, it occaſions the equation.

ABSOLUTELY, in a general ſenſe, ſtands oppoſed to relatively, i. e. when the terms of a propoſition are without relation to each other.

Absolutely, is alſo uſed for poſitively, or, unconditionally. Thus, the church of Rome aſſumes a poſitive or abſolute claim to forgive ſins, upon a full and open confeſſion. The church of England, in a milder ſenſe, receives this tenet declaratively; or, in other words, agreeably to the doctrine of the primitive church, which aſſumed no other authority than that delivered in the holy Scriptures.

Absolutely, in grammar, ſignifies a word, or phraſe, without government. Thus in the phraſe, 'We ſhould pray without ceaſing.' The word pray is taken abſolutely, as it governs nothing.

Absolutely, in geometry, ſignifies entirely, or completely. As a globe is abſolutely or entirely round, in contradiſtinction to that which is but partly ſo, as a cycloid, ſpheroid, &c.

ABSOLUTION, *abſolutio*, in civil law, is a ſentence whereby the party accuſed, is declared innocent of the crime laid to his or her charge.

The Roman law, thus defines it: after the cauſe had been pleaded by both parties, the prætor pronounced the word *dixerunt*, q. d. the parties have ſaid every thing they think neceſſary, and three billets, or ballots, were immediately given to each judge, one marked with A. for *abſolvo*, another with C. for *condemno*, and a third with N. L. for *non liquet*, and accordingly as there was a majority of billets, or ballots, the criminal was abſolved, condemned, or reſpited. See the Article A, a Roman abbreviation.

Absolution, in the canon law, is a juridical act, by which the prieſt declares the ſins of ſuch as are penitent remitted. In the church of Rome, the council of Trent, ſeſſ. xiv. cap. 3. declare the form or eſſence of the ſacrament to lie in the words of abſolution. I abſolve thee of thy ſins.

The formula of abſolution, in the Romiſh church, is abſolute; in the Greek church it is deprecatory, and in the churches of the reformed, declarative.

Absolution, in the latter caſe, is underſtood in the practice of the eccleſiaſtical courts in England, whereby a perſon who ſtands excommunicated is releaſed, or freed from that puniſhment, when error is found in the pleadings and proceedings of the court. Vide Stat. 23 Eliz.

ABSOLUTISM, the dogma of God's acting abſolutely in the affair of ſalvation. This doctrine is maintained by the calviniſts, for which bigotted tenet the Lutherans refuſe all union with them.

ABSORBENTS, generally imply ſuch things as have the faculty of abſorbing, or ſoaking up others. Ariſtotle ſays, a pot full of aſhes will abſorb as much water as if it was empty and filled with that liquid; but this received maxim, as well as many others of that celebrated philoſopher, is found to be falſe.

Absorbents, in medicine, are ſuch remedies as have the power of drying up redundant humours, whether applied externally or internally. In the Pharmacopæias there are ſeveral forms of abſorbents: ſuch as the teſtacious powders, boles, chalk, calcined bones, hartſhorn, crabs-eyes and claws, burnt ivory, terra ſagillata, and even iron itſelf. Alſo divers woods, as ſaſſafras, maſtic, ſanders, guaiacum, and divers roots, as ſarſaparilla, china, &c. Theſe powerful abſorbents, are chiefly given in diſorders ariſing from too great an abundance of acids in the ſtomach. It is a neceſſary precaution to drink diluting liquors along with abſorbents, alſo to take gentle purges, as well during the uſe of them, as when they are left off.

Absorbents, ſays Juncker, conſume the humours without fuſing them, and have ſometimes the effect of ſtrengtheners, ſometimes of purgatives, and oftener of calmers, to allay fermentations. They are of uſe for tempering acrimonies, and after emollients and attenuants, for healing tumors; ſome hold them neceſſary for preventing the ill effects of bitters: they are good in cardialgias, or heats of the ſtomach and hiccoughs; they are alſo given in hectics, and other chronical caſes; but, nevertheleſs, ſhould be uſed with great caution and reſerve. For, on being too laviſhly adminiſtered, congeſtions in the viſcera are frequently the conſequences. In the itch, bilious fevers, dyſenteries, hypochondrical and hyſteric caſes, they are extremely pernicious, and often fatal.

Many preſcribe them as ſalutary in removing infantile acute diſeaſes; but, it is certain, they are hurtful, in loading the tender viſcera of children, and creating obſtructions in the capillaries.

As to the ſeveral ſorts of abſorbents, generally in uſe, ſee the Syſtem of Pharmacy. And for their ſeveral applications, ſee the Syſtems of Medicine and Surgery.

The immoderate uſe of certain abſorbents has been attended with fatal conſequences. Vide Phil. Tranſ. N°. 459. ſect. 2.

Absorbent *Veſſels*, promiſcuouſly imply, the lacteal veſſels, lymphatics, and inhalent arteries, all of which imbibe the nutritious and other matters brought near them.

The abſorbent veſſels are ſometimes called reſorbent veſſels, and ſometimes abſorbent pores. Theſe are found in all parts of the body, eſpecially where the membranes lie open to cavities, as in the mouth, œſophagus, ſtomach, inteſtines, &c. A modern author computes many millions in every inch ſquare of the ſtomach; hence may be inferred, that the external application of mercurials to the ſtomach, enter the habit of the body inſtantaneouſly.

Mortimer aſſerts, that the pores of the human body imbibe the fluid matter, floating in the ambient air.

In the Medical Commentaries of the late Dr. Wm. Hunter, and in Dr. Garney's Obſervations on them, Medic. Muſ. vol. ii. p. 229, and alſo Dr. Wilkinſon, ibid. p. 117, ſome curious experiments and remarks, will be found well worth the attention of the learned in medical knowledge.

It is ſaid, that the more particular uſe of theſe veſſels, is to work upon the lacteals, which open into the ſides of the inteſtine tube to imbibe the chyle in its deſcent from the ſtomach, and convey it into the meſenteric veins: for their deſcription, ſee the Syſtem of Anatomy.

Many naturaliſts, particularly De la Hire, Malpighi, Leewenhoeck, and the immortal Linnæus, with ſeveral others, affirm the like abſorbents in plants; the fibrous or hairy roots of which are as a kind of *vaſa abſorbentia*, which attract and imbibe the nutritious juices from the earth. See the Syſtem of Botany for further illuſtration.

ABSORBING, the act of imbibing, or ſucking up any body, matter, or thing. Thus, black bodies, according to Sir Iſaac Newton, abſorb all the rays of light they receive. In this received opinion, M. Bouguer differs, as he aſſerts that the effect is to be attributed to the action of ſome power diffuſed over the black ſurface, and not to the impact of light on the ſolid parts of bodies. This he proves by ſeveral experiments. Vide his Traite d'Opique, Paris, 1787. A new edition.

It is ſaid, luxuriant branches abſorb or waſte the nutritious juices, which ſhould feed the principal ſtock plant of fruit, or other trees. P. Miller.

ABSORPTION, in the animal œconomy, ſignifies the act of imbibing; and, according to Dr. Monro, Med. Eſſ. Edin. vol. iii.

p. 132, the effect encreaſes, or diminiſhes, agreeably to the ſtrength or weakneſs of the animal body of a living creature.

Aqua vitæ, or any other ſtray fluid, applied to the ſurface of the ſkin, particularly the ſtomach, arm-pits, flanks, or hams, inſtantly draws in the ſpirit with the liquid through a ſet of pores appropriated for this action: which, beſide the property of capillary tubes, poſſeſs, likewiſe, a contractile power from irritation.

ABSORPTION *of the Earth*, a phraſe uſed by Kircher, and others, for the ſinking of large tracts of land, by means of ſubterranean commotions, uſually termed earthquakes.

Pliny relates, that in his time, the mountain Cymbotus, on the verge of which ſtood the populous town of Eurites, were wholly abſorbed into the earth, ſo that not a trace of either remained.

The city of Tantalis, in Magnaſia, the mountain Sypelus, the towns of Galanis and Garnatus, in Phœnicia, are recorded by the ſame author to have been abſorbed in like manner.

The vaſt promontary called Phlegium, in Ethiopia, after a violent earthquake in the night time, was inviſible the next morning. Kircher's Mand. Subter. p. 77.

The city of Liſbon, of a late date, has ſhewn an awful ſpectacle of this ſpecies of abſorption.

Added to theſe accounts, modern authors aſſert, that the mountain Picus, in one of the Molucca iſles, was ſo lofty, that it appeared at great diſtances as an immenſe column reared erect in the air, and ſerved as a land-mark to ſailors; an earthquake in this iſland deſtroyed it: at one inſtant the whole mountain was abſorbed into the bowels of the earth, and no mark of its place remained. A like accident, but of a more terrible kind, happened in China in the year 1556, when a whole province of the mountainous parts of that kingdom was in one moment abſorbed into the earth, and all the towns buried, the whole number of the inhabitants ſinking with it, and an immenſe lake of water remaining in its place to this time. Of much later date is the deſtruction of a city, in the confines of Swiſſerland: but this, though generally ſaid to have been ſwallowed up into the earth, was not properly an abſorption, for the whole city was buried by the fall of a mountain upon it.

The burning mountains, Veſuvius and Strongylus, both once very high, have in length of time loſt half their height, the upper part having been undermined by the burning, and having fallen into and been abſorbed by the underpart. And in the year 1646, during the terrible earthquake in the kingdom of Chili, ſeveral mountains in the Andes diſappeared, and were one after another wholly abſorbed in the earth.

Theſe, and a thouſand other accidents of the like kind, prove the truth of abſorptions in general; ſome of them leaving level ground in the place of the things abſorbed, ſome immenſe chaſms and cracks, and ſome lakes of freſh or ſalt water; and it may be that many immenſe lakes were formed in ages of which we have no hiſtory, by the like abſorptions.

Pliny gives many accounts of the reſtoring of places thus abſorbed; but later obſervations do not give an equal credit to thoſe parts of this hiſtory.

There are many inſtances, however, of iſlands being produced, though we cannot affirm them to have appeared in the place of any which have been abſorbed.

In the year 1638, an iſland was raiſed near St. Michael's, in the Atlantic ocean, by ſubterraneous fires, which threw up ſtones and other ſubterranean productions, in ſuch quantities, that they formed an iſland of five miles in length. The mountain raiſed in one night, in the ſea, near Puzzoli, is another inſtance of the ſudden production of theſe mountains: this appeared after one night's violent ſubterranean conflict, and ſtill keeps its place, and is known by the name of Mons Sanctus.

ABSTEMII, in church hiſtory, a name given to ſuch perſons as could not partake of the cup of the euchariſt, on account of their natural averſion to wine; Calviniſts allow theſe to communicate in the ſpecies of bread only, touching the cup with their lips; which on the other hand is, by the Lutherans, deemed a prophanation.

ABSTEMIOUS, is properly underſtood of a perſon who refrains abſolutely from all uſe of wine.

The hiſtory of Mr. Wood, in the Medic. Tranſ. vol. II. p. 261, art. 18, is a very remarkable exemplification of the very beneficial alterations which may be effected on the human body, by a ſtrict courſe of abſtemiouſneſs.

The Roman ladies, in the firſt ages of the republic, were all enjoined to be abſtemious; and that it might appear by their breath, whether or no they kept up the injunction, it was one of the laws of the Roman civility, that they ſhould kiſs their friends and relations whenever they accuſed them.

ABSTENTUS, among Civilians, is underſtood of an heir withheld by his tutor from taking on him an inheritance. Among eccleſiaſtical writers, the word is alſo uſed for a perſon excommunicated.

ABSTERGENTS, or **ABSTERSIVE MEDICINES**, more uſually called among phyſicians, detergents, are cleanſing medicines of a ſaponaceous nature, capable of diſſolving concretions formed of earth and oil, which water ſimply, as an abluent, cannot effect.

ABSTINENCE, in a general ſenſe, implies the act or habit of refraining from ſomething which we have a propenſity to, or find a pleaſure in. The word is derived from *abſtinere*, formed of *abs*, from, and *tenere*, to hold.

The Jewiſh law ordained that the prieſts ſhould abſtain from the uſe of wine, during all the time of their being employed in the ſervice of the temple. The ſame abſtinence was enjoined the Nazarites, during the time of their Nazariteſhip, or ſeparation. The Jews were commanded to abſtain from ſeveral ſorts of animals, viz. all ſuch as have not the hoof parted, and do not chew the cud. The fat of all ſorts of animals that were ſacrificed, was forbidden to be eaten, and the blood of every animal in general, was prohibited under pain of death. Neither did they eat the ſinew, which is upon the hollow of the thigh, though it be otherwiſe pure, becauſe the angel who wreſtled with Jacob at Mahaniam, touched the hollow of his thigh, which occaſioned the ſinew to ſhrink. They abſtained likewiſe from thoſe animals which had been taken by a devouring and impure beaſt, ſuch as a dog, a wolf, a boar, &c. and from ſuch as died of themſelves. Fiſh that have neither fins nor ſcales were to be abſtained from as impure.

Some are of opinion that this diſtinction of animals, into clean and unclean, was intended to denote the moral purity or impurity which the Hebrews were to endeavour after, or avoid. A hog, for inſtance, ſignifies gluttony; a hare, laſciviouſneſs; and ſo of others: again, a ſheep denotes gentleneſs; a pigeon, ſimplicity; and the like. But many commentators are of opinion, that ſeveral animals were declared unclean, and therefore to be abſtained from, only becauſe of ſome qualities in them naturally hurtful or pernicious to health.

Among the primitive Chriſtians, ſome denied themſelves the uſe of ſuch meats as were prohibited by the law; others looked upon this abſtinence with contempt.

St. Paul has given his opinion in this matter: 'One believeth that he may eat all things; another who is weak eateth herbs. Let not him that eateth deſpiſe him that eateth not. And let not him that eateth not, judge him that eateth.' Rom. xiv. 1, 2, 3, and 1 Cor. viii. 7 and 10. The council of Jeruſalem, which was held by the apoſtles, enjoined the Chriſtian converts to abſtain from meats ſtrangled, from blood, from fornication, and from idolatry.

Abſtinence, as preſcribed by the goſpel, is intended to mortify and reſtrain the paſſions, to humble our vicious natures, and by that means raiſe our minds to a due ſenſe of prayer and devotion.

But there is another ſort of abſtinence, which may be called ritaul, and conſiſts in abſtaining from particular meats at certain times and ſeaſons.

The Jews were obliged to abſtain from their wives at certain ſeaſons. The ſame is enjoined in the apoſtolical conſtitutions, on all faſts and meagre days; the church of England recommends certain days of faſting and abſtinence. Abſtinence from fleſh, has been enjoined by ſtatute ever ſince the Reformation, particularly on Fridays and Saturdays, and on the vigils, and all commonly called fiſh-days. Vide 2 and 3 Edw. VI. Cap. 19.

The like injunctions were renewed under Queen Elizabeth, but at the ſame time it was declared, that this was done not out of motives of religion, as if there were any difference in meats, but in favor of the conſumption of ſea fiſh, and to multiply the number of fiſhermen and mariners, as well as ſpare the flocks of ſheep. Vide 5 Eliz. chap. 15. The great faſt, ſays St. Auguſtin, is to abſtain from ſin.

The ancient Athletæ lived in perpetual abſtinence from all kind of ſenſible pleaſure, to render their bodies more robuſt and hardy.

Several writers are of opinion, that before the flood, mankind abſtained from wine and fleſh, becauſe the Scriptures expreſly mention, that Noah, immediately after the deluge, began to plant the vine, and that God permitted him to make uſe of animal food; whereas he had given to Adam nothing more than the fruits and plants of the earth. This opinion, however, is not univerſal; many learned interpreters maintain the contrary, and believe that mankind before the deluge did not deny themſelves the pleaſures of either wine, or animal food.

The Phœnicians and Aſſyrians, who were neighbours to the Jews, had their ſacred faſts. The Egyptians, according to Herodotus, ſacrificed a cow to Iſis, after they had prepared themſelves by faſting: he alſo attributes the ſame cuſtom to the women of Cyrene. Among the Athenians, the Eleuſinian feaſts, as well as the Thermophores, were attended with rigorous faſtings, eſpecially among the women, who paſſed a whole day ſitting on the ground in a mourning habit, and without taking the leaſt ſuſtenance. The Romans had alſo ſettled faſts in honor of Jupiter. Hiſtorians alſo mention thoſe of Julius Cæſar, Auguſtus, Veſpaſian, Marcus Aurelius, &c. The Pythagoreans, at leaſt thoſe among them who profeſſed the greateſt perfection, and gloried in having attained to the higheſt degree of their maſter's theory, never eat either fleſh or fiſh: their abſtaining from whatever had life, was a conſequence of the metempſychoſis; though it is not eaſy to diſcover the cauſe from whence Pythagoras imbibed that averſion he always had to beans, mallows, wine, &c. He might, indeed, abſtain from eggs, becauſe chickens were produced from them; but upon what foundation could he build his argument, that the bean was a ſacred plant? His opinion that the gods patronized it, could flow only from ſuperſtition: and his belief that the mallow had any qualities repugnant to health, could only be the effect of ignorance, or at leaſt the want of experience.

In the brute creation we ſee extraordinary inſtances of long abſtinence, many of the ſpecies paſs four, five, or ſix months, every year, without either food or water. The ſerpent, land tortoiſe, dormouſe, &c. are obſerved to retire regularly, at certain ſeaſons, to their reſpective cells, and conceal themſelves from ſight; ſome hide themſelves in the caverns of rocks, or ruins; ſome dig holes in the earth; while others retire to the woods, and lay themſelves up in the clefts of trees.

Several ſpecies of birds, and almoſt the whole tribe of inſects, are capable of ſubſiſting the whole winter, not only without food, but even without reſpiration. This particular furniſhes us with an admirable inſtance of the wiſdom of the Creator: the proper food of theſe creatures, particularly thoſe of the inſect tribe, being then wanting, proviſion is made for them to live without it. When the fields are diveſted of their flowery furniture, and the trees and plants are ſtripped of their fruits, what would become of creatures ſubſiſting only by the produce of the ſpring and ſummer? And when the air is grown rigid and chilled with froſt, what could ſupport theſe tender ſpecies which are impatient of cold? Therefore to prevent the total deſtruction and extirpation of ſo many ſpecies of animals, the author of nature has wiſely provided, that creatures thus bereaved of their food, ſhould be alſo impatient of cold, in order to lead them to ſome receſs, where they may find ſhelter from danger; while the natural texture and vicidity of their blood, diſpoſes it, by a farther degree of cold, to become almoſt ſtagnant in their veſſels; ſo that the circulation being hardly carried on, and the animal function in a great meaſure ſuſpended, there is no ſenſible waſte or conſumption of parts, but they remain in a drowſy neutral ſtate between life and death, till the warm ſun at once recalls them to life, and produces the food neceſſary to their exiſtence by thawing the congealed juices both of theſe animals and vegetables. Hence it is no wonder that land tortoiſes, dormice, &c. are found as fat and fleſhy after ſome months abſtinence as before. Sir George Ent, tells us, Phil. Tranſ. No. 194, that he weighed his tortoiſe ſeveral years ſucceſſively, at its going into the earth in October, and at its coming out again, in March; and found that of 4℔ 4 oz. it never loſt more than an ounce.

We have alſo inſtances of men paſſing ſeveral months in abſtinence, like other creatures. The records of the tower mention a Scotchman impriſoned for felony, and carefully watched in that fortreſs for ſix weeks, during which time he took not the leaſt ſuſtenance, and for this peculiarity received his pardon.

It is to be added, that, in moſt inſtances of extraordinary human abſtinence, related by naturaliſts, there were ſaid to have been apparent marks of a texture of blood and humours much like that of the animals abovementioned; though it is no improbable opinion, that the air itſelf may furniſh ſomething for nutrition. It is certain there are ſubſtances of all kinds, animals, vegetables, &c. floating in the atmoſphere, which muſt be continually taken in by reſpiration; and that an animal body may be nouriſhed thereby, is evident in the inſtance of vipers; which if taken, when firſt brought forth, and kept from every thing but air, will grow very conſiderably in a few days. So the eggs of lizards are obſerved to increaſe in bulk, after they are produced, though there be nothing to furniſh the increment but air alone; in like manner, as the eggs or ſpawn of fiſhes grow, and are nouriſhed with the water.

ABSTINENCE, in phyſic, is a term of very extenſive ſignification; for it implies, a privation of all ſucculent aliments. Though abſtinence is not ſufficient for the cure of diſeaſes, yet it greatly aſſiſts the operation of medicines, and is a preventative againſt a multitude of dangerous diſorders. Several writers relate extraordinary cures performed by it, and in protracting the term of human life. The noble Venetian, Conaro, after every method had been tried in vain, and his life was deſpaired of, when he was no more than forty years of age, recovered his former health, and lived to be near an hundred years old; by the ſole effect of abſtinence, as he himſelf tells us in a book he publiſhed on that ſubject. It is indeed ſurprizing to what a great age the primitive Chriſtians of the Eaſt, who retired from perſecution into the deſerts of Arabia and Egypt, lived, healthful and cheerful, on a very little food. Caſſian aſſures us, that the common allowance for twenty-four hours was only twelve ounces of bread and mere water. He adds, that, with this ſparing diet, St. Anthony lived an hundred and five years; James, the hermit, one hundred and four; Arſenius, tutor to the Emperor Arcadius, an hundred and twenty; St. Epiphanius, an hundred and fifteen; Simeon, the Stylite, an hundred and twelve; and Romauld, an hundred and twenty. Nor need we have recourſe to the Eaſtern chriſtians, for examples, ſince the hiſtory of our own country furniſhes us with ſome, even ſuperior to thoſe already recited. Buchan relates that one Laurence preſerved his life to an hundred and forty years, by temperance and labour: and Spotſwood mentions one Kentigem, afterwards called St. Monga, or Mungo, who lived to the age of an hundred and eighty five, by the ſame means.

Dr. Cheyne imputes moſt of the chronical diſeaſes, the infirmities of old age, and the ſhort lives of Engliſhmen, to repletion; and may be either prevented or cured by abſtinence.

ABSTINENCE is alſo uſed ſometimes to ſignify a ſuppreſſion. Thus in Cœlis Aurelianus, *abſtinentia ſudoris*, ſignifies a ſuppreſſion of ſweat. Sometimes in this author it means a compreſſion; as *ſpiritus ab abſtinentiam clauſus*, means the wind ſhut up in the inteſtines by compreſſion, thereby cauſing the Iliac paſſion.

ABSTINENTS, or ABSTINENTES, a ſet of heretics, that appeared in France and Spain, about the end of the third century. They are ſuppoſed to have borrowed part of their opinions from the Gnoſtics and Manicheans, becauſe they oppoſed marriage, condemning the uſe of fleſh meat, and placed the Holy Ghoſt in the claſs of created beings. We have, however, no certain account of their peculiar tenets. In eccleſiaſtical hiſtory, ſome authors repreſent the Abſtinentes, as the ſame with thoſe otherwiſe called Continentes, and that they particularly enjoined abſtinence from the uſe of marriage. Some make them the ſame with the Hierarcites; others with the Encratites.

ABSTRACT, *Abſtractum*, in a general ſenſe, any thing ſeparated from ſomething elſe, which is of like parts, powers, or principles.

ABSTRACT *Idea*, in metaphyſics, is a partial idea of a complex object, limited to one or more of the component parts, or properties; laying aſide, or abſtracting from the reſt. Thus in viewing an object with the eye, or recollecting it in the mind, we can eaſily abſtract from ſome of its parts or properties, and attach ourſelves to others: e. g. We can attend to beautiful hues of fruits or flowers, without paying any regard to their figure, ſhape, taſte, ſmell, or conſiſtence.

ABSTRACT *Terms*, in logic, are ſuch as denote thoſe objects which exiſt in imagination only. Thus beauty and uglineſs are abſtract terms. There are ſome objects that pleaſe and appear beautiful; others affect us in a very different manner, which we call ugly; and yet there are no ſuch real ſubſtances in nature, as beauty or uglineſs; they ſubſiſt only in our imagination.

ABSTRACT is alſo extended to divers other things, in reſpect of their purity, ſimplicity, ſubtilty, &c.

ABSTRACT *Numbers*, are aſſemblages of units, conſidered in themſelves, and not applied to denote any collections of particular and determined things. Thus, 5 is an abſtract number, if conſidered ſimply by itſelf: but, if we ſay 5 pounds, 5 miles, &c. then the 5 becomes a concrete number.

ABSTRACT *Mathematics*, otherwiſe called *pure mathematics*, are thoſe branches which treat of magnitude or quantity, conſidered abſolutely, without any reſtriction to a particular part. Thus, geometry, algebra, and arithmetic, are abſtract mathematics. In this ſenſe, abſtract mathematics ſtand oppoſed to mixed mathematics; wherein, ſimple and abſtract properties, and the relations of quantities, primitively conſidered in pure mathematics, are applied to ſenſible objects, and by that means become intermixed with phyſical conſiderations; ſuch are, *Navigation*, *Hydroſtatics*, *Optics*, *&c.*

ABSTRACT, in literature, a compendious view of any large work, being ſynonymous with *abridgment*, a term ſignifying the reduction of a book into a ſmaller compaſs.

The art of conveying much ſentiment in few words, is the happieſt talent an author can be poſſeſſed of. This talent is peculiarly neceſſary in the preſent ſtate of literature; for many writers have acquired the dexterity of ſpreading a few critical thoughts over ſeveral hundred pages. When an author hits upon a thought that pleaſes him, he is apt to dwell upon it, to view it in different lights, to force it in improperly, or upon the ſlighteſt relations. Though this may be pleaſant to the writers, it tires and vexes the reader. There is another great ſource of diffuſion in compoſition. It is a capital object with an author, whatever be the ſubject, to give vent to all his beſt thoughts. When he finds a proper place for any of them, he is peculiarly happy. But, rather than ſacrifice a thought he is fond of, he forces it in by way of digreſſion, or ſuperfluous illuſtration. If none of theſe expedients anſwer his purpoſe, he has recourſe to the margin, a very convenient apartment for all manner of pedantry and impertinence. There is not an author, however correct, but is more or leſs faulty in this reſpect. An *abridger*, however, is not ſubject to theſe temptations. The thoughts are not his own; he views them in a cooler and leſs affectionate manner; he diſcovers an impropriety in ſome, a vanity in others, and a want of utility in many. His buſineſs, therefore, is to retrench ſuperfluities, digreſſions, quotations, pedantry, &c. and to lay before the public only what is really uſeful. This is by no means an eaſy employment: to abridge ſome books, requires talents equal, if not ſuperior, to thoſe of the author. The facts, manner, ſpirit, and reaſoning, muſt be preſerved; nothing eſſential, either in argument or illuſtration, ought to be omitted.

Theſe obſervations relate ſolely to ſuch abridgments as are deſigned for the public; but when a perſon wants to ſet down the ſubſtance of any book, a ſhorter and leſs laborious method may be followed. It would be foreign to our plan to give examples of abridgements for the public: but as it may be uſeful, eſpecially to young people, to know how to abridge books for their own uſe, after giving a few directions, we ſhall exhibit an example or two, to ſhew with what eaſe it may be done.

Read the book carefully; endeavour to learn the principal view of the author; attend to the arguments employed: when you have done ſo, you will generally find, that what the author uſes as new or additional arguments, are in reality only collateral ones, or extenſions of the principal argument. Take a piece of paper or a common-place book; put down what the author wants to prove, ſubjoin the argument or arguments, and you have the ſubſtance of the book in a few lines. For example,

In the Eſſay on Miracles, Mr. Hume's deſign is to prove, That miracles which have not been the immediate objects of our ſenſes, cannot reaſonably be believed upon the teſtimony of others.

Now, his argument (for there happens to be but one) is,

"That experience, which in ſome things is variable, in others uniform, is our *only* guide in reaſoning concerning matters of fact. A variable experience gives riſe to probability only; an uniform experience amounts to a proof. Our belief of any fact from the teſtimony of eye-witneſſes is derived from no other principle than our experience in the veracity of human teſtimony. If the fact atteſted be miraculous, here ariſes a conteſt of two oppoſite experiences, or proof againſt proof. Now, a miracle is a violation of the laws of nature; and as a firm and unalterable experience has eſtabliſhed theſe laws, the proof againſt a miracle, from the very nature of the fact, is as complete as any argument from experience can poſſibly be imagined; and if ſo, it is an undeniable conſequence, that it cannot be ſurmounted by any proof whatever derived from human teſtimony."

In Dr. Campbell's Diſſertation on Miracles, the author's principal aim is to ſhew the fallacy of Mr. Hume's argument; which he has done moſt ſucceſsfully by another ſingle argument.

"The evidence ariſing from human teſtimony is not ſolely derived from experience: on the contrary, teſtimony hath a natural influence on belief antecedent to experience. The early and unlimited aſſent given to teſtimony by children gradually contracts as they advance in life: it is, therefore, more conſonant to truth, to ſay, that our diffidence in teſtimony is the reſult of experience, than that our faith in it has this foundation. Beſides, the uniformity of experience, in favour of any fact, is not a proof againſt its being reverſed in a particular inſtance. The evidence ariſing from the ſingle teſtimony of a man of known veracity will go farther to eſtabliſh a belief of its being actually reverſed: if his teſtimony be confirmed by a few others of the ſame character, we cannot withhold our aſſent to the truth of it. Now, though the operations of nature are governed by uniform laws, and though we have not the teſtimony of our ſenſes in favour of any violation of them; ſtill, if in particular inſtances we have the teſtimony of thouſands of our fellow-creatures, and thoſe too men of ſtrict integrity, ſwayed by no motives of ambition or intereſt, and governed by the principles of common ſenſe, that they were actually eye-witneſſes of theſe violations, the conſtitution of our nature obliges us to believe them."

Theſe two examples contain the ſubſtance of about 400 pages. Abridgments have many advantages; it engages us to read with accuracy and attention; it fixes the ſubject in our minds; and, if we ſhould happen to forget, inſtead of reading the books again, by glancing a few lines, we are not only in poſſeſſion of the chief arguments, but recal in a good meaſure the author's method and manner.

Abridging is peculiarly uſeful in taking the ſubſtance of what is delivered by profeſſors, &c. It is impoſſible, even with the aſſiſtance of ſhort-hand, to take down, verbatim, what is ſaid by a public ſpeaker. Beſides, although it were practicable, ſuch a talent would be of little uſe. Every public ſpeaker has circumlocutions, redundancies, lumber, which deſerve not to be copied. All that is really uſeful may be comprehended in a ſhort compaſs. If the plan of the diſcourſe, and arguments employed in ſupport of the different branches, be taken down, you have the whole. Theſe you may afterwards extend in the form of a diſcourſe dreſſed in your own language. This would not only be a more rational employment, but would likewiſe be an excellent method of improving young men in compoſition; an object too little attended to in all univerſities.

ABSTRACTI, *abſtracted*, in eccleſiaſtical hiſtory, a ſect of Lutherans, who followed biſhop Heſhuſius of Berlin, in Pruſſia, who aſſerted againſt Beza "That Chriſt was to be adored, not only in the concrete, as the ſon of God, but that his fleſh, in the abſtract, was an object of adoration." Wigandus prevailed ſo far againſt Heſhuſius, as to get him depoſed; afterwards, the abſtracti gained the aſcendant, and Wigandus was ſilenced. Micræl. Hiſt. Eccl. l. 3. ſ. 2. &c. Budd. Iſag. Hiſt. Theol. l. 2. c. 7.

ABSTRACTION, in general, the act of abſtracting, or the ſtate of being abſtracted.

Abstraction, in metaphyſics, the operation of the mind when occupied by abſtract ideas. A large oak fixes our attention, and abſtracts us from the ſhrubs that ſurround it. In the ſame manner, a beautiful woman in a crowd, abſtracts our thoughts, and engroſſes our attention ſolely to herſelf. Theſe are examples of real abſtraction: when theſe, or any others of a ſimilar kind, are recalled to the mind after the objects themſelves are removed from our ſight, they form what is called abſtract ideas, or the mind is ſaid to be employed in abſtract ideas. But the power of abſtraction is not confined to objects that are ſeparable in reality as well as mentally: the ſize, the figure, the colour of a tree are inſeparably connected, and cannot exiſt independent of each other: and yet we can mentally confine our obſervations to any one of theſe properties, neglecting or abſtracting from the reſt.

It is the faculty or power of abſtracting, that makes the great difference between man, and the brute creation; they ſeem to reaſon about particular objects and ideas, but there appear in them no traces of abſtraction, or forming general ideas.

Dr. Price, in his Review of the Principal Queſtions and Difficulties in Morals, p. 43. Dr. Cudworth, in his Eternal and Immutable Morality, book 4. Dr. Campbell, in his Philoſophy of Rhetoric, vol. 2, p. 105, as well as Mr. Locke, and Dr. Berkley, have ſeverally given a very accurate deſcription of *abſtraction*, both generally and particularly. We might add two celebrated writers on the theory of moral philoſophy, namely, Lord Bolingbroke, and Hume, who have defined this extenſive word for generalizing: but, as their works are tainted with dangerous tenets, it would be better that their labours were forgotten; therefore, we wiſh to guard every claſs of readers, againſt ſuch pernicious compoſitions, as the metaphyſical productions of theſe authors are.

Doctors Reid, Beattie, and Oſwald, have wrote in this wide field of philoſophy, and have been well received by the public; but, in our opinion, Paley's Moral and Political Philoſophy, notwithſtanding it is not wholly freed from error, is ſuperior to any of thoſe modern founders of morality.

We ſhall only add, that abſtracting, on the common ſyſtem, is no more than generalizing: it is making one thing ſtand for a hundred, by omitting the conſideration of the differences between them: it is taking ſeveral differents, i. e. different combinations, ſetting aſide the peculiarities in each, and conſidering only what is found alike in all. Thus it is that I ſay, I love my friend, love my miſtreſs, love myſelf, my bottle, my book, my eaſe, &c.

ABSTRACTITIOUS, or Abstractive, is applied, by modern chemiſts, to a ſpirit drawn from vegetables, without fermentation: in which ſenſe, abſtractitious ſpirits are ſynonimous with natural ſpirits, and ſtand oppoſed to fermentative, or artificial ones. Such ſpirits are chiefly procured from plants, which abound in volatile ſalt. The abſtractitious ſpirit of ſcurvy graſs, is preferred by fermentation. All the native ſpirits of aromatic plants, are called abſtractitious.

ABSTRUSE, a term denoting ſomething that is difficult, dark, obſcure, and not eaſy to be underſtood. Thus, metaphyſics is an abſtruſe ſcience; as is the new doctrine of infinite ſeries, which very few thoroughly underſtand.

The word is derived from the Latin, *abſtruſus*, formed of, *abs*, from, and *trudo*, I thruſt.

ABSURD, an epithet given to any action, ſentiment, or thing, which contradicts, or runs counter to a manifeſt truth, or to the received opinions of mankind. Thus, it would be abſurd to affirm, that 4 times 5, are 19; or that 19s. is a pound ſterling.

Reductio ad ABSURDUM, or arguing *ex abſurdo*, in the ſciences of logic and mathematics, implies a method of proving the truth of a propoſition, by ſhewing it would be abſurd to deny it. Euclid, in his Elements of Geometry, Sir Iſacc Newton, in his Theory of the Solar Syſtem, and Dr. Watts, in his Logic, have had recourſe to this method of reaſoning.

When the term, *abſurd*, is applied to actions, it has the ſame import as *ridiculous*.

ABSURDITY, that error by which any thing may be denominated abſurd.

The doctrine of the modern ſect of Unitarians, is a great abſurdity, becauſe it is contrary to the Holy Scriptures, and the Chriſtian faith.

The doctrine of a vacuum is alſo an abſurdity, becauſe it is contrary to Ariſtotle; and that of a plenum, as being contrary to Sir Iſaac Newton.

> —— *Nihil tam abſurdè dici poteſt,*
> *quod non dictatur à philoſopho.* Cicero.

Hence it may be inferred, that of all ideal ſyſtems, that of philoſophy is moſt apt to err; the reaſon ſeems to be, that of all men, thoſe called philoſophers are the leaſt diſpoſed to give proofs that are capable of experiment; and, for the moſt part, content themſelves with an abſtruſe mode of reaſoning, neglecting to explain the terms they make uſe of; i. e. the preciſe idea each is made to repreſent; and, indeed, may well be compared to a man's undertaking to number, without knowing the value of the numeral figures.

ABSUS, the Egyptian lotus.

ABSYNTHIUM, or Absinthum. See Artemisia.

ABSYNTHUS, in natural hiſtory, the name of a ſtone, of a black colour, variegated with ſpots of red; and, when heated, retains its warmth for ſeven days.

ABTHANES, a title of honor, anciently conferred on the inhabitants of Scotland, who were ennobled, generally called, thanes, derived from the Saxon word, chancvy, or, king's miniſters, with this diſtinction, that the higher ranks were called, abthanes, and the lower ſubthanes, or underthanes.

ABUCCO, Abocco, or Abocchi, a weight uſed in the kingdom of Pegu, equal to 12½ teccalis : 2 abuccos = 1 agire : 2 agire = ½ hiza ; = 100 teccalis; i. e. 2℔. 5 oz. heavy, or 3℔. 9 oz. light weight of Venice.

ABUKESO, the Turkiſh name of the aſlani, or 115th part of an aſper.

ABUNA, which in the Abbyſine or Abyſſinian tongue, implies *our father*, a name given to the archbiſhop or metropolitan of Abyſſinia.

This patriarch, or pontiff, had formerly ſuch extenſive authority that the king himſelf was not acknowledged as duly eſtabliſhed on his throne, until he was firſt conſecrated by the hands of the *abuna*. But at preſent his power is conſiderably abridged.

The *abuna* is repreſented as a perfect ignoramus, and the prieſts he ordains are more illiterate than himſelf, and perſons of diſſolute lives. He is dependent on the patriarch of Alexandria, who conſtitutes and appoints ſuch perſon to be metropolitan of Abyſſinia as he thinks proper. And for this reaſon it is, that the Abyſſine prieſts mention in their prayers the patriarch of Alexandria before their own metropolitan, who, after his election, is accountable for his conduct, and the due adminiſtration of his office to that patriarch.

ABUNDANCE, Abundantia, in heathen mythology, an ideal deity who preſided over plenty, or the general produce of harveſt. In a modern acceptation of the word, it implies, to abound in ſuperfluous plenty, or more than is neceſſary.

ABUNDANT *Number*, in arithmetic, a number, whoſe aliquot parts, added together, exceed it : e. g. 12 is an abundant number, as its aliquot parts 1, 2, 3, 4, and 6, make 16 inſtead of 12.

Abundant *Number* is oppoſed to a deficient or defective number, both of which vary from a perfect number : e. g. 10, is a deficient number; its quota parts 1, 2, and 5, are but 8, inſtead of 10. But 6 is a perfect number, as its aliquot parts or ſubdiviſions 1, 2, and 3, make 6 exactly.

Abundant *Notion*, in logic, implies a thing which may be known by various marks or characters, their redundancy not being neceſſary, as fewer names would ſuffice. See Syſtem of Logic.

ABUSE, in a general ſenſe, the perverting ſomething from its true deſign, purpoſe, or intention. It is compounded of *ab*, from, and *uſus*, uſe. In grammar, the words abuſe, abuſive, or abuſively, imply the uſing words in ſo prepoſterous a manner that they convey no clear or diſtinct idea.

Words being the medium through which perſons communicate their diſcoveries, reaſonings, and knowledge to each other, he who uſes them improperly, though he does not corrupt the fountain of knowledge, which are in the things themſelves; yet he endeavours to deſtroy the effect by which they are diſtributed to mankind, and may therefore be conſidered as an enemy to the improvement of human learning.

A permutation of benefices, without the conſent of the biſhop, is deemed *abuſive*, and conſequently is null and void to all intents and purpoſes.

ABUTILON, in botany, the trivial name of ſeveral ſpecies of the *ſida*, as claſſed in Monadelphia. See Syſtem of Botany.

ABUTTALS, or Abbutals, in law, denote the mears, bounds, buttings, boundings, or boundaries of a piece of land; by which it is to be underſtood the ſeveral parts or particulars that lay around it, by a deſcriptive title alluding to the four cardinal points; hence, it is to be inferred, that all freehold, copyhold, or leaſehold premiſes, whether houſes or lands, ſhould have a full deſcription of the parcels, or particulars, either by a map or circumjacent abuttals, expreſſed in words at full length in the body of the deed. This matter properly attended to would, of courſe, prevent many chancery ſuits to aſcertain original boundaries, &c.

ABYSS, in a general ſenſe, denotes ſomething very deep, profound, and, as it were, bottomleſs. The word is originally Greek, *αϐυσσος*, compounded of the primitive *α*, and *βυσσος*, q. d. without a bottom.

Abyss, in a particular ſenſe, denotes that immenſe cave in the earth, into which it is ſuppoſed the Almighty, on the third day of the creation, collected all the waters, which before covered the ground, to ſerve as a reſervoir for the ſupply of his creatures.

The ideas of Dr. Woodward, quoted in almoſt every Dictionary that has been publiſhed of late years, betrays ſo whimſical a turn, that a ſerious reader muſt feel himſelf much hurt, upon the peruſal of ſuch imperfect reaſoning, all of which turns upon the fallacious hypotheſis, that man can ſcan the unſearchable wiſdom of God! Does not this way of defining the creation carry a palpable abſurdity on the face of it? We therefore explode every ſpecies of legendary information, which could ſerve no other intention than that of leading our readers into error, which we ſhall always carefully avoid.

Camerarius, Kempfer, Ray, Cockburn, Whitehurſt, Burnet, Whiſton, Bourguet, Scheuchzer, and many others, have given their thoughts freely on this ſubject; but as they are all but bare notions of men, and founded upon no certain ſtandard to obtain proofs by, we omit their ſeveral definitions, as inſufficient and unſatisfactory.

Abyss, in the Septuagint verſion of the Old Teſtament, implies a great deep; as in the old tranſlations, the word has been rendered, "and darkneſs was on the face of the abyſs," i. e. the *great deep* which the tranſlators of the Engliſh bible have rendered *deep* only.

Abyss is alſo uſed to denote hell, in which ſenſe the word is ſynonymous with *Barathrum*, *Erubus*, and *Tartarus*; in the Engliſh bible, the bottomleſs pit. *Cruden's Concordance.*

The unclean ſpirits expelled by Chriſt begged, according to the vulgate of the New Teſtament, and they beſought him, that he would not command them to go out into the *deep*, (*Abyſs.*) Luke viii. 31. vide Rev. ch. 9. v. 1. abyſs, or bottomleſs pit.

Abyss, in antiquity, is uſed to ſignify the Temple of Proſerpine, under ground, wherein was found an immenſe quantity of gold, ſilver, and precious ſtones.

Abyss, in heraldry, the centre of the eſchutcheon. In which ſenſe, a thing is ſaid to be bore in abyſs, *en abyſſme*, when placed in the middle of the ſhield, clear from any other bearing : he bears azure, a *fleur-de-lis*, in abyſs.

Abyss, among alchemiſts, is uſed by ſome for the immediate receptacle of the ſeminal matter, and by others for the firſt matter itſelf.

Abyss, in a metaphorical ſenſe, is applied to any thing that is inſcrutable, or incomprehenſible; thus, the judgment of God is called, a great *abyſs*.

Abyss, in hydography, the ſame as *gulph*.

ABYSSINIAN *Church*, that eſtabliſhed in the empire of Abyſſinia; it makes only a branch of the cophts or jacobites, a ſect of heretics, who reject the council of Chalcedon. From this doctrine they are alſo called Eutychians, and ſtand oppoſed to the Melchites.

The doctrines and ritual of this ſectary form a ſtrange compound of Judaiſm, Chriſtianity, and ſuperſtition. They practice circumciſion. They keep Saturday, the ſeventh day, and Sunday, the firſt day of the week, as Sabbaths; thereby attending to the Jewiſh, as well as Chriſtian Sabbath. They eat no meats prohibited by the law of Moſes, and in many reſpects attend to the cuſtoms enjoined by the Moſaical law. Like the Roman Catholics they pray for their dead, and invoke ſaints and angels, and pay extraordinary veneration to the Virgin Mary. Images in painting are allowed in their churches, ſome of which are highly extolled, but they abhor all thoſe in relievo, except the croſs.

The books called Apocryphal they hold as canonical, and admit legendary conſtitutions and canons of the apoſtles as genuine.

Alvarez and Pagit have given their liturgy, and Ludolf their calendar. As to their doctrine of the ſoul of man, it ſeems more rational than that advanced by Dr. Prieſtly, and a few other ſceptical writers : as the Abyſſinians ſay, that man's ſoul was not created, but proceeds from the earthly father, Adam, throughout all the generations of the world; alledging, that God finiſhed the work of creation on the ſixth day; and as he breathed into man the breath of life, conſequently man was capable of producing his own ſpecies, with both parts, ſoul and body, to the laſt of the world.

ACACALIS, in the materia medica, the name given by ſome authors to the ſiliqua ſylveſtris.

ACACALOTL, in ornithology, a name given to the Braſilian web-footed crow, called by many authors the corvus aquaticus, or water raven. It is about the ſize of the common raven; its beak bent like a bow, and of a blue colour; its head is ſmall; it is of a mixed brown, and red colour on the breaſt and belly, and of a finely variegated hue on the back, made up of a ſhining purple, black and green; its wings are of a fine green, which looks very bright and gloſſy in the ſun. Many authors call it the pelicanus-carbo, or corvorant. See Syſtem of Ornithology.

ACACIA, or binding bean, of the ſpecies of mimoſa, in the Linnæan ſyſtem. There are ſeveral ſpecies of this genus, but the ſort beſt known by the name of the Egyptian thorn is very common in England, and becomes in time a tree of a tolerable ſize. The flowers which grow in bunches, conſiſt each of one leaf, ſlightly divided at the extremity into five parts; the filaments are hairy and longer than the ſtyle; the flower is ſucceeded by a pod, containing ſeveral oblong ſeeds. The branches of moſt of the ſpecies of acacia are armed with ſtrong ſharp thorns. This is the plant which produces the gum-arabic.

Of the flowers of this ſpecies the Chineſe make the curious faſt yellow, which ſtains ſilk or paper, and produces an elegant and pleaſing effect, as it gives a true colour of the higheſt finiſhed ſhade of that dye.

To mention the mode of the Chineſe preparation of this dye ſtuff would amount to no more than the loſs of time in the reading, notwithſtanding the ſeveral Dictionaries lately publiſhed have dwelt upon this unintereſting proceſs.

Mr. Geoffroy attributes the origin of bezoar to the ſeeds of this plant; which, being brouſed by certain animals, and vellicating the ſtomach by their great ſourneſs and aſtringency cauſe a condenſation of the juices, till at length they become coated over with a ſtony matter, which we call *bezoar*.

There are a great many varieties of acacia, all of which may be propagated in hot beds.

Acacia *Germanica*, an inſpiſſated juice made of wild ſloes, hardly ripe. The true acacia is ſaid to be very ſcarce in the ſhops, where the German acacia is uſed in its ſtead, both being powerful aſtringents, and conſequently good in hæmorrhages and all kinds of fluxes.

Acacia, in the materia medica of the ancients, a gum made from the Egyptian acacia tree, and thought to be the ſame with our gum arabic.

The name acacia, or *ακακια*, in antiquity, implies a roll, or bag, repreſented on the medals of the Greek and Roman Emperors; ſome think it is only a handkerchief which they uſed as a ſignal; others take it for a volume, or roll of memorandums, or petitions; and finally, others will have it to be a purple bag filled with earth to remind the prince of his mortality.

Acacia *Zeylancia* ſignifies logwood.

Acacia *Indiana* ſignifies tamarind.

Acacia *Baſtard*, or *Robinia*, in botany, a genus of the diadelphia decandria claſs: for its characters. See Syſtem of Botany.

Acacia, in medicine, an inſpiſſated juice of a ſhrub of the thorn kind, uſed as an aſtringent: it is prepared by inſpiſſating to a due conſiſtence the juice diſcharged from the unripe pods of a large prickly tree of this name. It is an ingredient in the theriaca andromachi.

ACACIANS, a religious ſect; or, as ſome authors aſſert, ſeveral ſects of heretics, who maintained that the ſon was only ſimilar, and not of the ſame ſubſtance with the father: or, that he was not only a diſtinct, but a diſſimilar ſubſtance. Some of theſe ſects had their denomination from Acacias, biſhop of Cæſarea, who lived in the 4th century.

Some writers ſay, that the principal leader of theſe heretics was one Acacias, patriarch of Conſtantinople, in the 5th century.

ACADEMICIAN, or Academist, a member of an academy.

ACADEMICS, or Academists, a denomination given to the cultivators of a ſpecies of philoſophy originally derived from Socrates, and afterwards illuſtrated and enforced by Plato, who taught in a grove near Athens, conſecrated to the memory of Academus, an Athenian hero; from which circumſtance this philoſophy received the name of *academical*. Before the days of Plato philoſophy had, in a great meaſure, fallen into contempt. The contradictory ſyſtems and hypotheſes which had ſucceſſively been introduced into the world were become ſo numerous, that, from a view of this inconſiſtency and uncertainty of human opinions, many were led to conclude, that truth lay beyond the reach of our comprehenſion. Abſolute and univerſal ſcepticiſm were the natural conſequences of this concluſion. In order to remedy this abuſe of philoſophy and of the human faculties, Plato made uſe of the principles of the academical philoſophy; and, in his Phædo, reaſons in the following manner: "If we are unable to diſcover truth, ſays he, it muſt be owing to two circumſtances: either there is no truth in the nature of things, or the mind, from a defect in its powers, is not able to comprehend it. Upon the latter ſuppoſition, all the uncertainty and fluctuation in the opinions and judgments of mankind admit of an eaſy ſolution: let us therefore be modeſt, and aſcribe our errors to the real weakneſs of our own minds, and not to the nature of things themſelves. Truth is often difficult of acceſs: in order to come at it we muſt proceed with caution and diffidence, carefully examining every ſtep; and, after all our labour, we ſhall frequently find our greateſt efforts diſappointed, and be obliged to confeſs our ignorance and weakneſs."

Several of our modern philoſophers have plunged themſelves into an abſurd and ridiculous kind of ſcepticiſm. They pretend to diſcredit ſubjects that are plain, ſimple, and eaſily comprehended; but give peremptory and deciſive judgments upon things that evidently exceed the limits of our capacity. Of theſe, Berkley and Hume are the moſt conſiderable. Berkley denied the exiſtence of every thing, excepting his own ideas. Mr. Hume has gone a ſtep further, and queſtioned even the exiſtence of ideas; but at the ſame time has not heſitated to give determined opinions with regard to eternity, providence, and a future ſtate, miraculous interpoſitions of the Deity, &c. ſubjects far above the reach of our faculties. In his Eſſay on the academical or ſceptical philoſophy he has confounded two very oppoſite ſpecies of philoſophy. After the days of Plato, indeed, the principles of the firſt academy were groſsly corrupted by Arceſilas, Carneades, &c. This might lead Mr. Hume into the notion that the *academical* and *ſceptical* philoſophy were ſynonimous terms. But no principles can be of a more oppoſite nature than thoſe which are inculcated by the old academy of Socrates and Plato, and the ſceptical notions which were propagated by Arceſilas, Carneades, and the other diſciples of the ſucceeding academies.

ACADEMY, in antiquity, a garden, villa, or grove, ſituated within a mile of Athens, where Plato and his followers held their philoſophical conferences. It took its name from one Academus, or Ecademus, who was the original owner of it, and made it a kind of gymnaſium: he lived in the time of Theſeus; and, after his death, it retained his name, and was conſecrated to his memory. Cimon embelliſhed it with fountains, trees, and walks; but Sylla, during the ſiege of Athens, employed theſe very trees in making battering engines againſt the city. Cicero too had his villa, or place of retirement, near Puzzuoli, which he alſo named an *academy*, where he compoſed his *academical queſtions*, and his book *De natura Deorum*.

Academy, among the moderns, is moſt commonly uſed to ſignify a ſociety of learned men, eſtabliſhed for the improvement of any art or ſcience, and generally under the protection of a prince.

The firſt academy we read of was eſtabliſhed by Charlemagne, at the inſtigation of Alcuin. It was compoſed of the chief wits of the court, the emperor himſelf being a member. In their academical conferences, every perſon was to give an account of what ancient authors he had read; and each even aſſumed the name of ſome ancient author who pleaſed him moſt, or ſome celebrated perſon of antiquity. Alcuin, from whoſe letters we learn theſe particulars, took that of Flaccus, the ſurname of Horace: a young lord, named Augilbert, took that of Homer: Adelard, biſhop of Corbie, was called Auguſtin: Riculſe, biſhop of Mentz, was Dametas; and the king himſelf, David. This ſhews the miſtake of ſome modern writers, who relate, that it was in conformity with the genius of the learned men of thoſe times, who were great admirers of Roman names, that Alcuin took the name of Flaccus Albinus. In giving an account of the principal academies in Europe, we ſhall arrange them in order:

I. *Medical* Academies, as that of the Naturæ Curioſi in Germany; that founded at Palermo in 1645; another at Venice in 1701; another at Geneva in 1715, in the houſe of M. Le Clerc. The college of phyſicians at London and Edinburgh are alſo, by ſome, ranked in the number of *Academies*.

The academy of Naturæ Curioſi, called alſo the Leopoldine Academy, was founded in 1652 by Jo. Laur. Bauſchius, a phyſician; who, in imitation of the Engliſh, publiſhed an invitation to all phyſicians to communicate their extraordinary caſes; and, meeting with ſucceſs, was elected preſident. Their works were at firſt publiſhed ſeparately; but in 1670 a new ſcheme was laid for publiſhing a volume of obſervations every year. The firſt volume appeared in 1684, under the title of Ephemerides, and the work has been continued with ſome interruptions and variations of the title, &c. In 1687, the Emperor Leopold took the ſociety under his protection, granting the members ſeveral privileges, particularly that their preſidents ſhould be counts palatine of the holy Roman empire.

II. *Chirurgical* Academies, inſtituted ſome years ago, by public authority, at Paris: the members of which were not only to publiſh their own and correſpondents obſervations and improvements, but to give an account of all that was publiſhed on ſurgery, and to compoſe a complete hiſtory of the art, by their extracts from all the authors ancient and modern who had written on it. A queſtion in ſurgery is annually propoſed by the academy, and a gold medal of 200 livres value given to him who furniſhes the moſt ſatisfactory anſwer.

Academy *of Surgery at Vienna*, was inſtituted ſome years ago by the preſent emperor, under the direction of the celebrated Brambilla. The emperor, with his uſual liberality, has provided a large and ſplendid edifice in Vienna, which affords habitation both for the teachers, the ſtudents, pregnant women, patients for clinical lectures, and ſervants. He has alſo purchaſed for the uſe of this academy a medical library; ſets of chirurgical inſtruments; an apparatus for experiments in natural philoſophy; a collection of natural hiſtory; a number of anatomical and pathological preparations.

Among other parts of this inſtitution three prize-medals, each of the value of 40 florins, are annually beſtowed on thoſe ſtudents who return the beſt anſwer to queſtions propoſed the year before. Theſe prizes are not entirely founded by the emperor, but are in part owing to the liberality of Brendellius the protochriurgus at Vienna.

III. *Eccleſiaſtical* Academies; as that at Bologna in Italy, inſtituted in 1687, employed in the examination of the doctrine, diſcipline, and hiſtory, of each age of the church.

IV. *Coſmographical* Academy, at Venice, called the Argonauts. This was inſtituted at the ſolicitation of F. Coronelli, for the improvement of geographical knowledge. Its deſign was to publiſh exact maps, both celeſtial and terreſtrial, as well particular as general, together with geographical, hiſtorical, and aſtronomical deſcriptions. Each member, in order to defray the expence of ſuch a publication, was to ſubſcribe a proportional ſum, for which they were to receive copies of each each piece publiſhed.

V. Academies *of Sciences*. Theſe comprehend ſuch as are erected for improving natural and mathematical knowledge. They are otherwiſe called philoſophical and phyſical academies. The firſt of theſe was inſtituted at Naples, about the year 1560, in the houſe of Baptiſta Porta. It was called the Academy *Secretorum Naturæ*.

The Academy of Roſſano, in the kingdom of Naples, was originally an academy of Belles Letters, founded in 1540, and transformed into an academy of ſciences in 1695, at the ſolicitation of the learned abbot Don Giacinto Gimma; who being made preſident, under the title of promoter general, gave them a new ſet of regulations. He divided the academiſts into the following claſſes: grammarians, rhetoricians, poets, hiſtorians, philoſophers, phyſicians, mathematicians, lawyers, and divines, with a claſs apart for cardinals and perſons of quality. To be admitted a member, a man muſt have ſome degrees in the faculty. The member are not allowed to take the title of academiſts in the beginning of their books, without a written permiſſion from their preſident, which is not granted till the work has been examined by the cenſors of the academy; and the permiſſion is the greateſt honour the academy can confer, as they adopt the work, and are anſwerable for it againſt all criticiſms that may be made upon it. To this law the preſident or promoter himſelf is ſubject; and no academiſt is allowed to publiſh any thing againſt the writings of another without leave from the ſociety.

F. Merſenne is ſaid to have given the firſt idea of a philoſophical academy in France, towards the beginning of the 17th century, by the conferences of naturaliſts and mathematicians occaſionally held at his lodgings. F. Merſenne propoſed certain problems to examine, or experiments to be made. Theſe private aſſemblies were ſucceeded by more public ones. The French example animated ſeveral Engliſh men of diſtinction and learning to erect a kind of philoſophical academy at Oxford, towards the cloſe of Oliver Cromwell's adminiſtration; which, after the reſtoration, was erected into a royal ſociety.

Lewis XIV. in 1666, aſſiſted by the counſels of M. Colbert, founded an academy of ſciences at Paris, with a ſufficient revenue to defray the charge of experiments, and ſalaries to the members.

Royal Academy *of Sciences.* After the peace of the Pyrenees, Lewis XIV. being deſirous of eſtabliſhing the arts, ſciences, and literature, upon a ſolid foundation, directed M. Colbert to form a ſociety of men of known abilities and experience in the different branches, who ſhould meet together under the king's protection, and communicate their reſpective diſcoveries.

In a ſhort time, the claſſes of hiſtory, Belles Lettres, &c. were united to the French academy, which was originally inſtituted for the improvement and refining the French language; ſo that the royal academy containined only two claſſes, viz. that of natural philoſophy and mathematics.

In 1696 the king, by a proclamation, gave this academy a new form, and put it upon a more reſpectable footing. It was to conſiſt of four kinds of members viz. *honorary*, *penſionary*, *aſſociates*, and *elves*.

Notwithſtanding the advantages which the members of this academy enjoy over others, in having their expences defrayed, and even being paid for their time and attendance, they have fallen under ſome imputations, particularly that of plagiariſm, or borrowing their neighbours inventions; but with what juſtice we do not ſay.

The French have alſo conſiderable academies in moſt of their great cities: as, at Montpelier, a royal academy of ſciences on the ſame plan as that at Paris; at Thoulouſe is an academy under the denomination of Lanterniſts; others at Niſmes, Arles, Lyons, Dijon, Bourdeaux, &c.

The Royal Academy of Sciences at Berlin was founded in 1700 by Frederic II. king of Pruſſia, on the model of that of England; beſides natural knowledge, it likewiſe comprehends the Belles Lettres. In 1710 it was ordained that the preſident ſhould be one of the counſellors of ſtate, and nominated by the king. The members were divided into four claſſes; the firſt for proſecuting phyſics, medicine, and chemiſtry; the ſecond for mathematics, aſtronomy, and mechanics; the third for the German language and the hiſtory of the country; and the fourth for oriental learning.

Frederic III. the late king of Pruſſia, gave new vigour to this academy, by inviting to Berlin ſuch foreigners as were moſt diſtinguiſhed for their merit in literature, and encouraged his ſubjects to proſecute the ſtudy and cultivation of the ſciences by giving ample reward; he gave a new regulation to the academy, and took upon himſelf the title of its protector.

The academiſts hold two public aſſemblies annually; one in January, on the late king's birth-day; and the other in May, on the day of his acceſſion to the throne. At the latter of theſe is given, as a prize, a gold medal of 50 ducats value: the ſubject for this prize is ſucceſſively, natural philoſophy, mathematics, metaphyſics, and erudition.

The Imperial Academy of Sciences at Peterſburgh was projected by Peter the Great. That great monarch having, during his travels, obſerved the advantage of public ſocieties for the encouragement and promotion of literature, formed the deſign of founding an academy of ſciences at Peterſburgh. By the advice of Wolf and Leibnitz, whom he conſulted on this occaſion, the ſociety was regulated, and ſeveral learned foreigners were invited to become members. Peter himſelf drew the plan, February 1724.

The preſent empreſs Catharine III. with her uſual zeal for promoting the diffuſion of knowledge, has taken this uſeful ſociety under her more immediate protection. She has altered the court of directors greatly to the advantage of the whole body; has corrected many abuſes, and infuſed a new ſpirit into their reſearches. By her majeſty's particular recommendation, the moſt ingenious profeſſors have viſited the various provinces of her vaſt dominions; and as the fund of the academy was not ſufficient to ſupply the whole expence of theſe ſeveral expeditions, the empreſs beſtowed the ſum of 2000l. which ſhe has renewed as occaſion required.

The purpoſe and intent of theſe travels will appear from the inſtructions given by the academy to the ſeveral perſons who were engaged in them. They were ordered to purſue their inquiries upon the different ſorts of earths and waters; upon the beſt methods of cultivating the barren and deſert ſpots; upon the local diſorders incident to men and animals, and the moſt efficacious means of relieving them; upon the breeding of cattle, and particularly of ſheep; on the rearing of bees and ſilk-worms; on the different places and objects for fiſhing and hunting; on minerals; on the arts and trades; and on forming a Flora Ruſſica, or collection of indigenous plants: they were particularly inſtructed to rectify the longitude and latitude of the principal towns; to make aſtronomical, geographical, and meteorological obſervations; to trace the courſe of the rivers; to take the moſt exact charts; and to be very diſtinct and accurate in remarking and deſcribing the manners and cuſtoms of the different people, their dreſſes, languages, antiquities, traditions, hiſtory, religion; and, in a word, to gain every information which might tend to illuſtrate the real ſtate of the whole Ruſſian empire.

In conſequence of theſe expeditions, perhaps no country can boaſt, within the ſpace of ſo few years, ſuch a number of excellent publications on its internal ſtate, on its natural productions, on its topography, geography, and hiſtory; on the manners, cuſtoms, and languages of the different people, as have iſſued from the preſs of this academy.

Their works abound with ingenious and elaborate diſquiſitions upon various parts of ſcience and natural hiſtory, and which reflect the greateſt honour upon their authors; and it may not be an exaggeration to aſſert, that no ſociety in Europe has more diſtinguiſhed itſelf for the excellence of its publications, and particularly in more abſtruſe parts of the pure and mixed mathematics.

They have an extenſive library conſiſting of 36000 curious books and manuſcripts, and a muſeum, in which the various branches of natural hiſtory, &c. are diſtributed in different apartments: it is extremely rich in native productions, having been conſiderably augmented with a variety of ſpecimens collected by Pallas, Gmelin, Guldenſtaedt, and other learned profeſſors, during their late expeditions through the Ruſſian empire. The ſtuffed animals and birds occupy one apartment. The chamber of rarities, the cabinet of coins, &c. contain innumerable articles of the higheſt curioſity and value. The ſociety has this modeſt motto, *Paulatim*.

The Academy of Sciences at Bologna, called the Inſtitute of Bologna, was founded by count Marſigli in 1712, for the cultivation of phyſics, mathematics, medicine, chemiſtry, and natural hiſtory.

The Academy of Sciences at Stockholm, or Royal Swediſh Academy, owes its inſtitution to ſix perſons of diſtinguiſhed learning, amongſt whom was the celebrated Linnæus: they originally met on the 2d of June 1739, formed a private ſociety, in which ſome diſſertations were read; and in the latter end of the ſame year their firſt publication made its appearance. As the meetings continued and the members increaſed, the ſociety attracted the notice of the king, and was, on the 31ſt of March 1741, incorporated under the name of the Royal Swediſh Academy.

The king is ſometimes preſent at the ordinary meetings, and particularly at the annual aſſembly in April for the election of members. Any perſon who ſends a treatiſe which is thought worthy of being printed, receives the tranſactions for that quarter gratis, and a ſilver medal, which is not eſteemed for its value, being worth only three ſhillings, but for its rarity and the honour conveyed by it. All the papers relating to agriculture are put forth ſeparately under the title of *Oeconomica acta*. Annual premiums, in money and gold medals, principally for the encouragement of agriculture and inland trade, are alſo diſtributed by the academy. The fund for theſe prizes is ſupplied from private donations.

The Royal Academy of Sciences of Copenhagen owes its inſtitution to the zeal of ſix literati, whom Chriſtian VI. in 1742, ordered to arrange his cabinet of medals. Theſe perſons occaſionally meeting for that purpoſe, extended their deſigns; aſſociated with them others who were eminent in ſeveral branches of ſcience; and forming a kind of literary ſociety, employed themſelves in ſearching into, and explaining, the hiſtory and antiquities of their country.

In 1743 his Daniſh majeſty took it under his protection, called it the Royal Academy of Sciences, endowed it with a fund, and ordered the members to join to their former purſuits natural hiſtory, phyſics, and mathematics.

The American Academy of Sciences was eſtabliſhed in 1780 by the council and houſe of repreſentatives in the province of Maſſachuſet's Bay, for promoting the knowledge of the antiquities of America, and of the natural hiſtory of the country; for determining the uſes to which its various natural productions might be applied; for encouraging medicinal diſcoveries, mathematical diſquiſitions, philoſophical inquiries and experiments, aſtronomical, meteorological, and geographical obſervations, and improvements in agriculture, manufactures, and commerce,; and, in ſhort, for cultivating every art and ſcience which may tend to advance the intereſt, honour, dignity, and happineſs, of a free and independent people. The members of this academy are never to be more than 200, nor leſs than 40.

The Royal Academy of Arts in London was inſtituted for the encouragement of deſigning, painting, ſculpture, &c. &c. in the year 1768. This academy is under the immediate patronage of the king, and under the direction of 40 artiſts of the firſt rank in their ſeveral profeſſions. It furniſhes, in winter, living models of different characters to draw after; and, in ſummer, models of the ſame kind to paint after. Nine of the beſt academicians are annually elected out of the 40, whoſe buſineſs is to attend by rotation, to ſet figures, to examine the performance of the ſtudents, and to give them neceſſary inſtructions. There are likewiſe four profeſſors, namely, of painting; architecture; anatomy; and perſpective; who annually read public lectures on the ſubjects of their ſeveral departments; beſide a preſident, a council, and other officers. The admiſſion to this academy is free to all ſtudents properly qualified to reap advantage from the ſtudies cultivated in it; and there is an annual exhibition of paintings, ſculptures, and deſigns, open to all artiſts of diſtinguiſhed merit.

The Academy of Painting and Sculpture at Paris took its riſe from the diſputes that happened between the painters and ſculptors in that capital. The academy conſiſts of a protector; a vice-protector; a director; a chancellor; four rectors; adjuncts to the rectors; a treaſurer; four profeſſors, one of which is profeſſor of anatomy, and another of geometry; ſeveral adjuncts and counſellors, an hiſtoriographer, a ſecretary, and two uſhers.

The Academy of Painting holds a public aſſembly every day for two hours in the afternoon, to which the painters reſort either to deſign or to paint, and where the ſculptors model after a naked perſon. There are 12 profeſſors, each of whom keeps the ſchool for a month; and there are 12 adjuncts to ſupply them in caſe of need. The profeſſor upon duty places the naked man as he thinks proper, and ſets him in two different attitudes every week. This is what they call ſetting the model. In one week of the month he ſets two models together, which is called ſetting the group. The paintings and models made after this model, are called Academics, or Academy-figures. They have likewiſe a woman who ſtands for a model in the public ſchool. Every three months, three prizes for deſign are diſtributed among the elves or diſciples; two others for painting, and two for ſculpture, every year.

There is alſo an Academy of Painting, Sculpture, &c. at Rome, eſtabliſhed by Lewis XIV. wherein thoſe who have gained the annual prize at Paris are intitled to be three years entertained at the king's expence, for their further improvement.

The Academy of Architecture, eſtabliſhed by M. Colbert in 1671, conſiſting of a company of ſkilful architects, under the direction of the ſuperintendant of the buildings.

The Academy of Dancing, erected by Lewis XIV. with privileges above all the reſt.

VI. Academies of Law; as that famous one at Beryta, and that of the Sitientes at Bologna.

VII. Academies of Hiſtory; as the Royal Academy of Portugueſe Hiſtory at Liſbon. This academy was inſtituted by king John V. in 1720. It conſiſts of a director, four cenſors, a ſecretary, and 50 members; to each of whom is aſſigned ſome part of the eccleſiaſtical or civil hiſtory of the nation, which he is to treat either in Latin or Portugueſe. The civil hiſtory compriſes the tranſactions of the kingdom from the government of the Romans down to the preſent time.

VIII. Academies of Antiquities; as that at Cortona in Italy, and at Upſal in Sweden. The firſt is deſigned for the ſtudy of Hetrurian antiquities; the other for illuſtrating the Northern languages, and the antiquities of Sweden. One of their laws is to give audience to poets only one day in the year; another is to fix their ſeſſions, and impoſe a tax of a diſſertation on each member in his turn.

The Academy of Medals and Inſcriptions at Paris was formed by M. Colbert, under the patronage of Lewis XIV. in 1663, for the ſtudy and explanation of ancient monuments, and perpetuating great and memorable events, eſpecially thoſe of the French monarchy, by coins, relievos, inſcriptions, &c.

One of the firſt undertakings of this academy was to compoſe, by means of medals, a connected hiſtory of the principal events of Lewis XIV's reign: but in this deſign they met with great difficulties, and of conſequence it was interrupted for many years; but at length it was completed down to the advancement of the duke of Anjou to the crown of Spain.

IX. **Academies** *of Belles Lettres* are thoſe wherein eloquence and poetry are chiefly cultivated. Theſe are very numerous in Italy, and not uncommon in France.

The Academy of Umidi at Florence has contributed greatly to the progreſs of the ſciences by the excellent Italian tranſlations given, by ſome of its members, of the ancient Greek and Latin hiſtorians. Their chief attention is to the Italian poetry, at the ſame time that they have applied themſelves to the poliſhing of their language, which produced the Academy la Cruſca.

In 1690 the Academy of Arcadi was eſtabliſhed at Rome, for reviving the ſtudy of Poetry and of the Belles Lettres. Beſides moſt of the politer wits of both ſexes in Italy, this academy comprehends many princes, cardinals, and other eccleſiaſtics; and, to avoid diſputes about pre-eminence, all appear maſked after the manner of the Arcadian ſhepherds. Within ten years from its firſt eſtabliſhment, the number of academiſts amounted to ſix hundred. They hold aſſemblies ſeven times a year in a mead or grove, or in the gardens of ſome nobleman of diſtinction. Six of theſe meetings are employed in the recitation of poems and verſes of the Arcadi reſiding at Rome; who read their own compoſitions; except ladies and cardinals, who are allowed to employ others. All the members of this body, at their admiſſion, aſſume new paſtoral names, in imitation of the ſhepherds of Arcadia. The academy has ſeveral colonies of Arcadi in different cities of Italy, who are all regulated after the ſame manner.

X. Academies of Languages; called by ſome, grammatical academies: as,

The Academy della Cruſca at Florence, famous for its vocabulary of the Italian tongue, was formed in 1582, but ſcarce heard of before the year 1584, when it became noted for a diſpute between Taſſo and ſeveral of its members. Many authors confound this with the Florentine academy.

The French Academy, which had its riſe from a meeting of men of letters in the houſe of M. Conrart, in 1629. In 1635 it was erected into an academy, by Cardinal Richlieu, for refining and aſcertaining the French language. Noblemen or perſons of diſtinction are not admitted on any other introduction than as men of letters. They have been ſeverely ſatyrized, and their ſtyle has been ridiculed as enervating inſtead of refining the French language. They are alſo charged with having ſurfeited the world by flattery, and having exhauſted all the topics of panegyric in praiſe of their founder; it being a duty incumbent on every member, at his admiſſion, to make a ſpeech in praiſe of the king.

The Royal Spaniſh Academy at Madrid held its firſt meeting in July 1713, in the palace of its founder, the duke d'Eſcalona. It conſiſted at firſt of eight academiſts, including the duke; to which number 14 others were afterwards added, the founder being choſen preſident or director. Their object, as marked out by the royal declaration, was to cultivate and improve the national language: they were to begin with chooſing carefully ſuch words and phraſes as have been uſed by the beſt Spaniſh writers, and to compoſe a Dictionary of their language.

XI. Academies of Politics; as that at Paris, conſiſting of ſix perſons, who met at the Louvre, in the chamber where the papers relating to foreign affairs were lodged. But this academy proved of little ſervice, as the kings of France were unwilling to truſt any but their miniſters with the inſpection of foreign affairs.

Academy is alſo a term for ſchools and other ſeminaries of learning among the Jews, where their rabbins and doctors inſtructed their youth in the Hebrew language.

The Romans had a kind of military academies, eſtabliſhed in all the cities of Italy, under the name of Campi Martis. The youth were admitted to be trained for war at the public expence. The Greeks, beſide academies of this kind, had military profeſſors called Tactici, who taught all the higher offices of war, &c. &c.

Academy is often uſed with us to denote a kind of collegiate ſeminary, where youth are inſtructed in arts and ſciences. There is one at Portſmouth for teaching navigation, drawing, &c. another at Woolwich, for fortification, gunnery, &c. Beſides theſe, there are numerous academies, eſpecially in London, for teaching mathematics, languages, writing, accounts, drawing, and other branches of learning.

The non-conformiſt miniſters, &c. are bred up in private academies; as not approving the common univerſity education. The principal of their academies are thoſe in London, Daventry, and Warrington.

Academy *Figure*, a drawing of a naked man or woman, taken from the life; which is uſually done on paper with red or black chalk, and ſometimes with pencils or crayons.

ACÆNA, *αχαινα*, in antiquity, a Grecian meaſure of length, equal to 10 feet Britiſh.

Acæna, in botany, a genus of the monogynia order, belonging to the tetrandria claſs of plants; the characters of which are theſe: the calyx is a perianthium, conſiſting of four leaves, which are ovate, concave, equal, and perſiſtent; there is no corolla: the ſtamina conſiſts of four equal middle ſized filaments oppoſite to the calyx; the antheræ are quadrangular, twin erect: the piſtillum has an inverſely-ovate hiſped germ: the ſtylus is ſmall, and inflected on one ſide; and the ſtigma is a ſmall thickiſh coloured membrane, divided into many ſegments: the pericarpium is an inverſely ovated dry one celled berry, covered with prickles, bent backwards: the ſeed is ſingle. There is but one ſpecies, a native of Mexico.

ACAIBA, in botany, the ſame as,

ACAJOU, the name of a genus of plants, called by botaniſts, anacardium, or Weſt Indian caſhew-nut trees, the characters of which are; the empalement is of one leaf, erect and cut into five ſegments: the flower is alſo of one leaf, having a ſhort tube, and cut into five parts at the top; the ten ſtamina are as long as the petals, and crowned with ſmall ſummits: in the center is a round germen, ſupporting an awl, ſhaped ſtyle, crowned with an acute ſtigma; the germen becomes a large oval fleſhy fruit, having a large kidney ſhaped nut growing to its apex. See Acardium. Lin. Gen. Plant. 467.

The juice of this fruit, when duly fermented, intoxicates like wine. It is ſaid to ſtop a diarrhœa, and cure a diabetes. Authors aſſert, that the Indians uſe it as a provocative to venery: they are ſaid to extract oil from the ſhells, which is uſed by painters, to give their colour a laſting black, and alſo to keep wood from decay.

ACALEPHE, a nettle, whoſe ſummit grows red and ſeedy.

Acalephe, a fiſh whoſe fleſh is remarkably tender. Gellius.

Acalephe, a ſea-fowl, ſomewhat like a mallard. Nicander.

ACALEPTIC, in ancient proſody, a complete verſe.

ACALYPHA, in botany, a genus of plants of the monœcia adelphia claſs, and are of four ſpecies. Lin. Syſ.

As the acalypha, or three-ſeeded mercury, is ſeldom preſerved, even in botanic gardens, having neither uſe or beauty to form any part of its characteriſtic, we omit its deſcriptive characters.

ACALCUM, tin.

ACAMATOS, among practitioners in phyſic, implies that diſpoſition of a limb which is equally diſtant from flexion and extenſion.

ACANACEOUS *Plants*, the ſame as acanthaceous, i. e. ſuch as are armed with thorns or prickles.

ACANAPHORA, the ſame as centuary.

ACANGIS, *Adventurers*, the Turkiſh huſſars, or light troops, who are employed as ſcouts on the frontiers of an enemy's country.

ACANOR, a chemical furnace of a particular conſtruction.

ACANTHA, a technical term amongſt botaniſts, to ſignify the thorns of plants: formed of the Greek words, ακη, point, and ανθος, flower. The term is alſo applied to the prickles, or thorns of fiſh.

Acantha, in anatomy, is applied to the poſterior protuberances of the vertebræ of the back, forming what we call the ſpina dorſi, or back bone.

ACANTHABOLUS, in ſurgery, an inſtrument for pulling thorns, or the like, out of the ſkin.

A tweezer is ſometimes called an acanthabolus. The word is compounded of ακανθα, a thorn, and βαλλω, to caſt away. Sometimes it is called velſella, for its figure, &c. See Instruments in Surgery, in the plate under that name; agreeably to the Modern Syſtem of Surgery.

ACANTHALZUCA, the ſame as echinopus, or globe thiſtle.

ACANTHE, the ſame as artichoke.

Acanthe *Arabica*, an oriental plant, uſed in medicine, ſeldom enumerated in botany.

ACANTHIAS, in ichthyology, a name given by ſome authors to the fiſh, whoſe ſkin is uſed by caſe-makers; under the general, but ſimple, denomination of *fiſh-ſkin*. It is claſſed as the galens.

ACANTHICE, maſtich, among ancient naturaliſts, a kind of gum, producing from the herb helxine.

ACANTHINE, Acanthinus, denotes a thing, relating to, or reſembling the herb acanthus: as, acanthina veſtimenta, acanthine garments, of which we have two different explications.

Embroidery, is ſaid to be invented to imitate the Egyptian acanthus; ſilken ſtuffs alſo go by this name.

Plin. Hiſt. Nat. lib. 14. *c.* 12 *Hard. Not.*

ACANTHINAM *Lignum*, brazil wood.

ACANTHION, a plant of the thiſtle kind, whoſe down makes a ſort of ſtuff not unlike ſilk.

ACANTHIS, in ornithology, a ſpecies of the goldfinch.

ACANTHOPTERYGII, in ichthyology, one of the claſſes, containing 17 genera of fiſhes, whoſe fins are bony and prickly at the extremities. The name is derived from the Greek words, ακανθα, a thorn, and πτερυγιον, a fin. See Syſtem of Ichthyology.

ACANTHUS, in botany, the branca urſini, bear's-foot, brank urſine, or bear's-breech; a genus of the angioſpermia order, belonging to the didynamia claſs of plants; and ranked in the 40th natural order perſonatæ. See Syſtem of Botany.

Acanthus, in architecture, an ornament repreſenting the leaves of the acanthus, uſed in the capitals of the Corinthian and Compoſite orders. See Syſtem of Architecture.

ACANUS, a ſpecies of the carduus or thiſtle.

ACAPATLI, the botanical name of the plant, which produces the long pepper.

ACAPNON, marjoram, called by the Greeks, ἄκαπνον, or dry wood.

ACARA, a ſmall freſh water fiſh, caught in the Brazils.

ACARAAYA, a ſea fiſh, common to the Brazilians.

ACARAMUCU, a ſmall fiſh.

ACARAPEBA, a ſmall Brazilian fiſh.

ACARAPITAMA, a beautiful Brazilian fiſh, reſembling a mullet.

ACARAPUCU, a freſh water Brazilian fiſh.

ACARAUNA, a ſmall American fiſh, called by our ſailors, the Old Wife. See Syſtem of Ichthyology.

ACARI, or Acarus, the tick or mite, a genus of inſects belonging to the order of aptera, or ſuch as have no wings. The acarus has eight legs, two eyes, one on each ſide of the head; and two jointed tentacula. The female is oviparous.

The ſiro or cheeſe-mite, is a very minute ſpecie. To the naked eye theſe mites appear like moving particles of duſt; but the microſcope diſcovers them to be perfect animals, having as regular a figure, and performing all the functions of life, as perfectly as creatures that exceed them in bulk. The principal parts of them are the head, the neck, and the body. The head is ſmall in proportion to the body; and has a ſharp ſnout, and a mouth that opens and ſhuts like a mole's. They have two ſmall eyes, and are extremely quick-ſighted; and when they have been once touched with a pin you will eaſily perceive how cunningly they avoid a ſecond touch. Their legs are each furniſhed at the extremity with two little claws, with which the animal very nicely takes hold of any thing. The hinder part of the body is plump and bulky; and ends in an oval form, from which there iſſue a few exceeding long hairs. Other parts of the body are alſo covered with thin and long hairs. The males and females are eaſily diſtinguiſhed in theſe little animals. The females are oviparous, as the louſe and ſpider; and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are, however, when firſt hatched, extremely minute; and, in their growing to their full ſize, they caſt their ſkins ſeveral times. Theſe little creatures may be kept alive many months between two concave glaſſes, and applied to the microſcope at pleaſure. They are thus often ſeen in coitu, conjoined tail to tail; and this is performed by an incredibly ſwift motion. Their eggs, in warm weather, hatch in 12 or 14 days; but in winter they are much longer. Theſe eggs are ſo ſmall, that a regular computation ſhows, that 90 millions of them are not ſo large as a common pigeon's egg. They are very voracious animals, and have often been ſeen to eat one another. Their manner of eating is by thruſting alternately one jaw forward and the other backward, and in this manner grinding their food; and after they have done feeding they ſeem to chew the cud. There are ſeveral varieties of this ſpecies found in different ſubſtances beſides cheeſe; as in malt-duſt, flour, oatmeal, &c. Thoſe in malt duſt and oatmeal are much nimbler than the cheeſemites, and have longer hairs. There are alſo a ſort of wandering mites, which range wherever there is any thing they can feed on: they are often ſeen in the form of a white duſt, and are not ſuſpected to be living creatures. The mite is called by authors, ſimply, *acarus*. It is an animal very tenacious of life, and will live months without food. Mr. Lewenhoek had one lived 11 weeks in a ſituation he had fixed it for examining by his microſcope.

Linnæus enumerates 35 ſpecies, of which ſome are inhabitants of the earth, ſome of waters; ſome live on trees, others among ſtones, and others on the bodies of different animals, and even under their ſkin.

ACARNA, in botany, the name of the artichoak.

ACARNAN, in ichthyology, a ſmall ſea fiſh, common in the Mediterranean, ſuppoſed to be of the ſame ſpecies with the rubellio, or erythrinus.

ACARON, the wild myrtle.

ACARTUM, red lead.

ACARUS, the ſame as acari.

ACATALECTIC, a term in ancient poetry for ſuch verſes as have all their feet or ſyllables.

ACATALEPSY, in philoſophy, ſignifies the impoſſibility of comprehending ſomething. The diſtinguiſhing tenet of the pyrrhoniſts was their aſſerting an abſolute acatalepſy in regard to every thing.

ACATALUS, a juniper berry.

ACATASTATOS, inconſiſtent, a term in medicine applied to irregular fevers, whoſe paroxiſms are uncertain, and which are indicated by frequent changes in the urine. It is likewiſe applied to thoſe ſhivering fits in fevers, which have no conſtant return, and to turbid urine that depoſits no regular ſediment.

ACATERY, anciently an officer in the king's houſhold, deſigned as a check between the clerks of the kitchen and the clerks of the houſhold or purveyors.

ACATHARSIA, in medicine, an impurity of the blood or humours.

ACATHISTUS, in divinity, the name of a ſolemn hymn, anciently ſung in the Greek church, on Saturday, of the 5th week of Lent, in honor of the Virgin Mary, for having thrice delivered Conſtantinople from the hands of barbarous nations.

ACATIUM, in the ancient navigation, a kind of boat or pinnace uſed for military purpoſes. The acatium was a ſpecies of thoſe veſſels called naves actuariæ, i. e. ſuch as were wrought with oars. It was ſometimes made uſe of in battle. Strabo deſcribes it as a privateer or pirate ſloop.

ACAULIS, in botany, a term applied to ſuch flowers as have no viſible ſtalk, but appear to reſt upon the ground.

ACAULOSE, in botany, implies ſuch plants as have no caulis or ſtem; ſuch as the carline-thiſtle, &c.

ACBAB, in ornithology, a bird found in the Philippine iſlands, which deſtroys the early ſprout of the rice, ſo that the inhabitants are continually guarding againſt ſo injurious an enemy of this autumnal increaſe.

ACBAR, an ancient Arabian idol, deſtroyed at the time of Mahomet's propagation of his religion in Arabia.

ACCADEMIA, in muſic, implies a concert.

ACCALIA, in Roman antiquity, ſolemn feaſts held in honor of Acca Laurentia, Romulus's nurſe; they were otherwiſe called, Laurentalia.

ACCAPITARE, in ancient law, the act of becoming the vaſſal of a lord.

ACCAPITUM ſignifies a ſum paid as a fine by the tenant on his homage as a copyholder.

ACCAZDIR, tin.

ACCEDAS *ad curiam*, in law, a writ which lies for him who fears falſe impriſonment, or falſe judgment, in an inferior court.

Accedas *ad vicecomitem*, a writ directed to the coroner commanding him to deliver a writ to the ſheriff, who hath ſuppreſſed a pone delivered to him.

ACCELERATED, in a general ſenſe, ſignifies a thing continually increaſing, or growing longer in ſubſtance.

ACCELERATION, in mechanics, the increaſe of velocity in a moving body. Accelerated motion is that which continually receives freſh acceſſions of velocity. Acceleration ſtands immediately oppoſed to retardation, which denotes a diminution of velocity.

Acceleration is chiefly uſed in phyſics, in reſpect of falling bodies, i. e. of heavy bodies tending towards the centre of the earth by the force of gravity.

Various were the ſyſtems and opinions which philoſophers produced to account for this acceleration. But the immediate cauſe of acceleration is now ſufficiently obvious; the principle of gravitation, which determines the body to deſcend determining it to be accelerated by a neceſſary conſequence.

Suppoſe a body let fall from on high: the primary cauſe of its beginning to deſcend is doubtleſs the power of gravity: but when once the deſcent is commenced, that ſtate becomes in ſome meaſure natural to the body; ſo that if left to itſelf, it would perſevere in it for ever, even though the firſt cauſe ſhould ceaſe: as we ſee in a ſtone caſt with the hand, which continues to move after it is left by the cauſe that gave it motion.

The motion of a body aſcending, or impelled upwards, is diminiſhed, or retarded from the ſame principle of gravity, acting in a contrary direction, in the ſame manner as a falling body is accelerated. A body thus projecting upwards riſes till it has loſt all its motion; which it does in the ſame time that a body falling would have acquired a velocity equal to that wherewith the body was thrown up. Hence the ſame body thrown up will riſe to the ſame height from which falling it would have acquired the velocity wherewith it was thrown up: and hence the heights which bodies thrown up with different velocities do aſcend to, are to one another as the ſquares of thoſe velocities.

Acceleration *of Bodies on inclined Planes*. The ſame general law obtains here as in bodies falling perpendicularly: the effect of the plane is to make the motion ſlower; but the inclination being every where equal, the retardation ariſing therefrom will proceed equally in all parts, at the beginning and the ending of the motion.

Acceleration *of the Motion of Pendulums*; the motion of pendulous bodies is celerated in their deſcent; but in a leſs ratio than that of bodies falling pependicularly. See Mechanics and Pendulum.

Acceleration *of the Motion of Projectiles*. See Projectiles.

Acceleration is alſo applied in the ancient aſtronomy, in reſpect of the fixed ſtars. This acceleration was the difference between the revolution of the *primum mobile* and the ſolar revolution; which was computed at three minutes and 56 ſeconds.

Acceleration *of the Moon*, a term uſed to expreſs the increaſe of the moon's mean motion from the ſun, compared with the diurnal motion of the earth. See Syſtem of Astronomy.

Accelerator, in anatomy, the name of two muſcles of the penis, which ſerve for ejecting the urine or ſemen. See Anatomy, *Table of the Muſcles*.

ACCENDENTES, a lower order of miniſters in the Romiſh church, whoſe office it is to light and trim the candles.

ACCENDONES, in Romiſh hiſtory, ſeconds to the Gladiators, who fought in the amphitheatres for the diverſion of the audience.

ACCENSI, in the Roman armies, ſupernumerary ſoldiers, who were held in readineſs to ſupply the places of thoſe who were ſlain in battle. Livy mentions them as undiſciplined troops. Salmaſius ſays, they were recruited, or enliſted out of the 5th claſs of the Roman citizens.

ACCENSIIS alſo imply, in the Roman law, tipſtaves, who ſummoued partiet to appear and anſwer before the judges.

ACCENSION, in philoſophy, the act of ſetting a body on fire. Thus the accenſion of gun-powder by the fire, ſtruck with the flint and ſteel of the gun lock, between the hammer and the trigger.

ACCENT, in a general ſenſe, ſignifies, a particular tone, ſtreſs, or ſtrong articulation of the voice.

Accent, in grammar, applied to ſpeaking, or reading, implies an inflection of the voice, which gives each ſyllable of a word its due pitch, whether high, low, or grave.

The word is derived from the Latin, *accentus*; and is compounded of *ad*, to, and *cano*, to ſing. *Accentus*, *quaſi adcantus*, or *juxta cantum*. In this ſenſe, *accent* is ſynonymous with the Greek, *τονος*; the Latin, *tenor*, and the Hebrew, טעם, *guſtus*, in Engliſh, *taſte*.

For the uſe of it, its marks, particulars and characters, ſee Syſtem of Grammar.

Accent, in muſic, is a certain modulation, or warbling of the ſounds, either by the voice or inſtruments, to expreſs a paſſion. Every bar, or meaſure, is divided into accented and unaccented parts; the accented are the principal, being thoſe chiefly intended to move and affect the hearer: the more full and void of diſcords the harmony is, the leſs offence to the ear will be given.

ACCENTOR denotes one of the three ſingers or players, that performs the predominant part in a trio.

ACCEPTANCE, in a general ſenſe, the act of receiving or admitting of a thing.

Acceptance, in common law, ſignifies a perſon's agreeing to offers made in bargaining, by which the bargain is concluded.

Acceptance, in civil law, implies the concurrence of the donee, which renders the act complete; it being previouſly underſtood, that the choice made by the donor is to remain irrevokeable.

Acceptance, in commerce, ſignifies the name at length, or initials of a name, ſubſcribed to a bill of exchange, by which the writer makes himſelf debtor to the drawer, payable to the indorſer or holder of the bill, for the ſum contained in the body of the writing, at a certain time therein limited. For the governing law of mercantile tranſactions relative to bills of exchange, ſee the Syſtem of Commercial Law.

ACCEPTATION, in grammar, the meaning of a word, to be underſtood, agreeably to the intention of its author.

ACCEPTER, or Acceptor, the ſubſcriber to a bill of exchange.

ACCEPTILATION, in civil law, ſignifies a diſcharge given to the debtor by the creditor, without the payment of any value.

ACCESS, in a general ſenſe, denotes the approach of one towards another.

Access, in medicine, implies the beginning of a fit of a periodical diſeaſe.

Access, in the court of the Roman Pontiff, implies the receding of the cardinal electors from their firſt ſuffrages, when the numbers are equal for the two candidates, upon an election of a Pope, ſo that they give their votes for one of the competitors, in order to augment his number and cloſe the election.

Access, in common law, a power granted to poſſeſs a benefice after the death of an incumbent; or, otherwiſe, if the party to whom the acceſs is granted ſhould be a minor, the benefice may be given to another in the interim; but when he hath attained a competent age he may enter into poſſeſſion of his benefice without any new grant or preſentation.

ACCESSIBLE, any thing that may be approached, or acceſs had to it.

ACCESSION, generally implies the joining of ſomething new to a thing exiſting previous to ſuch union.

Accession, in politics and law, ſignifies the ſucceſſion of a prince to the throne of a deceaſed monarch.

Accession, in the law of nations, implies, the ſovereign's agreeing with the political treaty of two or more potentates, or ſtates, already entered into between them.

Accession, in law, is a method of acquiring property, by which, in things that have a cloſe connection or dependence upon one another, the property of the principal thing draws after it the property of the acceſſory: thus, the owner of a cow becomes likewiſe the owner of the calf. It ſometimes likewiſe ſignifies conſent or acquieſcence.

ACCESSORY, or Accessary, ſomething that accedes, or is added to another more conſiderable thing; in which ſenſe the word ſtands oppoſed to principal.

Accessory, or Accessary, in common law, is chiefly uſed for a perſon guilty of a felonious offence, not principally, but by participation: as, by advice, command, or concealment.

There are two kinds of acceſſories: before the fact, and after it. The firſt is he who commands, or procures another to commit felony, and is not preſent himſelf; for if he be preſent, he is a principal. The ſecond is he who receives, or aſſiſts, any man that has done murder, or felony, whereof he has knowledge. A man may alſo be acceſſory to an acceſſor, by aiding, receiving, &c. an acceſſory in felony.

An acceſſory in felony ſhall have judgment of life and member, as well as the principal who did the felony; but not till the principal be firſt attainted, convicted, or outlawed thereon. Where the principal is pardoned without attainder, the acceſſory cannot be arraigned: it being a maxim in law, *Ubi non eſt principalis, non poteſt eſſe acceſſorius:* but if the principal be pardoned, or have his clergy after attainder, the acceſſory ſhall be arraigned; 4 and 5 W. et M. cap 4. And by ſtat. 1 Anne, cap. 9. it is enacted, that where the principal is convicted of felony, or ſtands mute, or challenges above 20 of the jury, it ſhall be lawful to proceed againſt the acceſſory in the ſame manner as if the principal had been attainted; and notwithſtanding ſuch principal ſhall be admitted to his clergy, pardoned, or delivered before attainder. In ſome claſſes alſo, if the principal cannot be taken, then the acceſſory may be proſecuted for a miſdemeanor, and puniſhed by fine, impriſonment, &c. In the loweſt and higheſt offences there are no acceſſories, but all are principals: as in riots, forcible entries, and other treſpaſſes, which are the loweſt offences. So alſo in the higheſt offence, which is high treaſon, there are no acceſſories.

Acceſſories, in petty treaſon, murder, and in felonies of ſeveral kinds, are not to have their clergy. There can be no acceſſory before the fact in manſlaughter; becauſe that is ſudden and unprepenſed.

ACCESSORY *Nerves*, in anatomy, nerves, which ariſing from the medulla in the vertebræ of the neck, aſcend, and enter the ſkull, and paſs out of it again with the par vagum, wrapped up in the ſame common integument, and after quitting them, are diſtributed into the muſcles of the neck and ſhoulders. See Syſtem of ANATOMY.

ACCESSORY, among painters, an epithet given to ſuch parts of an hiſtory-piece as ſerve chiefly for ornament, and might have been wholly left out: ſuch as vaſes, armour, &c.

ACCIDENCE, the firſt rudiments of the Roman language, or Latin tongue,

ACCIDENT, in a general ſenſe, denotes any ſudden misfortune.

ACCIDENT, in grammar, implies a property attached to a word, without entering into its eſſential definition; for every word, notwithſtanding its ſignification, will be either primitive, derivative, ſimple, or compound, which are the accidents of words. A word is ſaid to be primitive, when it is taken from no other word in the language in which it is uſed: thus heaven, king, good, are primitive words. It is ſaid to be derivative, when it is taken from ſome other word: thus heavenly, kingdom, goodneſs, &c. are derivatives. A ſimple word is eaſily diſtinguiſhed from a compound: thus juſt, juſtice, are ſimple words: unjuſt, injuſtice, are compound: res is a ſimple word, as well as publica; but reſpublica is a compound. Beſides theſe accidents, which are common to all ſorts of words, each particular ſpecies has its accidents: thus the accidents of the noun ſubſtantive are the gender, declenſion, and number; and the adjective has another accident, namely the compariſon. See Syſtem of GRAMMAR,

ACCIDENT, in heraldry, an additional point or mark in a coat of arms, which may be either omitted or retained without altering the eſſence of the armour; ſuch as abatement, difference, and tincture.

ACCIDENTAL, in a general ſenſe, implies all things that happen by accident.

ACCIDENTAL, in philoſophy, the effect of ſomething that flows by accident, not either guided by laws, or ſubject to the thing to which it is joined; conſequently, it is freed from return, unleſs by caſual intervening.

In this ſenſe accident is oppoſed to conſtant and principal, e. g. The ſun's place is with reſpect to the earth, the conſtant and principal cauſe of the heat in ſummer, and the cold in winter; whereas winds, ſnows, and rains, are the accidental cauſes which often alter and modify the action of the principal cauſe.

ACCIDENTAL *Point*, in perſpective, is that point in the horizontal line where the projections of two lines parallel to each other meet the reſpective plane.

ACCIDENTAL *Colours* are thoſe which depend upon the affections of the eye, in contradiſtinction to thoſe which belong to the light itſelf. The impreſſions made upon the eye by looking ſtedfaſtly at a particular colour are various, according to the ſingle colour or combination of colours in the object; and they continue for ſome time after the eye is withdrawn, and give a falſe colouring to other objects.

M. d'Arcy has contrived a machine for determining the duration of the effects of light.

ACCIPENSER, in ichthyology, the genus of fiſhes belonging to the claſs of amphibia, and order of nantes of Linnæus. See Syſtem of ICHTHYOLOGY.

ACCIPITER, the name of Linnæus's firſt order of birds. See Syſtem of ORNITHOLOGY.

ACCIPITER, a name given by the Romans to the hawk, and which, from its being carnivorous, they conſidered as a bird of bad omen:

> *Odimus Accipitrem, quia ſemper vivit in Armis.* OVID.

The hawk was worſhipped as a divinity by the inhabitants of Tentyra, an iſland in the Nilus; it was called by them, the image of the ſun; and on that account we find the ſun repreſented under the ſhape of an hawk.

ACCIPITRINA, in botany, the ſophia chirurgorum, or hawk-weed.

ACCLAMATION, a confuſed noiſe or ſhout of joy, by which the public expreſs their applauſe, eſteem, or approbation.

ACCLAMATION, in a more proper ſenſe, denotes words uttered with extraordinary vehemence. Acclamation uſually accompanied with applauſe, with which it is ſometimes confounded: though ought to be diſtinguiſhed; as acclamation given by the voice, applauſe by the hands; acclamation is alſo beſtowed on perſons abſent, applauſe only on thoſe preſent.

Acclamations are of various kinds; eccleſiaſtical, military, nuptial, ſenatorial, ſynodical, ſcholaſtic, theatrical, harmonical, &c. We meet with loud acclamations, muſical, and rythmical acclamations; acclamations of joy, reſpect, and even of reproach.

Acclamations were not unknown on the theatres in the earlieſt ages of the Roman commonwealth; but they were then no more than confuſed ſhouts. Afterwards they became a ſort of regular concerts. That mentioned by Phædrus, *lætare incolumis Roma ſalvo principe*, was made for Auguſtus. Nero was paſſionately fond of muſic, and took eſpecial care to improve and perfect the muſic of acclamations. Charmed with the harmony which the Alexandrians, who came to the games celebrated at Naples, had ſung his praiſes, he brought ſeveral over to inſtruct a number of youth, choſen from among the knights and people, in the different kinds of acclamations practiſed at Alexandria. Theſe continued in uſe as long as the reign of Theodoric. But the people did not always make a chorus; ſometimes there were two, who anſwered each other alternately: thus, when Nero played on the theatre, Burrhus and Seneca gave the ſignal by clapping, 5000 ſoldiers called Auguſtals, began to chaunt his praiſe, which the ſpectators were obliged to repeat. The whole was conducted by a muſicmaſter called Meſochorus or Pauſurious. The honour of acclamations was chiefly rendered to emperors, their children, and favourites; and to the magiſtrates who preſided at the games. Perſons of diſtinguiſhed merit alſo ſometimes received them, of which Quintilian gives us inſtances in Cato and Virgil. The moſt uſual forms were, *Feliciter, Longiorem vitam, Annos felices.* The actors themſelves, and thoſe who gained the prizes in the games of the circus, were not excluded the honour of acclamations.

To theatrical acclamations may be added thoſe of the ſoldiery and the people in time of triumph. The victorious ſoldiery accompanied their general to the capitol; and, among the verſes they ſung in his praiſe, frequently repeated, *Io Triumphe*, which the people anſwered in the ſame ſtrain.

The acclamations of the ſenate were ſomewhat more ſerious than the popular ones; but aroſe from the ſame principle, viz. a deſire of pleaſing the prince or his favourites; and aimed likewiſe at the ſame end, either to expreſs the general approbation and zeal of the company, or to congratulate him on his victories, or to make him new proteſtations of fidelity. Theſe acclamations were uſually given after a report made by ſome ſenator, to which the reſt all expreſſed their conſent by crying omnes, omnes: or elſe, æquum eſt, juſtum eſt. Sometimes they began with acclamations, and ſometimes ended with them without other debates. It was after this manner that all the elections and proclamations of emperors, made by the ſenate, were conducted; ſomething of which practice is ſtill retained at modern elections of kings and emperors, where *vivat rex, vive le roy*, and *long live the king*, are cuſtomary forms.

The Turks practiſe ſomething like this on the ſight of their emperors and grand vizirs to this day.

The acclamations in Greece which authors, poets, philoſophers, orators, &c. received, who recited their works in public, were held in great parade, in the moſt ſolemn places, as the capitol, temples, the Athenæum, and the houſes of great men. Invitations were ſent every where, in order to get the greater appearance. The chief care was, that the acclamations might be given with all the order and pomp poſſible. Men of fortune who pretended to wit, kept applauders in their ſervice, and lent them to their friends. Others endeavoured to gain them by preſents and treats. There were particular acclamations for the philoſophers, for orators, hiſtorians, and poets.

The acclamation which the ſpectators honoured the victories of the athletæ were a natural conſequence of the impetuous motions which attended the gymnaſtic games. The cries and acclamations of the people ſometimes expreſſing their compaſſion and joy, ſometimes their horror and diſguſt, are ſtrongly painted by different poets and orators.

Acclamations made alſo a part of the ceremony of marriage. They were uſed for the omen's ſake; being the Læta Omina, ſometimes ſpoken of before marriage in Roman writers.

Acclamations, at firſt practiſed in the theatre, and paſſing thence to the ſenate, &c. were in proceſs of time received into the acts of councils, and the ordinary aſſemblies of the church. The people expreſſed their approbation of the preacher variouſly; the more uſual forms were, Orthodox! Third Apoſtle, &c. Theſe acclamations being ſometimes carried to exceſs, and often miſplaced, were frequently prohibited by the ancient doctors, and at length abrogated; though they appear to have been in ſome uſe as low as the time of St. Bernard.

ACCLIVUS, in anatomy, a muſcle, otherwiſe called obliquus aſcendens.

Acclivity, the riſe or ſlope of a hill, uſuall yoppoſed to the declivity or deſcent of a hill. In fortification it ſignifies the talus of the rampart.

ACCOLA generally implies a perſon reſident near a certain place: which, among the Romans, was in contradiſtinction to the incola, or reſidents in a certain place.

ACCOLADE, a ceremony anciently uſed in the conferring of knighthood.

When William the Conqueror conferred the honour of knighthood on his ſon Henry, it was given with the naked fiſt; but was afterwards changed into a blow, with the flat part of the ſword on the ſhoulder of the knight.

ACCOLEE, ſometimes ſynonymous with Accolade, and uſed in various ſenſes in heraldry: ſometimes it is applied to two things joined; at other times, to animals with crowns, or collars about their necks, and, laſtly, to kews, battons, maces, ſwords, &c. placed ſaltierwiſe behind the ſhield.

Accommodation, the application of one thing, by analogy, to another; or the making two or more things agree with one another.

A prophecy of Scripture is ſaid to be fulfilled various ways; properly, as when a thing foretold comes to paſs; and improperly, or by way of accommodation, when an event happens to any place or people, like to what fell out ſome time before to another. Thus, the words of Iſaiah, ſpoken to thoſe of his own time, are ſaid to be fulfilled in thoſe who lived in our Saviour's; and are accommodated to them: "Ye hypocrites, well did Iſaiah's prophecy of you, &c." which ſame words St. Paul afterwards accommodates to the Jews of his time.

The primitive church accommodated multitudes of Jewiſh, and even heathen ceremonies and practices, to Chriſtian purpoſes; but the Jews had before done the ſame by the Gentiles: ſome will even have circumciſion, the tabernacle, brazen ſerpent, &c. to have been originally of Egyptian uſe, and only accommodated by Moſes to the purpoſes of Judaiſm.

ACCOMPANIMENT, ſomething attending or added as a circumſtance to another either by way of ornament, or for the ſake of ſymmetry.

Accompaniment, in muſic, denotes the inſtruments which accompany a voice, in order to ſuſtain it, as well as to make the muſic more full. The accompaniment is uſed in recitative, as well as in ſong; on the ſtage, as well as in the choir, &c.

Accompaniment, in painting, denotes ſuch objects as are added, by way of ornament, as dogs, guns, game, &c. in a hunting-piece.

Accompaniment, in heraldry, any thing added to a ſhield by way of ornament; as the belt, mantling, ſupporters, &c. It is alſo applied to ſeveral bearings about a principal one; as a ſatlier, bend, feſs, chevron, &c.

ACCOMPLICE, one concerned in any bad act; or is privy in the ſame deſign or crime with another, and is ſynonimous with acceſſary.

ACCOMPLISHMENT, the entire execution or fulfilling of any thing.

Accomplishment is principally uſed in ſpeaking of events foretold by the Jewiſh prophets in the Old Teſtament, and fulfilled under the New. We ſay a literal accompliſhment, a ſpiritual accompliſhment, a ſingle accompliſhment, a double accompliſhment, a Jewiſh accompliſhment, a Chriſtian, or a heathen accompliſhment. The ſame prophecy is ſometimes accompliſhed in all, or in ſeveral of thoſe different ways. Thus, of ſome of the prophecies of the Old Teſtament, the Jews find a literal accompliſhment in their own hiſtory, about the time when the prophecy was given: the Chriſtians find another in Chriſt, or the earlieſt days of the church; the heathens another, in ſome of their emperors; the Mahometans another, in their legiſlator, &c. There are two principal ways of accompliſhing a prophecy; directly, and by accommodation.

Accomplishment is alſo uſed for any mental or perſonal endowment.

ACCORD, in painting, is the harmony that reigns among the lights and ſhades of a picture.

ACCOUNT, or Accompt, in a general ſenſe, implies a computation by numbers. It is alſo uſed collectively, for the ſeveral books or regiſters which merchants keep of their affairs or negotiations. See Syſtem of Book-Keeping.

Chamber accounts, in France, the ſame as our court exchequer.

Account, in chronology, we compute for a particular period. Thus we ſay the Julian account, the Gregorian account, &c. which in aſtronomical reckoning we call the new and old ſtyle.

ACCOUNTANT, or Accomptant, a perſon well verſed in accounts; whether employed by private perſons, or public companies.

ACCOUNTANTSHIP, the art of keeping and balancing accounts.

ACCOUNTANT-General, a new officer in the court of Chancery appointed by act of parliament to receive all monies lodged in court inſtead of the maſters, and convey the ſame to the bank of England for ſecurity.

ACCOUTREMENT, a term applied to the furniture of a ſoldier, knight, or gentleman.

ACCRETION, in phyſics, the increaſe or growth of an organical body, by the acceſſion of new parts.

Accretion, among civilians, the property acquired in a vague for unoccupied thing, by its adhering to or following another already occupied: thus, if a legacy be left to two perſons, one of whom dies before the teſtator, the legacy devolves to the ſurvivor by right of accretion.

ACCROACHING, the ſame as Incroaching; to prohibit, which a law was made 25 Ed. III. cap. 2. It alſo comprehended the aſpiring of uſurpers to regal dignity, and had various interpretations relative to treaſonable conſtructions.

ACCROCHE, in heraldry, denotes a thing being hooked with another.

ACCRUE, in law, ſignifies ſomething that accedes to, or follows the property of another part or perſon. Thus money as principal incurs intereſt to accrue due on it, as the legal profit of the proprietor.

ACCUBATION, a poſture of the body, between ſitting and lying. The word comes from the Latin *accubare*, compounded of *ad*, to, and *cubo*, I lie down. Accubation, or Accubitus, was the table-poſture of the Greeks and Romans; whence we find the words particularly uſed for the lying, or rather ſitting, down to meat. The Greeks introduced this poſture. The Romans, during the frugal ages of the republic, were ſtrangers to it: but as luxury got more univerſal, this poſture came to be adopted, at leaſt by the men; for as to women, it was reputed an indecency in them to lie down among the men. Children did not lie down, ſervants, ſoldiers, nor perſons of meaner condition; but took their meals ſitting, as a poſture leſs indulgent. The Roman manner of diſpoſing themſelves at table was this: a low round table was placed in the cœnaculum, or dining-room, and, about this, uſually three, ſometimes only two, beds or couches; according to the number, it was called biclinium, or triclinium. Theſe were covered with a ſort of bed-clothes, richer or plainer, according to the quality of the perſon, and furniſhed with quilts and pillows, that the gueſts might lie the more commodiouſly. There were uſually three perſons on each bed. In eating, they lay down on their left ſides, with their heads reſting on the pillows, or rather on their elbows.

ACCUBITOR, an ancient officer of the emperors of Conſtantinople, whoſe buſineſs was to lie near the emperor. He was the head of the youth of the bed-chamber, and had the cubicularius and procubitor under him.

ACCUMULATION, in a general ſenſe, the act of heaping or amaſſing things together. Among lawyers, it is uſed in ſpeaking of the concurrence of ſeveral titles to the ſame thing, or of ſeveral circumſtances to the ſame proof.

Accumulation *of Degrees*, in an univerſity, is the taking ſeveral of them together, or at ſmaller intervals, than is allowed by the rules of the univerſity.

ACCURSED, ſomething that lies under a curſe, or ſentence of excommunication.

In the Jewiſh idiom, accurſed and crucified were ſynonymous. Among them, every one was accounted accurſed, who died on a tree. This ſerves to explain the difficult paſſage in Rom. ix. 3. where the apoſtle Paul wiſhes himſelf accurſed after the manner of Chriſt, i. e. crucified, if happily he might by ſuch a death ſave his countrymen.

ACCUSATION, the charging any perſon with a criminal action, either in one's own name, or in that of the public. The word is compounded of *ad*, to, and *cauſari*, to plead.

Writers on politics treat of the benefit and the inconveniences of public accuſations. Various arguments are alleged, both for the encouragement and diſcouragement of accuſations againſt great men. Nothing, according to Machiavel, tends more to the preſervation of a ſtate, than frequent accuſations of perſons truſted with the adminiſtration of public affairs. This, accordingly, was ſtrictly obſerved by the Romans, in the inſtances of Camillus, accuſed of corruption by Manlius Capitolinus, &c. accuſations, however, in the judgment of the ſame author, are not more beneficial than calumnies are pernicious; which is alſo confirmed by the practice of the Romans. Manlius, not being able to make good his charge againſt Camillus, was caſt into priſon.

By the Roman law, there was no public accuſer for public crimes; every private perſon, whether intereſted in the crime or not, might accuſe, and proſecute the accuſed to puniſhment, or abſolution. Cato, the moſt innocent perſon of his age, had been accuſed 42 times, and as often abſolved. But the accuſation of private crimes was never received but from the mouths of thoſe who were immediately intereſted in them: but the huſband could accuſe his wife of adultery.

In the French law, none but the procureur general, or his deputies, can form an accuſation, except for high-treaſon and coining, where accuſation is open to every body. In other crimes, private perſons can only act the part of denouncers, and demand reparation for the offence, with damages.

In Britain, by Magna Charta, no man ſhall be impriſoned or condemned on any accuſation, without trial by his peers, or the law; none ſhall be vexed with any accuſation, but according to the law of the land; and no man may be moleſted by petition to the king, &c. unleſs it be by indictment or preſentment of lawful men, or by proceſs at common law. Promoters of ſuggeſtion are to find ſurety to purſue them; and if they do not make them good ſhall pay damages to the party accuſed, and alſo a fine to the king. No perſon is obliged to anſwer upon oath to a queſtion whereby he may accuſe himſelf of any crime.

ACCUSATIVE, in the Latin grammar, is the fourth caſe of nouns, and ſignifies the relation of the noun on which the action implied in the verb terminates; and hence, in ſuch languages as have caſes, theſe nouns have a particular termination, called *accuſative*: as, *Auguſtus vicit Antonium*, Auguſtus vanquiſhed Antony. Here Antonium is the noun, on which the action implied in the verb *vicit* terminates; and, therefore, muſt have the accuſative termination. In Engliſh, we have nothing to diſtinguiſh this caſe from the *nominative*; but as we ordinarily place words in their natural order, it is eaſily diſcovered; the *nominative* conſtantly preceding, and the *accuſative* following the verb. Thus, when we ſay, the prince loves the princeſs, and the princeſs loves the prince: the prince is the *nominative* in the firſt, and the *accuſative* in the laſt; and the princeſs the *accuſative* in the firſt, and the *nominative* in the ſecond.

ACENTETUM, or ACANTETA, in natural hiſtory, a name given by the ancients to the pureſt and fineſt kind of rock-cryſtal: they uſed the cryſtal various ways; ſometimes engraving on it, and ſometimes forming it into vaſes and cups, which were held next in great eſtimation.

ACEPHALI, or ACEPHALITÆ, a term applied to ſeveral ſects who refuſed to follow ſome noted leader. Thus the perſons who refuſed to follow either John of Antioch, or St. Cyril, in a diſpute that happened in the council of Epheſus, were termed *acephali*, without a head or leader. Such biſhops, alſo, as were exempt from the juriſdiction and diſcipline of their patriarch, were ſtyled *acephali*.

ACEPHALOUS, or ACEPHALUS, in a general ſenſe; without a head.

ACEPHALUS, an obſolete term for the tænia, or tape-worm, which was long ſuppoſed to be acephalous. The firſt who gave it a head was Tulpius; and after him, Fehr: the former even makes it biceps, or two headed.

ACEPHALUS is alſo uſed in poetry, to expreſs a verſe defective in the beginning.

ACER, the MAPLE, or SYCAMORE TREE; a genus of the monœcia order, belonging to the polygamia claſs of plants; and ranking under the 23d natural order, Trihilatæ.

ACERATES, ſignifies an unmixed, or uncorrupted ſtate, whether of body or mind.

ACERB, a ſour rough aſtringency of taſte, ſuch as that of unripe fruit.

ACERIDES, plaſters made without wax.

ACERINA, in ichthyology, a name given by Pliny and other of the old naturaliſts, to the fiſh we at this time call the ruffe.

ACEROSUS, a term denoting the browneſt and coarſeſt ſort of bread.

ACERRA, in antiquity, an altar, erected among the Romans, near the bed of a perſon deceaſed, on which his friends daily offered incenſe till his burial. The real intention probably was to overcome any offenſive ſmell that might ariſe about the corpſe. The Chineſe have ſtill a cuſtom like this: they erect an altar to the deceaſed in a room hung with mourning; and place an image of the dead perſon on the altar, to which every one that approaches it bows four times, and offers oblations and perfumes.

The acerra alſo ſignified a little pot, wherein were put the incenſe and perfumes to be burnt on the altars of the gods and before the dead. It appears to have been the ſame with what was otherwiſe called thuribulum, and pyxis.

We find mention of acerræ, in the ancient church. The Jews had alſo their acerræ, in our verſion rendered cenſers; and the Romaniſts ſtill retain them under the name of incenſe-pots. In Roman writers, we frequently meet with plena acerra, a full acerra: to underſtand which, it is to be obſerved, that people were obliged to offer incenſe in proportion to their eſtate and condition: the rich in larger quantities, the poor only a few grains; the former poured out acerras full on the altar, the latter took out two or three bits with their fingers.

ACESCENT, a word uſed to denote any thing which is turning ſour, or is ſlightly acid. It is only applied properly to the former of theſe two meanings. The ſecond may be expreſſed by either of the two words, acidulous or ſub-acid.

ACESTA, curable diſtempers.

ACESTIDES, the conductors of braſs founderies to confine the air, ſo as to cauſe it to aſcend rapidly in a narrow funnel, by which it increaſed the heat of the furnace.

ACESTIS, a fictitious ſort of chryſocolla, made of Cyprian verdigreaſe, nitre and urine.

ACETABULUM, in antiquity, a ſmall vaſe, or cup, uſed to ſerve up articles proper for ſervice at tables, much after the manner of our ſalts and vinegar cruets.

ACETABULUM, in anatomy, a cavity in any bone for receiving the protuberant head of another, and thereby forming that ſpecies of articulation called Enarthroſis.

ACETABULUM, in botany, the name of a genus of the cryptogamia fungi, of Linnæus, the leaves of which reſemble a cup.

ACETARY, in the anatomy of plants, this term is applied to a pulpy ſubſtance in certain fruits, e. g. the pear, which is incloſed in a congeries of ſmall calculous bodies towards the baſe of the fruit, and is always of an acid taſte.

ACETIFICATION, in chemiſtry, the proceſs by which vinegar is made, which is done ſolely by expoſing vicious liquors in open veſſels, and may with propriety be called a ſpecies of fermentation, as the rarefaction of the ſaline particles is the chief point to be attended to.

ACETOSA, ſorrel; by Linnæus joined to the genus of dock, under the title of rumex.

ACETOSELLA, in botany, a ſpecies of oxalis.

ACETOUS, an epithet applied to ſuch ſubſtances as are ſour, or partake of the nature of vinegar.

ACETUM, vinegar, the vegetable acid of the chemiſts.

ACHAC, in ornithology, a bird very common in the Philippine iſlands.

ACHÆANS, a name given to the Grecians by ancient authors, alluding to the country they poſſeſſed.

ACHAIÆ PRESBYTERI, the preſbyters of Achaia, who are ſaid to have been preſent at the martyrdom of St. Andrew.

ACHALALACTLI, in ornithology, a ſpecies of king's fiſher, a bird remarkable for having a chain or ring of ſilver whiteneſs round its neck. It is common about the lakes and rivers of Mexico.

ACHANE, a Perſian corn meaſure, containing about 45 Attic medimni.

ACHAOVA, a medicinal plant, reſembling camomile. It is uſeful in many feveriſh diſorders.

ACHARISTON, a compoſition in medicine, of ſingular efficacy.

ACHAT, in law, implies a purchaſe or bargain: hence purveyors are called achators.

ACHATES, in mineralogy, the agate ſtone.

ACHE, or ACH, a painful ſenſation in the head, limbs, or any part of the body, occaſioned by chronic diſeaſes.

ACHEMENIS, an herb, with which Pliny relates had the property of exciting terror.

ACHERNER, in aſtronomy, a ſtar of the firſt magnitude, in the conſtellation Eridanus, whoſe longitude is 10° 31′ of Pices, and lat. 59° 18′ S. therefore inviſible in our latitude.

ACHEREST, a corn meaſure of about eight buſhels, anciently uſed in the northern counties of England.

ACHETA, in entomology, the ſame as cicada, of the order of hemiptera. See Syſtem of ENTOMOLOGY.

ACHIA, an Eaſt India pickle of the ſpecies of ſugar-cane.

ACHIAR, a general name for Eaſt Indian pickles imported into Europe.

ACHIÆNUS, in antiquity, implied a two years old deer.

ACHICOLUM, in antiquity, a medicated bath.

ACHILLEA, in medicine, the ſanguis draconis, or dragon's blood.

ACHILLÆA, YARROW, MILFOIL, NOSEBLEED, or SNEEZEWORT; a genus of the order of the polygamia ſuperflua, belonging to the ſyngeneſia claſs of plants. The natural order to which it belongs is the 49th Compoſitæ diſcoides. For its characters ſee Syſtem of BOTANY.

ACHILLEID, ACHILLEIS, a celebrated poem of Statius, in which that author propoſed to deliver the whole life and exploits of Achilles; but being prevented by death, he has only treated of the infancy and education of his hero.

ACHILLES, a name given by ſchools to the principal argument alledged by each ſect of philoſophers in behalf of their ſyſtem. In this ſenſe we ſay, this is his Achilles, that is, his maſter-proof, alluding to the ſtrength and importance of Achilles among the Greeks.

Tendo ACHILLES, in anatomy, is a ſtrong tendonous cord, formed by the tendons of ſeveral muſcles, and inſerted into the os calcis. It has its name from the fatal wound Achilles is ſaid to have received in that part from Paris the ſon of Priam.

ACHIOTTE, or ACHIOTL, a Brazilian name for a red drug imported from America.

ACHIOTTE is uſed in dying, and in the preparation of chocolate. It is the ſame with the ſubſtance more uſually known by the name of *arnotto*; called by the Dutch *orleane*, and by the French *roucou*. In phyſic, it is a preſervative againſt retention of urine.

ACHIROPŒTOS, a name given by the ancient writers to certain miraculous pictures of Jeſus Chriſt and the Virgin Mary, ſuppoſed to have been made without hands. The moſt celebrated of theſe is the picture of Chriſt, preſerved in the church of St. John Lateran at Rome, ſaid to have been begun by St. Luke, but finiſhed by the miniſtry of angels.

ACHLYS, in medicine, a darkneſs or dimneſs of ſight, ariſing from a ſmall cicatricula on the pupil, occaſioned by a ſuperficial ulcer on the cornea.

ACHNE, in ancient authors, implied various things, ſuch as, froth; the white mucilage in the eyes of ſick perſons; white mucus in the fauces, thrown up by the lungs; chaff, huſks of fruit, &c.

ACHOR in medicine, a ſpecies of herpes.

ACHOR, in mythology, the god of flies, to whom, according to Pliny, the inhabitants of Cyrene ſacrfiiced, in order to obtain deliverance from thoſe inſects and the diſorders occaſioned by them.

ACHRAS, or Sapota Plum, a genus of the monogynia order, belonging to the hexandria claſs of plants, and ranking in the 43d natural order Dumoſæ.

There are four ſpecies, all natives of the Weſt Indies. The two principal ſorts are, 1ſt, the ſapota, with oblong leaves and ſmooth turbinated fruit. 2. The mamoſa, with ſpear-ſhaped leaves, and large oval fruit.

The firſt is common in the iſlands of Cuba and St. Domingo, but not in the Britiſh iſles. The ſecond is common in Jamaica, Barbadoes, and all the Weſt India iſlands, where it grows as a garden plant, to the height of 40 feet, having a ſtraight trunk, covered with aſh-coloured bark.

The ſtones of this fruit taken in emulſion are reckoned good againſt the gravel. No ſpecies of the achras can be preſerved in this country, except in the warmeſt ſtoves.

ACHRAT, in the Arabic, ſignifies life eternal, a term commonly made uſe of in the Turkiſh or Mahometan worſhip. This word is always oppoſed to *dinia*, the world, or preſent life. Alcoran, Ch. Houd.

Achrat, to the Perſian ſect of Ali, ſignifies, khaneh ferdai, i. e. the habitation of to-morrow; figuratively implying, that this life is but of one day's continuance; and eternity lies beyond it.

ACHROMATIC, ſignifies a want of colour. The word is Greek, compounded of *a*, privative, and *χϱομα*, colour.

ACHROMATIC Teleſcope, a teleſcope contrived to remedy the aberration in colours; for its principles and properties ſee Syſtem of Optics.

ACHTELING, a German liquid meaſure; 32 making a heemor; and 4 ſciltins make an achteling.

ACHTENDEELING, or Achteling, a corn meaſure uſed in the province of Holland.

ACHY, a ſpecies of caſſia that grows in Arabia.

ACHYRANTHES, in botany, a genus of the pentandria order, belonging to the monogynia claſs of plants, aſſociating with the miſcellaneæ in the 54th natural order. There are eight ſpecies enumerated, and two more are added; however, the character of the genus does not agree in them all. They are all natives of India except the amaranthus, which is cultivated in botanical gardens. It grows to the height of three feet; flowers in July, and ſeeds in September.

ACHYRONIA, in botany, a name given by ſome authors to the aſpalathus of Linnæus.

ACHYROPHORUS, in botany, the ſame as the hypochæris.

ACIA, in Roman ſurgery, implied an eaſy manner of placing a roller over a wound.

ACICANTHERA, in botany, the trivial name of a ſpecies of rhexia.

ACICOCA, a Peruvian plant, which has the properties of the herb paraguay.

ACICULÆ, the ſmall pikes or prickles of fiſhes, the hedgehog, &c. &c.

ACIDITY, that quality which renders bodies acid.

ACIDOTON, in botany, the trivial name of a ſpecies of adelia.

ACIDS derive their name from the word *acere*, to be ſharp, and are always of a ſour ſalt taſte.

Acids, in chemiſtry, the name by which one of the general claſſes of ſalt are diſtinguiſhed. For the characteriſtic marks, ſee ſyſtem of Chemistry.

Acids derived from particular names, are regularly arranged to come under their proper heads alphabetically.

Acids, in medicine, imply ſuch liquids as have an acid quality, as ſpirits of vitriol, vinegar, &c. &c.

ACIDULÆ, cold mineral waters which contain a briſk ſpirit; in oppoſition to thoſe which are hot, called, thermæ.

ACIDULATED, a term applied to medicines which have an acid in their compoſition.

ACIDULOUS, denotes a thing that is ſlightly acid; it is ſynonimous with the word ſub-acid.

ACIDUM *Ætherium*, *Aluminoſum*, *Catholicum*, *Primigenium*, *Sulphureum*, ſeverally imply, ſpirit of vitriol.

Acidum *Aereum*, ſynonimous with fixed air.

Acidum *Pingue*, an imaginary acid, which ſome German chemiſts ſuppoſed to be contained in fire, and by combining with alkalis, lime, &c. to give them their cauſtic properties: an effect which is found certainly to depend on the loſs of their fixed air.

ACINACES, in antiquity, a Perſian ſcimetar worn by chieftains, or principal captains of the military order.

ACINARIA, a botanic name for vaccinia paluſtria, or marſh whortle-berries.

ACINESIA, in medicine, the immobility of the whole of the body, or any part of it; as in the palſy, epilepſy, ſwooning, apoplexy, &c.

ACINI, in botany, ſmall grains or berries growing in bunches; as grapes, elder-berries, &c.

ACINODENDRON, or Acinodendrum, in botany, the trivial name of the thymus, in the claſs and order of didynamia gymnoſpermia.

ACINOS, ſtone, or wild baſil.

ACINUS, ſynonimous with Acini, but properly, only ſignifies the grape.

ACITLI, in ornithology, the lepus aqueus, or water hare.

ACKNOWLEDGMENT, in a general ſenſe, implies a confeſſion of ſomething had, done or received; but more particularly denotes the reward of ſome ſervice, or the grateful requital of a favour received.

Acknowledgment *Money*, a gift preſented to a new landlord, on the demiſe of the old one.

ACLIDES, in Roman antiquity, a kind of miſſive weapon, with a thong affixed to it, by which it might be drawn back after caſting it from the hand; moſt authors deſcribe it as a dart or javelin; but Scaliger ſays, it was globular, full of ſpikes, with a ſlender wood ſtem, to poiſe it by.

ACLOWA, in botany, a barbarous name of a ſpecies of colutea. The natives of Guinea uſe it to cure the itch, by rubbing it as we do unguents.

ACME, the top, or height of any thing. It is uſually applied to the maturity of an animal, juſt before it begins to decline. Phyſicians ſignify by it the height or worſt ſtage of a diſeaſe. It is alſo uſed to ſignify the prime or beſt part of a thing.

ACMELLA, or Achamella, in botany, the trivial name of a ſpecies of ſpilanthus.

ACNE, a ſmall pimple, or hard tubercle on the face.

ACNIDA, or Virginian Hemp, a genus of the dioecia order, and petandria claſs, in botany. As it is not applied to any uſe, the culture neceſſary to raiſe it is here unneceſſary; but in general terms, it may be growed as the European hemp.

ACNUA, amongſt the ancient Romans, ſignified a certain determinate meaſure of land, about a quarter of an acre Engliſh ſtatute meaſure.

ACNUM, in the language of the Alcoran, implies ſubſtance, or hypoſtaſis. The Turks and other Mahometans uſe it in prayer to ſignify a plurality in the Deity, yet they deny it to be a tenet of their church. D'Herbelot, Biblioth. Orient.

ACO, in ichthyology, a Mediterranean fiſh, called aquo, ſarachus, and ſarachinus.

ACOEMETÆ, or Acoemeti, in eccleſiaſtical hiſtory, ſignified the Alexandrian monks, a ſect ſet up by one Alexander at Conſtantinople, the beginning of the fifth century; they grounded their doctrine on the precept of St. Paul "to pray without ceaſing"; ſo that a conſtant ſucceſſion of prayer was kept up day and night by ſome of the members of the fraternity.

There are a kind of *acoemetæ* ſtill ſubſiſting in the Romiſh church; for ſo the religious of the holy ſacrament may properly be ſtiled, in that they keep up perpetual adoration; ſome or other of them praying before the ſacrament day and night.

ACOLCHICHI, in ornithology, a Mexican bird, called by Nieremberg, peterophœnicus Indiarum.

ACOLIN, a ſpecies of the partridge kind, a native of the Weſt India iſlands.

ACOLUTHISTS, Acolythists, or Acoluthi, an inferior order of clergy in the primitive church, among the Latins, and ranked next to the ſub-deacons. At their ordination, the archdeacon puts into their hands a candleſtick, with a taper, giving them to underſtand, they were to light candles for the church; as alſo an empty pitcher, to ſignify that they were to furniſh wine for the euchariſt. Some think they had another office, which was, to accompany and attend the biſhop, as alſo to bury the dead. The word comes from the Greek, *ακολȣθος*, a young ſervant. Heſychius.

Acoluthists, in philoſophy, ſignified a ſect of ſtoics, who never varied their principles, or turned aſide from the precepts of their doctrine.

ACOLYTHIA, in the Greek church, denotes the office of divine ſervice; or the prayers, ceremonies, hymns, &c. whereof the Greek ſervice is compoſed.

ACON, an inſtrument uſed in ancient exerciſes, like the diſcus.

Acon, a ſynonome of the knight's hoſpitallers.

ACONCROBA, in botany, the indigenous name of a plant which grows wild in Guinea, and is in great eſteem among the natives for its virtues in the ſmall-pox. They give an infuſion of it in wine. The leaves of this plant are opake, and as ſtiff as thoſe of the philyrea; they grow in pairs, and ſtand on ſhort foot-ſtalks; they are ſmall at each end, and broad in the middle; and the largeſt of them are about three inches in length, and an inch and quarter in breadth in the middle. Like thoſe of our bay, they are of a duſky colour on the upper ſide, and of a pale green underneath.

ACONE, in natural hiſtory, a whetſtone or hone, anciently called coticula by the Romans. It ſignifies alſo a mortar for levigation.

ACONITE, in botany, a plant famous among the ancients for having the quality of a poiſon and the properties of a remedy. Arrows dipt in its juice where they wound are ſaid to prove mortal. The Indians uſed aconite, corrected in cows urine, with good ſucceſs againſt fevers.

ACONITI, in antiquity, an appellation given to ſome of the athletæ, but differently interpreted. Mercurialis underſtands it of thoſe who only anointed their bodies with oil, but did not ſmear themſelves over with duſt, as was the uſual practice.

ACONITON, implies an unlined veſſel, or any thing that remains unfiniſhed within ſide.

ACONITUM, ACONITE, WOLFSBANE, or MONKSHOOD; a genus of the trigynia order, belonging to the polyandria claſs of plants. In the natural order, it aſſociates with the multiſiliquæ, 26. On account of the poiſonous qualities of monkſhood, no ſpecies of it ſhould be planted where children have acceſs, leſt they ſhould ſuffer by putting the leaves or flowers in their mouths, or rubbing them about their eyes; for the juice of the leaves will occaſion great diſorder by being only rubbed upon very tender fleſh; and the farina of the flowers, when blown into the eyes, cauſes them to ſwell greatly. For the generic characters, ſee Syſtem of BOTANY.

ACONTIAS, in zoology, an obſolete name of the anguis jaculis, or dart-ſnake, belonging to the order of amphibia ſerpentes.

ACONTIUM, in Grecian antiquity, a kind of dart or javelin, reſembling the Roman pilum.

ACOPA, in botany, the trifolium paludoſum, or buck bean.

ACOPA, in medicine, denotes a remedy againſt ſtrains of the body, loins, or limbs. It alſo implies ſoft cerates made uſe of for tumors.

ACOPIS, a foſſile ſalt, uſed by the ancients to anoint the limbs after fatigue.

ACOPIS, alſo ſignifies a valuable cryſtal.

ACOPOS, the laburnum, or baſe trefoil, ſome call the bean trefoil by this name.

ACOR, ſignifies acidity or ſourneſs.

ACORDINA, the Indian tutty.

ACORN, in natural hiſtory, the fruit of the oak-tree.

ACORN, in ſea language, a little ornamental piece of wood, faſhioned like a cone, and fixed on the uppermoſt point of the ſpindle, above the vane, on the maſt-head. It is uſed to keep the vane from being blown off from the ſpindle in a whirlwind, or when the ſhip leans much to one ſide under ſail.

ACORUS, CALAMUS AROMATICUS, SWEET FLAG, or SWEET RUSH; a genus of the monogynia order, belonging to the hexandria claſs of plants; and ranking in the ſecond natural order, Piperitæ. For the genuine characters, ſee Syſtem of BOTANY.

ACORUS, in the materia medica, a name ſometimes given to the great galangal.

ACORUS, or ACORI, in natural hiſtory, blue coral. The true ſort is very ſcarce; ſome, however, is fiſhed on the coaſts of Africa, particularly from Rio del Re to the river of the Camarones. This coral is part of the merchandiſe which the Dutch trade for with the Camarones: that of the kingdom of Benin is alſo very much eſteemed. It grows in form of a tree on a rocky bottom.

ACOUSMATICI, ſometimes alſo called Acouſtici, in Grecian antiquity, ſuch of the diſciples of Pythagoras as had not completed their five years probation.

ACOUSTIC, in general, denotes any thing that relates to the ear, or the doctrine of ſounds. It is particularly applied to inſtruments uſed by thoſe who are dull of hearing.

ACOUSTIC *Duſt*, in anatomy, the ſame with meatus auditorius, or the external paſſage of the ear.

ACOUSTIC *Inſtrument*, or auricular tube, to aſſiſt the hearing.

ACOUSTIC *Veſſels*, in the ancient, theatres were a kind of veſſels made of braſs, ſhaped in the bell faſhion, which being of all tones within the pitch of the voice or even of inſtruments, rendered the ſounds more audible, ſo that the actors could be heard through all parts of the theatres, which were not leſs than 400 feet in diameter.

ACOUSTIC *Diſciples*, among the ancient Pythagoreans, thoſe more commonly called Acouſmatici.

A NEW SYSTEM of ACOUSTICS, or PHONICS.

THIS ſcience comprehends the doctrine of ſounds, and is uſually divided into two parts; namely, diacouſtics, which explains thoſe ſounds that come directly from a ſonorous body to the ear; and catacouſtics, which treats of reflected ſounds; but ſuch diſtinction does not appear neceſſary, as the whole Syſtem may well be comprehended under one head, as will be clearly ſhewn from what follows:

DEFINITION I.

All ſounds are conveyed to us on the boſom of the air, whether they float upon it, or are propelled forward in it, otherwiſe there would be no ſound at all. Let the air be exhauſted from a receiver, and a bell ſhall emit no ſound when rung in the void; for, as the air continues to grow leſs denſe, the ſound dies away in proportion, ſo that at laſt its ſtrongeſt vibrations are almoſt totally ſilent.

Thus air is a vehicle for ſound. However, we muſt not, with ſome philoſophers, aſſert, that it is the only vehicle; that, if there were no air, we ſhould have no ſounds whatever: for it is found by trial, that ſounds are conveyed through water almoſt with the ſame facility with which they move through air. A bell rung in water returns a tone as diſtinct as if rung in the air. This was obſerved by Derham, who alſo remarked the tone came a quarter deeper. From hence, it would ſeem not to be very material in the propagation of ſounds, whether the fluid which conveys them be elaſtic or otherwiſe. Water, which, of all ſubſtances that we know, has the leaſt elaſticity, yet ſerves to carry them forward; and if we make allowance for the difference of its denſity, perhaps the ſounds move in it with a proportional rapidity to what they are found to do in the elaſtic fluid of air.

It is neceſſary to obſerve, that whether the fluid which conveys the note be elaſtic or non-elaſtic, whatever ſound we hear is produced by a ſtroke, which the ſounding body makes againſt the fluid, whether air or water. The fluid being ſtruck upon, carries the impreſſion forward to the ear, and there produces its ſenſation. Sound is nothing more than the impreſſion made by elaſtic body upon the air or water, and this impreſſion carried along by either fluid to the organ of hearing. Whether the ſound is diffuſed into the air, in circle beyond circle, like the waves of water when we diſturb the ſmoothneſs of its ſurface by dropping in a ſtone; or whether it travels along, like rays diffuſed from a centre, ſomewhat in the ſwift manner that electricity runs along a rod of iron, are queſtions which have divided the learned.

Sir Iſaac Newton has explained the progreſſion of ſound by an undulatory, or rather a vermicular, motion in the parts of the air. If we have an exact idea of the crawling of ſome inſects, we ſhall have a tolerable notion of the progreſſion of ſound upon this hypotheſis. The inſect, for inſtance, in its motion, firſt carries its contractions from the hinder part, in order to throw its fore-part to the proper diſtance, then it carries its contractions from the fore-part to the hinder to bring that forward. Something ſimilar to this is the motion of the air when ſtruck upon by a ſounding body.

All who have remarked the tone of a bell, while its ſounds are decaying away, muſt have an idea of the *pulſes* of ſound, which, according to Newton, are formed by the air's alternate progreſſion and receſſion. As to the velocity with which ſounds travel, Newton determines, by the moſt difficult calculation that can be imagined, to be in proportion to the thickneſs of the parts of the air, and the diſtance of theſe parts from each other. From hence he goes on to prove, that each little part moves backward and forward like a pendulum; and from thence he proceeds to demonſtrate, that if the atmoſphere were of the ſame denſity every where as at the ſurface of the earth, in ſuch caſe, a pendulum, that reached from its higheſt ſurface down to the ſurface of the earth, would by its vibrations diſcover to us the proportion of the velocity with which ſounds travel. The velocity with which each pulſe would move, he ſhows, would be as much greater than the velocity of ſuch a pendulum ſwinging with one complete vibration, as the circumference of a circle is greater than the diameter. From hence he calculates, that the motion of ſound will be 979 feet in one ſecond. But this not being conſonant to experience, he takes in another conſideration, which deſtroys entirely the force of his former demonſtration, namely, vapours in the air; and then finds the motion of ſound to be 1142 feet in one ſecond, or near 13 miles in a minute: a proportion which experience had eſtabliſhed nearly before.

Another theory advanced is, that every ſound may be conſidered as driven off from the ſounding body in ſtraight lines, and impreſſed upon the air in one direction only: but whatever impreſſion is made upon a fluid in one direction, is diffuſed upon its ſurface into all directions; ſo that the ſound firſt driven directly forward with a very ſwiſt motion, reſembling the velocity with which we know electricity flies from one end of a line to another.

Now, as to the pulſes, or cloſe ſhakes as the muſicians expreſs it, which a ſounding body is known to make, each pulſe is itſelf a diſtinct and perfect ſound, and the interval between every two pulſes is profoundly ſilent. Continuity of ſound from the ſame body is only a deception of the hearing; for as each diſtinct ſound ſucceeds at very ſmall intervals, the organ has no time to tranſmit its images with equal ſwiftneſs to the mind, and the interval is thus loſt to ſenſe: juſt as in ſeeing a flaming torch, if flared round in a circle, it appears as a ring of fire. In this manner a beaten drum, at ſome ſmall diſtance, preſents us with the idea of continuing ſound. When children run with their ſticks along a rail, a continuing ſound is thus repreſented, though it need ſcarce be obſerved that the ſtroke againſt each rail is perfectly diſtinct and inſulated.

All bodies whatſoever that are ſtruck, return more or leſs a ſound: but ſome, wanting elaſticity, give back no repetition of the ſound; the noiſe is at once begotten and dies: while other bodies, however, there are, which being more elaſtic and capable of vibration, give back a ſound, and repeat the ſame ſeveral times ſucceſſively. Theſe laſt are ſaid to have a tone; the others are not allowed to have any.

This tone of the elaſtic ſtring, or bell, is notwithſtanding nothing more than a ſimilar ſound of what the former bodies produced, but with the difference of being many times repeated while their notes is but ſingle. So that, if we would give the former bodies a tone, it will be neceſſary to make them repeat their ſound, by repeating our blows ſwiftly upon them. This will effectually give them a tone; and even an unmuſical inſtrument has often had a fine effect by its tone in our concerts.

We now then come to a critical queſtion, what is it that produces the difference of tone in two elaſtic ſounding bells or ſtrings? Or what makes one deep and the other ſhrill? This queſtion has always been hitherto anſwered by ſaying, that the depth or height of the note proceeded from the ſlowneſs or ſwiftneſs of the times of the vibrations. The ſloweſt vibrations, it has been ſaid, are qualified for producing the deepeſt tones, while the ſwifteſt vibrations produce the higheſt tones. In this caſe, an effect has been given for a cauſe. It is in fact the force with which the ſounding ſtring ſtrikes the air when ſtruck upon, that makes the true diſtinction in the tones of ſounds. It is this force, with greater or leſs impreſſions, reſembling the greater or leſs force of the blows upon a non-elaſtic body, which produces correſpondent affections of ſound. The greateſt forces produce the deepeſt ſounds: the high notes are the effect of ſmall efforts. In the ſame manner a bell, wide at the mouth, gives a grave ſound; but if it be very maſſy withal, that will render it ſtill graver; but if maſſy, wide, and long or high, that will make the tone deepeſt of all.

Thus, then, will elaſtic bodies give the deepeſt ſonnd, in proportion to the force with which they ſtrike the air: but if we ſhould attempt to increaſe their force by giving them a ſtronger blow, this will be in vain; they will ſtill return the ſame tone; for ſuch is their formation, that they are ſonorous only becauſe they are elaſtic, and the force of this elaſticity is not increaſed by our ſtrength, as the greatneſs of a pendulum's vibration will not be increaſed by falling from a greater height.

Thus far of the length of chords. Now as to the frequency with which they vibrate the deepeſt tones, it has been found, from the nature of elaſtic ſtrings, that the longeſt ſtrings have the wideſt vibrations, and conſequently go backward and forward ſloweſt; while, on the contrary, the ſhorteſt ſtrings vibrate the quickeſt, or come and go in the ſhorteſt intervals. From hence thoſe who have treated of ſounds, have aſſerted, as was ſaid before, that the tone of the ſtring depended upon the length or the ſhortneſs of the vibrations. This, however, is not the caſe. One and the ſame ſtring, when ſtruck, muſt always, like the ſame pendulum, return preciſely ſimilar vibrations; but it is well known, that one and the ſame ſtring, when ſtruck npon, does not always return preciſely the ſame tone: ſo that in this caſe the vibrations follow one rule, and the tone another. The vibrations muſt be invariably the ſame in the ſame ſtring, which does not return the ſame tone invariably, as is well known to muſicians in general. In the violin, for inſtance, they can eaſily alter the tone of the ſtring an octave or eight notes higher, by a ſofter method of drawing the bow; and ſome are known thus to bring out the moſt charming airs imaginable. Theſe peculiar tones are by fidlers called *flute-notes*. The only reaſon, it has been alleged, that can be aſſigned for the ſame ſtring thus returning different tones, muſt certainly be the different force of its ſtrokes upon the air. In one caſe, it has double the tone of the other; becauſe upon the ſoft touches of the blow, only half its elaſticity is put into vibration.

From hence alſo we may account for the cauſe of thoſe charming melancholy gradations of ſound in the Eolian lyre. This inſtrument is eaſily made, being nothing more than a long narrow box of thin dale, about 30 inches long, 5 inches broad, and 1¼ inches deep, with a circle in the middle of the upper ſide or belly about 1½ inch diameter, pierced with ſmall holes. On this ſide are ſeven, ten, or fifteen or more ſtrings of very fine gut, ſtretched over bridges at each end, like the bridge of a fiddle, and ſcrewed up or relaxed with ſcrew-pins. The ſtrings are all tuned to one and the ſame note; and the inſtrument is placed in ſome current of air, where the wind can bruſh over its ſtrings with freedom. A window with the ſaſh juſt raiſed to give the air admiſſion, will anſwer this purpoſe exactly. Now when the entering air blows upon theſe ſtrings with different degrees of force, there will be excited different tones of ſound; ſometimes the blaſt brings out all the tones in full concert; ſometimes it ſinks them to the ſofteſt murmurs; it feels for every tone, and by its gradations of ſtrength ſolicits thoſe gradations of ſound, which art has taken different methods to produce.

We ſhall now conſider the loudneſs and lowneſs, or, as the muſicians ſpeak, the ſtrength and ſoftneſs of ſound. In vibrating elaſtic ſtrings, the loudneſs of the tone is in proportion to the deepneſs of the note; that is, in two ſtrings, all things in other circumſtances alike, the deepeſt tone will be loudeſt. In muſical inſtruments upon a different principle, as in the violin, it is otherwiſe; the tones are made in ſuch inſtruments, by a number of ſmall vibrations crowded into one ſtroke. The roſined bow, for inſtance, being drawn along a ſtring, its roughneſſes catch the ſtring at very ſmall intervals, and excite its vibrations. In this inſtrument, therefore, to excite loud tones, the bow muſt be drawn quick, and this will produce the greateſt number of vibrations. But it muſt be obſerved, that the more quick the bow paſſes over the ſtring, the leſs apt will the roughneſs of its ſurface be to touch the ſtring at every inſtant; to remedy this, therefore, the bow muſt be preſſed the harder, as it is drawn quicker, and thus its fulleſt ſound will be brought from the inſtrument. If the ſwiftneſs of the vibrations in an inſtrument thus rubbed upon, exceed the force of the deeper ſound in another, then the ſwift vibrations will be heard at a greater diſtance, and as much further off as the ſwiftneſs in them exceeds the force in the other.

But there is another property in the vibration of a muſical ſtring, which greatly tends to ſubſtantiate the foregoing theory. If we ſtrike the ſtring of an harpſichord, or any other elaſtic ſounding chord whatever, it returns a continuing ſound. This, till of late, was conſidered as one ſimple uniform tone; but all muſicians now confeſs, that inſtead of one tone it actually returns four tones, and that conſtantly. The notes are, beſides the fundamental tone, an octave above, a twelfth above, and a ſeventeenth. One of the baſs-notes of an harpſichord has been diſſected in this manner by Rameau, and the actual exiſtence of theſe tones proved beyond a poſſibility of being controverted. In fact, the experiment is eaſily tried; for if we ſmartly ſtrike one of the lower keys of an harpſichord, and then take the finger briſkly away, a tolerable ear will be able to diſtinguiſh, that, after the fundamental tone has ceaſed, three other ſhriller tones will be diſtinctly heard; firſt the octave above, then the twelfth, and laſtly the ſeventeenth: the octave above is in general almoſt mixed with the fundamental tone, ſo as not to be eaſily perceived, except by an ear long habituated to the minute diſcriminations of ſounds. So that we may obſerve, that the ſmalleſt tone is heard laſt, and the deepeſt and largeſt one firſt: the two others in order: in ſhort, in the whole theory of ſounds, nothing has given greater room for ſpeculation, conjecture, and diſappointment, than this amazing property in elaſtic ſtrings. The whole ſtring is univerſally acknowledged to be in vibration in all its parts, yet this ſingle vibration returns no leſs than four different ſounds. So that from hence we may juſtly infer, that every note whatſoever is only a ſucceſſion of tones; and that thoſe are moſt diſtinctly heard, whoſe differences are moſt eaſily perceivable.

In ſpeaking of elaſtic and non-elaſtic bodies in a muſical ſenſe, we are not to puſh the diſtinction ſo far as when we ſpeak of them philoſophically. A body is *muſically* elaſtic, all of whoſe parts are thrown into vibrations ſo as to emit a ſound when only part of their ſurface is ſtruck. Of this kind are bells, muſical ſtrings, and all bodies whatever that are conſiderably hollow. Muſical non-elaſtics are ſuch bodies as emit a ſound only from that particular place which is ſtruck: thus, a table, a plate of iron nailed on wood, a bell ſunk in the earth, are all of them non-elaſtics in a muſical ſenſe, though not philoſophically ſo. When a ſolid body, ſuch as a log of wood, is ſtruck with a ſwitch, only that part of it emits a ſound which comes in contact with the ſwitch; the note is acute and loud, but would be no leſs ſo though the adjacent parts of the log were removed. If, inſtead of the ſwitch, a heavier or larger inſtrument is made uſe of, a larger portion of its ſurface then returns a ſound, and the note is conſequently more grave ; but it would not be ſo if the large inſtrument ſtruck with a ſharp edge, or a ſurface only equal to that of the ſmall one.

In ſounds of this kind, where there is only a ſingle thwack, without any repetition, the immediate cauſe of the gravity or acuteneſs ſeems to be the quantity of air diſplaced by the ſounding body ; a large quantity of air diſplaced produces a grave ſound, and a ſmaller quantity a more acute one, the force wherewith the air is diſplaced ſignifying very little. Dr. Prieſtley has made ſome curious experiments concerning the *muſical tone* of electrical diſcharges. The paſſage being entertaining, and not very long, we ſhall here tranſcribe it.

" As the courſe of my experiments has required a great variety of electrical exploſions, I could not help obſerving a great variety in the muſical tone made by the reports. This excited my curioſity to attempt to reduce this variation to ſome meaſure. Accordingly, by the help of a couple of ſpinets, and two perſons who had good ears for muſic, I endeavoured to aſcertain the tone of ſome electrical diſcharges ; and obſerved, that every diſcharge made ſeveral ſtrings, particularly thoſe that were chords to one another, to vibrate: but one note was always predominant, and ſounded after the reſt. As every exploſion was repeated ſeveral times, and three of us ſeparately took the ſame note, there remained no doubt but that the tone we fixed upon was at leaſt very near the true one. The reſult was as follows :

" A jar containing half a ſquare foot of coated glaſs ſounded F ſharp, concert pitch. Another jar of a different form, but equal ſurface, ſounded the ſame.

" A jar of three ſquare feet ſounded C below F ſharp. A battery conſiſting of ſixty-four jars, each containing half a ſquare foot, ſounded F below the C.

" The ſame battery, in conjunction with another of thirty-one jars, ſounded C ſharp. So that a greater quantity of coated glaſs always gave a deeper note.

" Differences in the degree of a charge in the ſame jar made little or no difference in the tone of the exploſion : if any, a higher charge gave rather a deeper note."

Theſe experiments ſhew us how much the gravity or acuteneſs of ſounds depend on the quantity of air put in agitation by the ſounding body. We know that the noiſe of the electric exploſion ariſes from the return of the air into the vacuum produced by the electric flaſh. The larger the vacuum, the deeper was the note ; for the ſame reaſon, the diſcharge of a muſket produces a more acute note than that of a cannon ; and thunder is deeper than either.

The foregoing argument uſed by Dr. Prieſtley on the production of what are called *flute-notes* on the violin, we conceive to be built on a falſe foundation ; for the bow being lightly drawn on an open ſtring, produces no flute-notes, but only the harmonies of the note to which the ſtring is tuned. The flute-notes are produced by a particular motion of the bow, quick and near the bridge, and by fingering very gently. By this management, the ſame ſounds are produced, though at certain intervals only, as if the vibrations were transferred to the ſpace between the end of the finger-board and the finger, inſtead of that between the finger and the bridge. Why this ſmall part of the ſtring ſhould vibrate in ſuch a caſe, and not that which is under the immediate action of the bow, we muſt own ourſelves ignorant : nor dare we affirm that the vibrations really are transferred in this manner, only the ſame ſounds are produced as if they were.

Though theſe objections ſeem ſufficiently to over-turn the foregoing theory, with regard to acute ſounds being the effects of weak ſtrokes, and grave ones of ſtronger impulſes, we cannot admit that longer or ſhorter vibrations are the occaſion of gravity or acuteneſs in ſound. A muſical ſound, however lengthened, either by ſtring or bell, is only a repetition of a ſingle one, whoſe duration by itſelf is but for a moment, and is therefore termed inappretiable, like the ſmack of a whip, or the exploſion of an electrical battery. The continuation of the ſound is nothing more than a repetition of this inſtantaneous inappretiable noiſe after the manner of an echo, and it is only this that makes the ſound agreeable. For this reaſon, muſic is much more agreeable when played in a large hall where the ſound is reverberated, than in a ſmall room where there is no ſuch reverberation. For the ſame reaſon, the ſound of a ſtring is more agreeable when put on a hollow violin, than when faſtened to a plain board, &c. In the ſound of a bell, we cannot avoid obſerving this echo very diſtinctly. The ſound appears to be made up of diſtinct pulſes, or repetitions of the ſame note produced by the ſtroke of the hammer. It can by no means be allowed, that the note would be more acute though theſe pulſes were to ſucceed one another more rapidly ; the ſound would indeed become more ſimple, but would ſtill preſerve the ſame tone. In muſical ſtrings the reverberations are vaſtly more quick than in bells ; and therefore their ſound is more uniform or ſimple, and conſequently more agreeable than that of bells. In muſical glaſſes, the vibrations muſt be inconceivably quicker than in any bell, or ſtringed inſtrument : and hence they are of all others the moſt ſimple and the moſt agreeable, though neither the moſt acute nor the loudeſt. As far as we can judge, quickneſs of vibration contributes to the uniformity, or ſimplicity, but not to the acuteneſs, nor to the loudneſs, of a muſical note.

DEFINITION II.

Under this head we ſhall treat of the propagation of ſounds, and take notice of the obſervations made, among others, by the ingenious Dr. Young, of Trinity College, Dublin, who ſtates them as follow :

" 1. The parts of all ſounding bodies, he obſerves, vibrate according to the law of a cycloidal pendulum : for they may be conſidered as compoſed of an indefinite number of elaſtic fibres ; but theſe fibres vibrate according to that law. Vide Helſham, p. 270.

" 2. Sounding bodies propagate their motions on all ſides *in directum*, by ſucceſſive condenſations and rarefactions, and ſucceſſive goings forward and returnings backward of the particles. Vide Prop. 43. B. 2. Newton.

" 3. The pulſes are thoſe parts of the air which vibrate backwards and forwards ; and which, by going forward, ſtrike (pulſant) againſt obſtacles. The latitude of a pulſe is the rectilineal ſpace through which the motion of the air is propagated during one vibration of the ſounding body.

" 4. All pulſes move equally faſt. This is proved by experiment ; and it is found that they deſcribe 1070 Paris feet, or 1142 London feet in a ſecond, whether the ſound be loud or low, grave or acute.

" 5. To determine the latitude of a pulſe. Divide the ſpace which the pulſe deſcribes in a given time (4) by the number of vibrations performed in the ſame time by the ſounding body, Cor. 1. Prop. 24. Smith's Harmonics, the quotient is the latitude.

" M. Sauveur, by ſome experiments on organ-pipes, found that a body, which gives the graveſt harmonic ſound, vibrates 12 times and a half in a ſecond, and that the ſhrilleſt ſounding body vibrates 51.100 times in a ſecond. At a medium, let us take the body which gives what Sauveur calls his fixed ſound : it performs 100 vibrations in a ſecond, and in the ſame time the pulſes deſcribe 1070 Pariſian feet ; therefore the ſpace deſcribed by the pulſes whilſt the body vibrates once, that is the latitude or interval of the pulſe, will be 10.7 feet.

" 6. To find the proportion which the greateſt ſpace, through which the particles of the air vibrate, bears to the radius of a circle, whoſe perimeter is equal to the latitude of the pulſe.

" During the firſt half of the progreſs of the elaſtic fibre, or ſounding body, it is continually getting nearer to the next particle ; and during the latter half of its progreſs, that particle is getting farther from the fibre, and theſe portions of time are equal (Helſham): therefore we may conclude, that at the end of the progreſs of the fibre, the firſt particle of air will be nearly as far diſtant from the fibre as when it began to move ; and in the ſame manner we may infer, that all the particles vibrate through ſpaces nearly equal to that run over by the fibre.

" Now, M. Sauveur (Acad. Science, an. 1700, p. 141) has found by experiment, that the middle point of a chord which produces his fixed ſound, and whoſe diameter is 1-6th of a line, runs over in its ſmalleſt ſenſible vibrations 1-18th of a line, and in its greateſt vibrations 72 times that ſpace ; that is 72 × 1-18th of a line, or 4 lines, that is, 1-3d of an inch.

" The latitude of the pulſes of this fixed ſound is 10.7 feet (5) ; and ſince the circumference of a circle is to its radius as 710 is to 113, the greateſt ſpace deſcribed by the particles will be to the radius of a circle, whoſe periphery is equal to the latitude of the pulſe as 1-3d of an inch is to 1.7029 feet, or 20.4348 inches, that is, as 1 to 61.3044.

" If the length of the ſtring be increaſed or diminiſhed in any proportion, *cæteris paribus*, the greateſt ſpace deſcribed by its middle point will vary in the ſame proportion. For the inflecting force is to the tending force as the diſtance of the ſtring from the middle point of vibration to half the length of the ſtring (ſee Helſham and Martin) ; and therefore the inflecting and tending forces being given, the ſtring will vibrate through ſpaces proportional to its length : but the latitude of the pulſe is inverſely as the number of vibrations performed by the ſtring in a given time, (5) that is, directly as the time of one vibration, or directly as the length of the ſtring (Prop. 24, Cor. 7. Smith's Harmonics) ; therefore the greateſt ſpace through which the middle point of the ſtring vibrates, will vary in the direct ratio of the latitude of the pulſe, or of the radius of a circle whoſe circumference is equal to the latitude, that is, it will be to that radius as 1 to 61.3044.

" 7. If the particles of the aërial pulſes, during any part of their vibration, be ſucceſſively agitated, according to the law of a cycloidal pendulum, the comparative elaſtic forces ariſing from their mutual action, by which they will afterwards be agitated, will be ſuch as will cauſe the particles to continue that motion, according to the ſame law, to the end of their vibration.

" 8. If a particle of the medium be agitated, according to the law of a cycloidal pendulum, the comparative elaſtic force, acting on the adjacent particle, from the inſtant in which it begins to move, will be ſuch as will cauſe it to continue its motion, according to the ſame law.

" 9. To find the velocity of the pulſes, the denſity and elaſtic force of the medium being given.

" This is the 49th Prop. B. 2. Newton, in which he ſhews, that whilſt a pendulum, whoſe length is equal to the height of the homogeneous atmoſphere, vibrates once forwards and backwards, the pulſes will deſcribe a ſpace equal to the periphery of a circle deſcribed with that altitude as its radius.

" Cor. 1. He thence ſhews, that the velocity of the pulſes is equal to that which a heavy body would acquire in falling down half the latitude of that homogeneous atmoſphere; and therefore, that all pulſes move equally faſt, whatever be the magnitude or time of its being deſcribed; that is, whether the tone be loud or low, grave or acute. See *Hales de Sonis*, § 49.

" Cor. 2. And alſo, that the velocity of the pulſes is in a ratio compounded of the direct ſubduplicate ration of the elaſtic force of the medium, and the inverſe ſubduplicate of its denſity. Hence ſounds move ſomewhat faſter in ſummer than in winter. See *Hales de Sonis*, p. 141.

" 10. The ſtrength of a tone is as the moment of the particles of air. The moment of theſe particles, (the medium being given) is as their velocity; and the velocity of theſe particles is as the velocity of the ſtring which ſets them in motion. The velocities of two different ſtrings are equal when the ſpaces which they deſcribe in their vibrations are to each other as the times of theſe vibrations: therefore, two different tones are of equal ſtrength, when the ſpaces, through which the ſtrings producing them vibrate, are directly as the times of their vibration.

DEFINITION III.

Experience has taught us, that ſound travels at the rate of 1142 feet in a ſecond, or near 13 miles in a minute; nor do any obſtacles hinder its progreſs.

The method of calculating its progreſs is eaſily made known. When a gun is diſcharged at a diſtance, we ſee the fire long before we hear the ſound. If then we know the diſtance of the place, and know the time of the interval between our firſt ſeeing the fire and then hearing the report, this will ſhew us exactly the time the ſound has been travelling to us. For inſtance, if the gun is diſcharged a mile off, the moment the flaſh is ſeen, you take a watch and count the ſeconds till you hear the ſound; the number of ſeconds is the time the ſound has been travelling a mile. Again, by the above axiom, we are enabled to find the diſtance between objects that would be otherwiſe immeaſurable. For example, ſuppoſe you ſee the flaſh of a gun in the night at ſea, and tell ſeven ſeconds before you hear the report, it follows therefore, that the diſtance is ſeven times 1142 feet, that is, 24 yards more than a mile and a half. In like manner, if you obſerve the number of ſeconds between the lightning and the report of the thunder, you know the diſtance of the cloud from whence it proceeds.

Derham has proved by experience, that all ſounds whatever travel at the ſame rate. The ſound of a gun, and the ſtriking of a hammer, are equally ſwift in their motions; the ſofteſt whiſper flies as ſwiftly, as far as it goes, as the loudeſt thunder.

To theſe axioms we may add the following:

Smooth and clear ſounds proceed from bodies that are homogeneous, and of an uniform figure; and harſh or obtuſe ſounds, from ſuch as are of a mixed matter and irregular figure.

The velocity of ſound is to that of a briſk wind as fifty to one.

The ſtrength of ſounds is greateſt in cold and denſe air, and leaſt in that which is warm and rarified.

Every point againſt which the pulſes of ſound ſtrike, becomes a centre from which a new ſeries of pulſes are propagated in every direction.

Sound deſcribes equal ſpaces in equal times.

Sound, like light, after it has been reflected from ſeveral places, may be collected in one point, as into a focus; and it will be there more audible than in any other part, even than at the place from whence it proceeded. On this principle it is that a whiſpering gallery is conſtructed.

The form of this gallery muſt be that of a concave hemiſphere, and if a low ſound or whiſper be uttered, the vibrations will expand themſelves every way, till being brought to a point, the ſound will be diſtinctly heard.

The augmentation of ſound by means of ſpeaking-trumpets, is very conſiderable. When a perſon ſpeaks through one of theſe inſtruments, the whole force of his voice is ſpent upon the air contained in the tube, which will be agitated through the whole length of the tube; and, by various reflections from the ſide of the tube to the axis, the air along the middle part of the tube will be greatly condenſed, and its *momentum* proportionably increaſed, ſo that when it comes to agitate the air at the orifice of the tube, its force will be as much greater than what it would have been without the tube, as the ſurface of a ſphere, whoſe radius is equal to the length of the tube, is greater than the ſurface of the ſegment of ſuch a ſphere whoſe baſe is the orifice of the tube. For a perſon ſpeaking without the tube, will have the force of his voice ſpent in exciting concentric ſuperficies of air all around the mouth of the trumpet; and when thoſe ſuperficeis or pulſes of air are diffuſed, it is plain the force of the voice will there be diffuſed through the whole ſuperficies of a ſphere; but in the trumpet it will be ſo confined, that at its exit it will be diffuſed through ſo much of that ſpherical ſurface of air as correſponds to the orifice of the tube. But ſince the force is given, its intenſity will be always inverſely as the number of particles it has to move; and therefore in the tube it will be to that without, as the ſuperficies of ſuch a ſphere to the æra of the large end of the tube nearly.

The ingenious Kircher has ſuggeſted principles in his Phonurgia, which are deſerving our attention. He tells us, that " the augmentation of the ſound depends on its reflection from the tremulous ſides of the tube; which reflections, conſpiring in propagating the pulſes in the ſame direction, muſt increaſe its intenſity."

Sir Iſaac Newton ſeems alſo to have conſidered this as the principal cauſe, in the Scholium of Prop. 50. B. 2. Princip. when he ſays " we hence ſee why ſounds are ſo much increaſed in ſtenterophonic tubes, for every reciprocal motion is, in each return, increaſed by the generating cauſe.

Farther, when we ſpeak in the open air, the effect on the tympanum of a diſtant auditor is produced merely by a ſingle pulſe. But when we uſe a tube, all the pulſes propagated from the mouth, except thoſe in the direction of the axis, ſtrike againſt the ſides of the tube, and every point of impulſe becoming a new centre, from whence the pulſes are propagated in all directions, a pulſe will arrive at the ear from each of thoſe points; thus, by the uſe of a tube, a greater number of pulſes are propagated to the ear, and conſequently the ſound increaſed. The confinement too of the voice may have ſome effect, though not ſuch as is aſcribed to it by ſome; for the condenſed pulſes produced by the naked voice, freely expand every way; but in tubes, the lateral expanſion being diminiſhed, the direct expanſion will be increaſed, and conſequently the velocity of the particles and the intenſity of the ſound. The ſubſtance alſo of the tube has its effect; for it is found by experiment, that the more elaſtic the ſubſtance of the tube, and conſequently the more ſuſceptible it is of theſe tremulous motions, the ſtronger is the ſound.

If the tube be laid on any non-elaſtic ſubſtance, it deadens the ſound, becauſe it prevents the vibratory motion of the parts. The ſound is increaſed in ſpeaking-trumpets, if the tube be ſuſpended in the air; becauſe the agitations are then carried on without interruption. Theſe tubes ſhould increaſe in diameter from the mouth-piece, becauſe the parts, vibrating in directions perpendicular to the ſurface, will conſpire in impelling forward the particles of air, and conſequently, by increaſing their velocity, will increaſe the intenſity of the ſound: and the ſurface alſo increaſing, the number of points of impulſe and of new propagations will increaſe proportionally. The ſeveral cauſes, therefore, of the increaſe of ſound in theſe tubes, Mr. Young concludes to be, 1. The diminution of the lateral, and conſequently the increaſe of the direct, expanſion and velocity of the included air. 2. The increaſe of the number of pulſes, by increaſing the points of new propagation. 3. The reflections of the pulſes from the tremulous ſides of the tube, which impel the particles of air forward, and thus increaſe their velocity.

An echo is a reflection of ſound ſtriking againſt ſome object, as an image is reflected in a glaſs: but it has been diſputed what are the proper qualities in a body for thus reflecting ſounds. It is in general known, that caverns, grottos, mountains, and ruined buildings, return this image of ſound. We have heard of a very extraordinary echo, at a ruined fortreſs near Louvain, in Flanders. If a perſon ſung, he only heard his own voice, without any repetition: on the contrary, thoſe who ſtood at ſome diſtance, heard the echo but not the voice; but then they heard it with ſurpriſing variations, ſometimes louder, ſometimes ſofter, now more near, then more diſtant. There is an account in the memoirs of the French academy, of a ſimilar echo near Rouen.

As there may be ſeveral ſphæroids of different magnitudes, ſo there may be ſeveral different echoes of the ſame original ſound. And as there may happen to be a greater number of reflecting points in the ſurface of an exterior ſphæroid than in that of an interior, a ſecond or a third echo may be much more powerful than the firſt, provided that the ſuperior number of reflecting points, that is, the ſuperior number of reeflected pulſes propagated to the ear, be more than ſufficient to compenſate for the decay of ſound which ariſes from its being propagated through a greater ſpace. This is finely illuſtrated in the celebrated echoes at the lake of Killarney in the county of Kerry, in Ireland, where the firſt return of the ſound is much inferior in ſtrength to thoſe which immediately ſucceed it.

From what has been laid down it appears, that for the moſt powerful echo, the ſounding body ſhould be in one focus of the ellipſe, which is the ſection of the echoing ſphæroid, and the hearer in the other. However, an echo may be heard in other ſituations, though not ſo favourably; as ſuch a number of reflected pulſes may arrive at the ſame time at the ear as may be ſufficient to excite a diſtinct perception.

In churches we never hear a diſtinct echo of the voice, but a confuſed ſound when the ſpeaker utters his words too rapidly; becauſe the greateſt difference of diſtance between the direct and reflected courſes of ſuch a number of pulſes as would produce a diſtinct ſound, is never in any church equal to 127 feet, the limit of echoes.

But though the firſt reflected pulſes may produce no echo, both on account of their being too few in number, and too rapid in their return to the ear; yet it is evident, that the reflecting ſurface may be ſo formed, as that the pulſes which come to the ear after two reflections or more may, after having deſcribed 127 feet or more, arrive at the ear in ſufficient numbers, and alſo ſo nearly at the ſame inſtant, as to produce an echo, though the diſtance of the reflecting ſurface from the ear be leſs than the limit of echoes. This is confirmed by a ſingular echo in a grotto on the banks of the little brook called the Dinan, about two miles from Caſtlecomber, in the county of Kilkenny. As you enter the cave, and continue ſpeaking loud, no return of the voice is perceived; but on your arriving at a certain point which is not above 14 or 15 feet from the reflecting ſurface, a very diſtinct echo is heard. Now this echo cannot ariſe from the firſt courſe of pulſes that are reflected to the ear, becauſe the breadth of the cave is ſo ſmall, that they would return too quickly to produce a diſtinct ſenſation from that of the original ſound: it therefore is produced by thoſe pulſes, which, after having been reflected ſeveral times from one ſide of the grotto to the other, and having run over a greater ſpace than 127 feet, arrive at the ear in conſiderable numbers, and not more diſtant from each other in point of time, than the ninth part of a ſecond.

We ſhall diſmiſs this article with a few entertaining experiments, founded on ſome of the preceding principles.

I. Place a concave mirror of about two feet diameter, in a perpendicular direction. The focus of this mirror may be at 15 or 18 inches diſtance from its ſurface. At the diſtance of about five or ſix feet let there be a partition, in which there is an opening, equal to the ſize of the mirror; againſt this opening muſt be placed a picture, painted in water-colours, on a thin cloth, that the ſound may eaſily paſs through it.

Behind the partition, at the diſtance of two or three feet, place another mirror of the ſame ſize as the former, and let it be immediately oppoſite to it; at the point of which let there be placed the figure of a man ſeated on a pedeſtal, and let his ear be placed exactly in the focus of the firſt mirror: his lower jaw muſt be made to open by a wire, and ſhut by a ſpring; and there may be another wire to move the eyes: theſe wires muſt paſs through the figure, go under the floor, and come up behind the partition.

Let a perſon, properly inſtructed, be placed behind the partition near the mirror. You then propoſe to any one to ſpeak ſoftly to the ſtatue, by putting his mouth to the ear of it, aſſuring him that it will anſwer inſtantly. You then give the ſignal to the perſon behind the partition, who, by placing his ear to the focus of the mirror, will hear diſtinctly what the other ſaid; and, moving the jaw and eyes of the ſtatue by the wires, will return an anſwer directly, which will in like manner be diſtinctly heard by the firſt ſpeaker.

This experiment appears to be taken from the Century of Inventions of the Marquis of Worceſter; whoſe deſigns, at the time they were publiſhed, were treated with ridicule and neglect as being impracticable, but are now known to be generally if not univerſally practicable. The words of the Marquis are theſe: "How to make a brazen or ſtone head in the midſt of a great field or garden, ſo artificial and natural, that though a man ſpeak ever ſo ſoftly, and even whiſper into the ear thereof, it will preſently open its mouth, and reſolve the queſtion in French, Latin, Welſh, Iriſh, or Engliſh, in good terms, uttering it out of its mouth, and then ſhut it until the next queſtion be aſked.

The two following, of a ſimilar nature, appear to have been inventions of Kircher, by means of which (as he informs us) he uſed to utter feigned and ludicrous conſultations, with a view to ſhew the fallacy and impoſture of ancient oracles.

II. Let there be two heads of plaſter of Paris, placed on pedeſtals, on the oppoſite ſides of a room. There muſt be a tin tube of an inch diameter, that muſt paſs from the ear of one head through the pedeſtal, under the floor, and go up to the mouth of the other. Obſerve, that the end of the tube which is next the ear of the one head, ſhould be conſiderably larger than that end which comes to the mouth of the other. Let the whole be ſo diſpoſed that there may not be the leaſt ſuſpicion of a communication.

Now, when a perſon ſpeaks, quite low, into the ear of one buſt, the ſound is reverberated through the length of the tube, and will be diſtinctly heard by any one who ſhall place his ear to the mouth of the other. It is not neceſſary that the tube ſhould come to the lips of the buſt. If there be two cubes, one going to the ear, and the other to the mouth, of each head, two perſons may converſe together, by applying their mouth and ear, reciprocally to the mouth and ear of the buſts; and at the ſame time other perſons that ſtand in the middle of the chamber, between the heads, will not hear any part of their converſation.

III. Place a buſt on a pedeſtal in the corner of a room, and let there be two tubes, as in the foregoing experiment, one of which muſt go from the mouth and the other from the ear of the buſt, through the pedeſtal, and the floor, to an under apartment. There may be likewiſe wires that go from the under jaw and the eyes of the buſt, by which they may be eaſily moved.

A perſon being placed in the under room, and at a ſignal given applying his ear to one of the tubes, will hear any queſtion that is aſked, and immediately reply; moving at the ſame time, by means of the wires, the mouth and the eyes of the buſt, as if the reply came from it.

IV. In a large caſe, ſuch as is uſed for dials and ſpring-clocks, the front of which, or at leaſt the lower part of it, muſt be of glaſs, covered on the inſide with gauze, let there be placed a barrel-organ, which, when wound up, is prevented from playing, by a catch that takes a toothed wheel at the end of the barrel. To one end of this catch there muſt be joined a wire, at the end of which there is a flat circle of cork, of the ſame dimenſion with the inſide of a glaſs tube, in which it is to riſe and fall. This tube muſt communicate with a reſervoir that goes a croſs the front part of the bottom of the caſe, which is to be filled with ſpirits, ſuch as is uſed in thermometers, but not coloured, that it may be the better concealed by the gauze.

This caſe being placed in the ſun, the ſpirits will be rarefied by the heat; and riſing in the tube, will lift up the catch or trigger, and ſet the organ in play; which it will continue to do as long as it is kept in the ſun; for the ſpirits cannot run out of the tube, that part of the catch to which the circle is fixed being prevented from riſing beyond a certain point by a check placed over it.

When the machine is placed againſt the ſide of a room on which the ſun ſhines ſtrong, it may conſtantly remain in the ſame place, if you incloſe it in a ſecond caſe, made of thick wood, and placed at a little diſtance from the other. When you want it to perform, it will be only neceſſary to throw open the door of the outer caſe, and expoſe it to the ſun.

But if the machine be moveable, it will perform in all ſeaſons by being placed before the fire; and in the winter it will more readily ſtop when removed into the cold.

A machine of this ſort is ſaid to have been invented by Cornelius Dreble, in the laſt century. What the conſtruction of that was, we know not; it might very likely be more complex, but could ſcarce anſwer the intention more readily.

V. Under the keys of a common harpſichord let there be fixed a barrel, ſomething like that in a chamber organ, with ſtops or pins correſponding to the tunes you would have it play. Theſe ſtops muſt be moveable, ſo that the tunes may be varied at pleaſure. From each of the keys let there go a wire perpendicular down: the ends of theſe wires muſt be turned up for about one-fourth of an inch. Behind theſe wires let there be an iron bar, to prevent them from going too far back. Now, as the barrel turns round, its pins take the ends of the wires, which pull down the keys, and play the harpſichord. The barrel and wires are to be all incloſed in a caſe.

In the chimney of the ſame room where the harpſichord ſtands, or at leaſt in one adjacent, there muſt be a ſmoak-jack, from whence comes down a wire, or cord, that, paſſing behind the wainſcot adjoining the chimney, goes under the floor, and up one of the legs of the harpſichord, into the caſe, and round a ſmall wheel fixed on the axis of that firſt mentioned. There ſhould be pullies at different diſtances, behind the wainſcot and under the floor, to facilitate the motion of the chord.

This machinery may be applied to any other keyed inſtrument as well as to chimes, and to many other purpoſes where a regular continued motion is required.

An inſtrument of this ſort may be conſidered as a perpetual motion, according to the vulgar acceptation of the term; for it will never ceaſe going till the fire be extinguiſhed, or ſome parts of the machinery be worn out.

ACQUIETANDES Plegiis, a writ of juſtices, lying for a ſurety againſt the creditor that refuſes to acquit him after the debt is paid.

ACQUISITION, in general, denotes the obtaining or procuring ſomething. Among lawyers, it is uſed for the right or title to an eſtate got by purchaſe or donation.

ACQUITTAL, a diſcharge, deliverance, or ſetting of a perſon free from the guilt or ſuſpicion of an offence.

ACQUITTANCE, a releaſe or diſcharge in writing for a ſum of money, witneſſing that the party has paid the ſaid ſum. No man is obliged to pay a ſum of money if the demandant refuſes to give an acquittance, which is a full diſcharge, and bars all actions, &c. An acquittance given by a ſervant for a ſum of money received for the uſe of his maſter, ſhall be a good diſcharge for that ſum, provided the ſervant uſed to receive his maſter's rents, debts, &c.

ACRASIA, among phyſicians, implies the predominancy of one quality above another, either with regard to artificial mixtures, or the humours of the human body.

ACRATISMA, in antiquity, a breakfaſt among the old Greeks, conſiſting of a morſel of bread ſoaked in pure unmixed wine.

ACRE, the univerſal meaſure of land in Britain. The word formed from the Saxon *acher*, or the German *aker*, a field. An acre in England contains four ſquare roods, a rood 40 perches or poles of $16\frac{1}{2}$ feet each by ſtatute. Yet this meaſure does not prevail in all parts of England, as the length of the pole varies in different counties, and is called cuſtomary meaſure, the difference running from the $16\frac{1}{2}$ feet to 28. The acre is alſo divided into 10 ſquare chains, of 22 yards each, that is, 4840 ſquare yards. An acre in Scotland contains four ſquare roods; one ſquare rood is 40 ſquare falls; one ſquare fall, 36 ſquare ells; one ſquare ell, nine ſquare feet and 73 ſquare inches; one ſquare foot, 144 ſquare inches. The Scots acre is alſo divided into 10 ſquare chains; the meaſuring chain ſhould be 24 ells in length, divided into 100 links, each link $8\frac{928}{1000}$ inches; and ſo one ſquare chain will contain 10,000 ſquare links.

Acre *Fight*, an old ſort of duel fought by Engliſh and Scottiſh combatants, between the frontiers of their kingdoms, with ſword and lance: it was alſo called camp-fight, and the combatants champions, from the open field being the ſtage of trial.

Acre *Tax*, a tax laid on land at ſo much per acre. In ſome places this is alſo called acre-ſhot. Impoſitions on lands in the great level are to be raiſed by a proportionable acre-tax, 20 Car. II. cap 8. An acre-tax of 2s. 6d. per acre, for draining Hadenham-level, 13 Geo. I. cap. 18.

ACREME, in ancient law-books, 10 acres ſtatute meaſure.

ACRIBEIA, a term purely Greek, literally denoting an exquiſite or delicate accuracy; ſometimes uſed in our language, for want of a word of equal ſignification.

ACRID, a name for any thing that is of a ſharp or pungent taſte.

ACRIMONY, that quality which renders things acrid to the taſte. Alſo implies aſperity, or ſharpneſs of temper.

ACRIS, the extremities of fractured bones.

ACROAMATIC, in general, denotes a thing ſublime, profound, or abſtruſe. It is ſometimes uſed for any thing kept ſecret, or remote from popular uſe.

ACROAMATICI, a denomination given the diſciples or followers of Ariſtotle, &c. who were admitted into the ſecrets of the inner or acroamatic philoſophy.

ACROATIC. Ariſtotle's lectures to his diſciples were of two kinds, exoteric and acroatic. The acroatic were thoſe to which only his own diſciples and intimate friends were admitted; whereas the exoteric were public, and open to all. But there are other differences. The acroatic were ſet apart for the higher and more abſtruſe ſubjects; the exoteric were employed in rhetorical and civil ſpeculations.

ACROBATICA, or Acrobaticum, from ακρος, high, and βαδεω, or βαινω, I go; an ancient engine, whereby people were raiſed aloft, that they might ſee more conveniently about them. The *acrobatica* among the Greeks amounted to the ſame with what they call *ſcanſorium* among the Latins.

ACROCHERISMUS, among the Greeks, a ſort of gymnaſtic exerciſe, in which the two combatants contended with their hands and fingers only, without cloſing or engaging the other parts of the body.

ACROCHORDON, a painful ſort of wart, very prominent and pendulous, having a large head, with a ſmall pedicle or baſe.

ACROCOLIA ſignifies the extremities of animals which are uſed in food, as the feet of calves, ſwine, ſheep, oxen, or lambs, and from which jellies are made. They are recommended by Hippocrates as a proper food where there is a tendency to a dropſy. They are in general recommended as ſtrengtheners to people of weak conſtitutions.

ACROCORION, in botany, a name uſed by ſome authors for the ſeveral ſpecies of the ſpring crocuſes.

ACROE, in botany, the Guinea trefoil. See Phil. Tranſ. No. 232.

ACROMATIC, in optics, a term applied to a particular ſpecies of teleſcope, the moſt perfect of the refracting kind.

ACROMION, in anatomy, the upper part of the ſcapula, or ſhoulder-blade. See System of Anatomy.

ACROMONOGRAMMATICUM, in poetry, a kind of poem, wherein every ſubſequent verſe begins with the letter wherewith the immediately preceding one terminated.

ACROMPHALION, the tip of the navel.

ACRONICAL, Achronycal, or Achronical, in aſtronomy, is a term applied to the riſing of a ſtar, when the ſun is ſet in the evening; but has been promiſcuouſly uſed to expreſs a ſtar's riſing at ſunſet, or ſetting at ſun-riſe.

ACRONYCTÆ, ſtars riſing before twilight, or about ſun-ſet.

ACROSPIRE, a vulgar term for what botaniſts call the plume.

ACROSPIRED, in malt-making, is the grain's ſhooting both at the root and blade end.

ACROSTIC, in poetry, a kind of poetical compoſition, diſpoſed in ſuch a manner, that the initial letters of the verſes form the name of ſome perſon, kingdom, place, motto, &c.

ACROSTICUM, Rustyback, Wall-rue, or Fork-fern, in the Linnæan ſyſtem of botany, a genus of the cryptogamia filices.

ACROSTOLIUM, in ancient naval architecture, the extreme part of the ornament uſed on the prows of their ſhips, which was ſometimes in the ſhape of a buckler, helmet, animal, &c. but more frequently circular, or ſpiral. It was uſual to tear them from the prows of vanquiſhed veſſels, and fix them to the conquerors, as a ſignal of victory.

ACROTELEUTIC, among eccleſiaſtic writers, an appellation given to any thing added to the end of a pſalm; as the Gloria Patri, or Doxology.

ACROTERIA, in architecture, ſmall pedeſtals, uſually without baſes, anciently placed at the middle or two extremes of pediments or frontiſpieces, ſerving to ſupport the ſtatues, &c. It alſo ſignifies the figures placed as ornaments on the tops of churches, and the ſharp pinnacles that ſtand in ranges about flat buildings, with rails and balluſters.

Among ancient phyſicians, it ſignified the larger extremities of the body, as the head, hands, and feet. It has alſo been uſed for the tips of the fingers, and ſometimes for the eminences or proceſſes of bones.

ACROTERIASM, in ſurgery, the amputation of any extremity when putrified.

ACROTHYMIA, in ſurgery, the name of a large tumor in the fleſh, riſing in the ſhape of a wart, though ſometimes depreſſed and flat, called Thymus.

ACROTHYMION, from ακρος, *extreme*, and θυμος, *thyme*. A ſort of wart deſcribed by Celſus as hard, rough, with a narrow baſis and broad top; the top is of the colour of thyme; it eaſily ſplits and bleeds.

ACT, in general, denotes the exertion of power; and differs from power, as the effect from the cauſe.

Act, in logic, is particularly underſtood of an operation of the human mind. There are voluntary and ſpontaneous acts; the former are produced by the operation of the ſoul, the latter without its privity or participation.

Act, in the univerſities, ſignifies a theſis maintained in public by a candidate for a degree, or to ſhow the capacity and proficiency of a ſtudent. The candidates for a degree of bachelor and maſter of arts are to hold philoſophical acts; and thoſe for bachelor of divinity, theological acts, &c. At Oxford, the time when maſters or doctors complete their degrees is alſo called *the act*, which is held with great ſolemnity. At Cambridge, they call it the *commencement*.

Act *of Faith*, *Auto da Fe*, in the Romiſh church, is a ſolemn day held by the inquiſition, for the puniſhment of heretics, and the abſolution of the innocent accuſed. They uſually contrive the Auto to fall on ſome great feſtival, that the execution may paſs with the more awe and regard; at leaſt it is always on a Sunday.

The *Auto da Fe* may be called the laſt act of the inquiſitorial tragedy; it is a kind of gaol-delivery, appointed as oft as a competent number of priſoners in the inquiſition are convicted of hereſy, either by their own voluntary or extorted confeſſion, or on the evidence of certain witneſſes. The proceſs is thus: in the morning they are brought into a great hall, where they have certain habits put on, which they are to wear in the proceſſion. The proceſſion is led up by Dominican friars; after which come the penitents, ſome with ſan-benitoes, and ſome without, according to the nature of their crimes; being all in black coats without ſleeves, and bare-footed, with a wax candle in their hands. Theſe are followed by the penitents who have narrowly eſcaped being burnt, who over their black coats have flames painted with their points turned downwards, *Fuego revolto*. Next come the negative, and relapſed, who are to be burnt, having flames on their habits pointing upwards. After theſe come ſuch as profeſs doctrines contrary to the faith of Rome, who, beſides flames pointing upwards, have their picture painted on their breaſts, with dogs, ſerpents, and devils, all open-mouthed, about it. Each priſoner is attended with a familiar of the inquiſition; and thoſe to be burnt have alſo a Jeſuit on each hand, who are continually preaching to them to abjure. After the priſoners comes a troop of familiars on horſeback; and after them the inquiſitors, and other officers of the court, on mules; laſt of all, the inquiſitor-general on a white horſe, led by two men with black hats and green hat-bands. A ſcaffold is erected in the *Terriera de Paio*, big enough for two or three thouſand people; at one end of which are the priſoners, at the other the inquiſitors. After a ſermon made up of encomiums of the inquiſition, and invectives againſt heretics, a prieſt aſcends a deſk near the middle of the ſcaffold, and having taken the abjuration of the penitents, recites the final ſentence of thoſe who are to be put to death; and delivers them to the ſecular arm, earneſtly beſeeching at the ſame time the ſecular power not to touch their blood, or put their lives in danger. The priſoners being thus in the hands of the civil magiſtrate are preſently loaded with chains, and carried firſt to the ſecular goal, and from thence in an hour or two brought before the civil judge; who, after aſking in what religion they intend to die, pronounces ſentence, on ſuch as declare they die in the communion of the church of Rome, that they ſhall be firſt ſtrangled, and then burnt to aſhes; on ſuch as die in any other faith, that they be burnt alive. Both are immediately carried to the Ribera, the place of execution; where there are as many ſtakes ſet up as there are priſoners to be burnt, with a quantity of dry furz about them. The ſtakes of the profeſſed, that is, ſuch as perſiſt in their hereſy, are about four yards high, having a ſmall board towards the top for the priſoner to be ſeated on. The negative and relapſed being firſt ſtrangled and burnt, the profeſſed mount their ſtakes by a ladder; and the Jeſuits, after ſeveral repeated exhortations to be reconciled to the church, part with them, telling them they leave them to the devil, who is ſtanding at their elbow to receive their ſouls, and carry them with him into the flames of hell. On this a great ſhout is raiſed; and the cry is, let the dogs beards be made; which is done by thruſting flaming furzes faſtened to long poles againſt their faces, till their faces are burnt to a coal, which is accompanied with the loudeſt acclamations of joy. At laſt, fire is ſet to the furz at the bottom of the ſtake, over which the profeſſed are chained ſo high, that the top of the flame ſeldom reaches higher than the ſeat they ſit on; ſo that they rather ſeem roaſted than burnt. There cannot be a more lamentable ſpectacle; the ſufferers continually cry out, while they are able, *Miſericordia per amor de Dios*, "Pity for the love of God!" yet it is beheld by all ſexes, and ages, with tranſports of joy and ſatisfaction.

Act, in dramatic poetry, ſignifies a certain diviſion, or part, of a play, deſigned to give ſome reſpite, both to the actors and ſpectators. The Romans were the firſt who divided their theatrical pieces into acts; for no ſuch diviſions appear in the works of the firſt dramatic poets. Their pieces indeed conſiſted of ſeveral parts or diviſions, which they called *protaſis*, *epitaſis*, *cataſtaſis*, and *cataſtrophe*; but theſe diviſions were not marked by any real interruptions on the theatre. Nor does Ariſtotle mention any thing of acts in his Art of Poetry. But, in the time of Horace, all regular and finiſhed pieces were divided into five acts.

The firſt act, according to ſome critics, beſides introducing upon the ſtage the principal characters of the play, ought to propoſe the argument or ſubject of the piece; the ſecond, to exhibit this to the audience, by carrying the fable into execution; the third, to raiſe obſtacles and difficulties: the fourth, to remove theſe, or raiſe new ones in the attempt; and the fifth, to conclude the piece, by introducing ſome accident that may unravel the whole affair. This diviſion, however, is not eſſentially neceſſary; but may be varied according to the humour of the author, or the nature of the ſubject.

Act *of Grace*, a general releaſe of debtors, on the demiſe of a ſovereign, in Great Britain.

Act, among lawyers, is an inſtrument in writing for declaring or juſtifying the truth of any thing.

Acts, alſo denote the deliberations and reſolutions of an aſſembly, ſenate, or convention; as acts of parliament, &c.

Acta *Conſiſtorii*, the edicts or declarations of the council of ſtate of the emperors. Theſe edicts were generally expreſſed in ſuch terms as theſe: "The auguſt emperors, Diocleſian and Maximian, in council declared, that the children of Decurions ſhould not be expoſed to wild beaſts in the amphitheatre."

The ſenate and ſoldiers often ſwore, either through abject flattery or by compulſion, upon the edicts of the emperor, as we do upon the bible. And the name of Apidus Merula was eraſed by Nero out of the regiſter of ſenators, becauſe he refuſed to ſwear upon the edicts of the emperor Auguſtus.

Acta *Diurna*, was a ſort of Roman gazette, containing an authorized narrative of the tranſactions worthy of notice which happened at Rome.

Acta *Populi*, among the Romans, were journals or regiſters of the daily occurrences; as aſſemblies, trials, executions, buildings, births, marriages, deaths, &c. of illuſtrious perſons, and the like.

Acta *Senatus*, among the Romans, were minutes of what paſſed and was debated in the ſenate-houſe.

Public Acts. The knowledge of public acts forms part of a peculiar ſcience, called the diplomatic, of great importance to an hiſtorian, ſtateſman, chronologer, and even critic. The preſervation of them was the firſt occaſion of erecting libraries.

Acts *of the Apoſtles*, one of the ſacred books of the New Teſtament, containing the hiſtory of the infant-church, during the ſpace of 29 or 30 years from the aſcenſion of our Lord to the year of Chriſt 63. It was written by St. Luke; and addreſſed to Theophilus, the perſon to whom the evangeliſt had before dedicated his goſpel. We here find the accompliſhment of ſeveral of the promiſes made by our Saviour; his aſcenſion; the deſcent of the Holy Ghoſt; the firſt preaching of the apoſtles, and the miracles whereby their doctrines were confirmed; an admirable picture of the manners of the primitive Chriſtians; and, in ſhort, every thing that paſſed in the church till the diſperſion of the apoſtles, who ſeparated themſelves in order to propagate the goſpel throughout the world. From the period of that ſeparation, St. Luke quits the hiſtory of the other apoſtles, who were then at too great a diſtance from him, and confines himſelf more particularly to that of St. Paul, who had choſen him for the companion of his labours. He follows that apoſtle in all his miſſions, and even to Rome itſelf; for it appears that the Acts were publiſhed in the ſecond year of St. Paul's reſidence in that city, or the 36th year of the Chriſtian æra, and in the 9th or 10th year of Nero's reign. The ſtyle of this work, which was originally compoſed in Greek, is much purer than that of the other canonical writers; and it is obſervable, that St. Luke, who was much better acquainted with the Greek than with the Hebrew language, always, in his quotations from the Old Teſtament, makes uſe of the Septuagint verſion. The council of Laodicea places the Acts of the Apoſtles among the canonical books, and all the churches have acknowledged it as ſuch without any controverſy.

There were ſeveral ſpurious Acts of the Apoſtles; particularly, I. Acts, ſuppoſed to be written by Abdias, the pretended biſhop of Babylon, who gave out that he was ordained biſhop by the apoſtles themſelves when they were upon their journey into Perſia. II. The Actions of St. Peter: this book came originally from the ſchool of the Ebionites. III. The Acts of St. Paul, which is entirely loſt. Euſebius, who had ſeen it, pronounces it of no authority. IV. The Acts of St. John the Evangeliſt; a book made uſe of by the Encratites, Manichæans, and Priſcillianiſts. V. The Acts of St. Andrew; received by the Manichæans, Encratites, and Apotactics. VI. The Acts of St. Thomas the Apoſtle; received particularly by the Manichæans. VII. The Acts of St. Philip. This book the Gnoſtics made uſe of. VIII. The Acts of St. Matthias. Some have imagined that the Jews for a long time had concealed the original acts of the life and death of St. Matthias written in Hebrew; and that a monk of the abbey of St. Matthias at Treves, having got them out of their hands, procured them to be tranſlated into Latin, and publiſhed them; but the critics will not allow them to be authentic.

Acts of Pilate; a relation ſent by Pilate to the emperor Tiberius, concerning Jeſus Chriſt, his death, reſurrection, aſcenſion, and the crimes of which he was convicted before him. It was a cuſtom among the Romans, that the proconſuls and governors of provinces ſhould draw up acts, or memoirs, of what happened in the courſe of their government, and ſend them to the emperor and ſenate. The genuine Acts of Pilate were ſent by him to Tiberius, who reported them to the ſenate; but they were rejected by that aſſembly, becauſe not immediately addreſſed to them: as is teſtified by Tertullian, in his Apol. cap. 5. and 20, 21. The heretics forged Acts in imitation of them: in the reign of the emperor Maximin, the Gentiles, to throw an odium on the Chriſtian name, ſpread about ſpurious Acts of Pilate; which the emperor, by a ſolemn edict, ordered to be ſent into all the provinces of the empire, and enjoined the ſchool-maſters to teach and explain them to their ſcholars, and make them learn them by heart. Theſe acts, both the genuine and the ſpurious, are loſt. There is indeed extant, in Pſeudo-Hegeſippus, a letter from Pilate to the emperor Claudius, concerning Jeſus Chriſt; but it diſcovers itſelf at firſt ſight not to be authentic.

Act *of Parliament* is a poſitive law, conſiſting of two parts, the words of the act, and its true ſenſe and meaning; which being joined, make the law. The words of acts of parliament ſhould be taken in a lawful ſenſe. Caſes of the ſame nature are within the intention, though without the letter, of the act; and ſome acts extend by equity to things not mentioned therein.

ACTÆ, were meadows of remarkable verdure and luxuriancy near the ſea-ſhore, where the Romans uſed to indulge themſelves to a great degree in ſoftneſs and delicacy of living. The word is uſed in this ſenſe by Cicero and Virgil; but Voſſius thinks it can only be uſed in ſpeaking of Sicily, as theſe two authors did.

ACTÆA, *Aconitum Racemoſum, Herb Chriſtopher, or Baneberries*; a genus of the monogynia order, belonging to the polyandria claſs of plants.

ACTE. The elder tree

ACTIAN Games, in Roman antiquity, were ſolemn games inſtituted by Auguſtus, in memory of his victory over Marc Anthony at Actium, held every fifth year, and celebrated in honour of Apollo, ſince called Actius. Hence Actian years, an æra commencing from the battle of Actium, called the Æra of Auguſtus.

Virgil inſinuates them to have been inſtituted by Æneas; from that paſſage En. III. v. 280.

> *Actiaque Iliacis celebramus littora ludis.* Æn. iii. 250.

But this he only does by way of compliment to Auguſtus; attributing that to the hero from whom he deſcended, which was done by the emperor himſelf; as is obſerved by Servius.

ACTINIA, in zoology, a genus belonging to the order of vermes molluſca. Progreſſive motion in theſe creatures is ſo ſlow, that it is difficult to perceive any, as they ſcarce advance the length of one inch in an hour. It would ſeem they do not all produce, when handled, the painful ſenſation which had acquired them the name of ſea-nettles. They are viviparous, feed on ſhell fiſh, open their mouths more or leſs according to the ſize of the prey they have to deal with, and then reject the ſhell through the ſame aperture. When the mouth is open, all the tentacula of the actinia may be ſeen, reſembling in that ſituation a full-blown flower, which has given it the denomination of the flower-fiſh.

ACTION, in a general ſenſe, implies nearly the ſame thing with Act. Grammarians, however, obſerve ſome diſtinction between *action* and *act*; the former being generally reſtricted to the common or ordinary tranſactions, whereas the latter is uſed to expreſs thoſe which are remarkable. Thus, we ſay it is a good *action* to comfort the unhappy; it is a generous *act* to deprive ourſelves of what is neceſſary, for their ſake. The wiſe man propoſes to himſelf an honeſt end in all his *actions*; a prince ought to mark every day of his life with ſome act of greatneſs. The abbé Girard makes a further diſtinction between the words *action* and *act*. The former, according to him, has more relation to the power that acts than the latter; whereas the latter has more relation to the effect produced than the former: and hence the one is properly the attribute of the other. Thus we may properly ſay, "Be ſure to preſerve a preſence of mind in all your actions; and take care that they be all acts of equity."

Action, in mechanics, implies, either the effort which a body or power makes againſt another body or power, or the effect itſelf of that effort.

As it is neceſſary in works of this kind to have a particular regard to the common language of mechanics and philoſophers, we have given this double definition: but the proper ſignification of the term is the motion which a body really produces, or tends to produce, in another; that is, ſuch is the motion it would have produced, had nothing hindred its effect.

All power is nothing more than a body actually in motion, or which tends to move itſelf; that is, a body which would move itſelf if nothing oppoſed it. The action therefore of a body is rendered evident to us by its motion only; and conſequently we muſt not fix any other idea to the word action, than that of actual motion, or a ſimple tendency to motion. The famous queſtion relating to *vis viva* and *vis mortua*, owes, in all probability, its exiſtence to an inadequate idea of the word action; for had Leibnitz and his followers obſerved, that the only preciſe and diſtinct idea we can give to the word force or action, reduces it to its effect, that is, to the motion it actually produces or tends to produce, they would never have made that curious diſtinction.

Quantity of ACTION, a name given by M. de Maupertuis, in the memoirs of the Pariſian Academy of Sciences for 1744, and thoſe of Berlin for 1746, to the product of the maſs of a body by the ſpace which it runs through, and by its celerity. He lays it down as a general law, "that, in the changes made in the ſtate of a body, the quantity of action neceſſary to produce ſuch change, is the leaſt poſſible." This principle he applies to the inveſtigation of the laws of refraction, of equilibrium, &c. and even to the ways of acting employed by the Supreme Being. In this manner M. de Maupertuis attempts to connect the metaphyſics of final cauſes with the fundamental truths of mechanics, to ſhew the dependence of the colliſion of both elaſtic and hard bodies upon one and the ſame law, which before had always been referred to ſeparate laws; and to reduce the laws of motion, and thoſe of equilibrium, to one and the ſame principle.

ACTION, in ethics, denotes the external ſigns or expreſſions of the ſentiments of a moral agent.

ACTION, in poetry, the ſame with ſubject or fable. Critics generally diſtinguiſh two kinds, the principal and the incidental. The principal action is what is generally called the fable; and the incidental an epiſode.

ACTION, in oratory, is the outward deportment of the orator to the accommodation of his countenance, voice, and geſtures to the ſubject of which he is treating.

ACTION, in painting and ſculpture, is the attitude or poſition of the ſeveral parts of the face, body, and limbs of ſuch figures as are repreſented, and whereby they ſeem to be really actuated by paſſion. Thus we ſay, the action of ſuch a figure finely expreſſes the paſſions with which it is agitated: we alſo uſe the ſame expreſſions with regard to animals.

ACTION, in phyſiology, is applied to the functions of the body, whether vital, animal, or natural.

The vital functions, or actions, are thoſe which are abſolutely neceſſary to life, and without which there is no life, as the action of the heart, lungs, and arteries. On the action and reaction of the ſolids and fluids on each other, depend the vital functions. The pulſe and reſpiration are the external ſigns of life. Vital diſeaſes are all thoſe which hinder the influx of the venous blood into the cavities of the heart, and the expulſion of the arterial blood from the ſame. The natural functions are thoſe which are inſtrumental in repairing the ſeveral loſſes which the body ſuſtains; for life is deſtructive of itſelf, its very offices occaſioning a perpetual waſte. The manducation of food, the deglutition and digeſtion thereof, alſo the ſeparation and diſtribution of the chyle and excrementitious parts, &c. are under the head of natural functions, as by theſe our aliment is converted into our nature. They are neceſſary to the continuance of our bodies. The animal functions are thoſe which we perform at will, as muſcular motion, and all the voluntary actions of the body: they are thoſe which conſtitute the ſenſes of touch, taſte, ſmell, ſight, hearing; perception, reaſoning, imagination, memory, judgment, and affections of the mind. Without any, or all of them, a man may live, but not ſo comfortably as with them.

ACTION, in commerce, is a term uſed abroad for a certain part or ſhare of a public company's capital ſtock. Thus, if a company has 400,000 livres capital ſtock, this may be divided into 400 actions, each conſiſting of 1000 livres. Hence a man is ſaid to have two, four, &c. actions, according as he has the property of two, four, &c. 1000 livres capital ſtock. The transferring of actions abroad is performed much in the ſame manner as ſtocks are with us.

ACTION, in law, is a demand made before a judge for obtaining what we are legally entitled to demand, and is more commonly known by the name of law-ſuit, or proceſs.

ACTIONARY, or ACTIONIST, a proprietor of ſtock in a trading company.

ACTIONS, among merchants, ſometimes ſignify moveable effects; and we ſay the merchant's creditors have ſeized on all his actions, when we mean that they have taken poſſeſſion of all his active debts.

ACTIVE, denotes ſomething that communicates action or motion to another; in which acceptation it ſtands oppoſed to paſſive.

ACTIVE, in grammar, is applied to ſuch words as expreſs action; and is therefore oppoſed to paſſive. The active performs the action, as the paſſive recites it. Thus we ſay, a verb *active*, a conjugation *active*, &c. or an *active* participle. See Syſtem of GRAMMAR.

ACTIVE *Power*, in metaphyſics, the power of executing any work or labour; in contradiſtinction to ſpeculative powers, or the powers of ſeeing, hearing, remembering, judging, reaſoning, &c.

ACTIVE *Principles*, in chemiſtry, ſuch as are ſuppoſed to act without any aſſiſtance from others; as mercury, ſulphur, &c.

ACTIVITY, in general, denotes the power of acting, or the active faculty.

Sphere of ACTIVITY, the whole ſpace in which the virtue, power, or influence, of any object, is exerted.

ACTIUS, in mythology, a ſurname of Apollo, from Actium, where he was worſhipped.

ACTOR, in general, ſignifies a perſon who acts or performs ſomething.

ACTOR, among Civilians, the proctor or advocate in civil courts or cauſes: as, *Actor eccleſiæ* has been ſometimes uſed for the advocate of the church; *actor dominicus* for the lord's attorney; *actor villæ*, the ſteward or head bailiff of a village.

ACTOR, in the drama, is a perſon who repreſents ſome part or character upon the theatre.

ACTORUM TABULÆ, in antiquity, were tables inſtituted by Servius Tullius, in which the births of children were regiſtered.

ACTRESS, in a general ſenſe, implies a female who acts or performs ſomething.

ACTRESS, in the drama, a female performer. Women actors were unknown to the ancients, among whom men always performed the female character; and hence one reaſon for the uſe of maſks among them.

ACTUAL, ſomething that is real and effective, or that exiſts truly and abſolutely. Thus philoſophers uſe the terms *actual* heat, *actual* cold, &c. in oppoſition to virtual or potential. Hence, among phyſicians, a red-hot iron, or fire, is called an *actual* cautery; in diſtinction from cauteries, or cauſtics, that have the power of producing the ſame effect upon the animal ſolids as actual fire, and are called potential cauteries.

ACTUAL *Sin*, that which is committed by the perſon himſelf; in oppoſition to original ſin, or that which he contracted from being a child of Adam.

ACTUARIÆ NAVES, a kind of ſhips among the Romans, chiefly deſigned for ſwift ſailing.

ACTUARIUS, or ACTARIUS, a notary or officer appointed to write the acts or proceedings of a court, or the like. In the Eaſtern empire, the actuarii were properly officers who kept the military accounts, received the corn from the *ſuſceptores*, or ſtorekeepers, and delivered it to the ſoldiers.

ACTUATE, to bring into act, or put a thing in action. Thus an agent is ſaid, by the ſchoolmen, to *actuate* a power, when it produces an act in a ſubject. And thus the mind may be ſaid to *actuate* the body.

ACTUS, in ancient architecture, a meaſure in length equal to 120 Roman feet. In ancient agriculture, the word ſignified the length of one furrow, or the diſtance a plough goes before it turns.

ACTUS *Minimus*, was a quantity of land 120 feet in length, and four in breadth.

ACTUS *Major*, or ACTUS *Quadratus*, a piece of ground in a ſquare form, whoſe ſide was equal to 120 feet, equal to half the jugerum.

ACTUS *Intervicenalis*, a ſpace of ground four feet in breadth, left between the lands as a path or way.

ACUANITES, in eccleſiaſtical hiſtory, the ſame with thoſe called more frequently manichees. They took the name from Acua, a diſciple of Thomas, one of the twelve apoſtles.

ACUBENE, in aſtronomy, a name given by ſome to a ſtar in the ſouthern claw of Cancer.

ACUHYATLI, in zoology, a large American ſerpent, of a poiſonous nature, uſually called CUCURUCU, or CURUCUCA.

ACUITION, or ACUTITION, in grammar, denotes a ſyllable to be pronounced or marked with an acute accent. In medicine and chemiſtry it ſignifies an increaſe of ſharpneſs, or acidity. In a general ſenſe, acuition implies ſharpneſs.

ACULEATE, or ACULEATI, a term applied to any plant or animal armed with prickles.

ACULEI, the prickles of animals or of plants.

ACULER, in the manege, is uſed for the motion of a horſe, when, in working upon volts, he does not go far enough forward at every time or motion, ſo that his ſhoulders embrace or take in too little ground, and his croupe comes too near to the centre of the volt. Horſes are naturally inclined to this fault in making demi-volts.

ACUMEN, in muſic, ſignifies the ſound produced by intention, or raiſing the voice.

ACUMINA, in antiquity, a kind of military omen, moſt generally ſuppoſed to have been taken from the points or edges of darts, ſwords, or other weapons.

ACUPUNCTURE, the name of a ſurgical operation among the Chineſe and Japaneſe, which is performed by pricking the part affected with a ſilver needle. They employ this operation in head-achs, lethargies, convulſions, colics, &c.

ACUS, in ichthyology, the name of a long and ſlender ſea-fiſh, which has ſo little fleſh about it, that it is not regarded as eatable. It is common in the Mediterranean, and is called by the Venetian fiſhermen *biſca*, that is, the viper-fiſh. Of this fiſh there are two ſpecies, one of which is called in Engliſh, the needle, or tobacco-pipe fiſh, and the other the gar-fiſh.

ACUTE, an epithet applied to ſuch things as terminate in a ſharp point or edge. And in this ſenſe it ſtands oppoſed to obtuſe.

ACUTE *Angle*, in geometry, is that which is leſs than a right angle, or which does not ſubtend 90 degrees.

ACUTE-*angled Triangle*, is a triangle whoſe three angles are all acute.

ACUTE-*angled Cone* is, according to the ancients, a right cone, whoſe axis makes an acute angle with its ſide.

ACUTE, in muſic, is applied to a ſound or tone that is ſharp or high, in compariſon of ſome other tone. In this ſenſe, *acute* ſtands oppoſed to *grave*.

ACUTE *Accent*, in grammar. See Syſtem of GRAMMAR.

ACUTE *Diſeaſes*, ſuch as come ſuddenly to a criſis. This term is uſed for all diſeaſes which do not fall under the head of chronic diſeaſes.

ACUTELLA, in botany, a name uſed by ſome to expreſs the common Adonis, famous for its ſpreading and tough root.

ACUTIATOR, in writers of the barbarous ages, denotes a perſon that whets or grinds cutting inſtruments. In the ancient armies there were acutiatories, a kind of ſmiths, retained for whetting or keeping the arms ſharp.

ACYROLOGIA, an expreſſion applied figuratively, which implies more than is ſaid, in order to raiſe doubts in the breaſt of the perſon ſo addreſſed.

AD, a Latin prepoſition, originally ſignifying *to*, and frequently uſed in compoſition both with and without the *d*, to expreſs the relation of one thing to another.

AD *Beſtias*, in antiquity, is the puniſhment of criminals condemned to be thrown to wild beaſts.

AD *Hominem*, in logic, a kind of argument drawn from the principles or prejudices of thoſe with whom we argue.

AD *Ludos*, in antiquity, a ſentence upon criminals among the Romans, whereby they were condemned to entertain the people by fighting either with wild beaſts, or with one another, and thus executing juſtice upon themſelves.

AD *Metalla*, in antiquity, the puniſhment of ſuch criminals as were condemned to the mines, among the Romans; and therefore called *Metallici*.

AD *Valorem*, a term chiefly uſed in ſpeaking of the duties or cuſtoms paid for certain goods: the duties on ſome articles are paid by the number, weight, meaſure, tale, &c. and others are paid *ad valorem*, that is, according to their value.

ADAGE, a proverb, or ſhort ſentence, containing ſome wiſe obſervation or popular ſaying.

ADAGIO, in muſic. Adverbially, it ſignifies ſoftly, leiſurely; and is uſed to denote the ſloweſt of all times. Uſed ſubſtantively, it ſignifies a ſlow movement. Sometimes this word is repeated, as *adagio, adagio*, to denote a ſtill greater retardation in the time of the muſic.

ADAL, the pure medicinal virtue of vegetables, ſeparated from the impure.

ADALIDES, in the Spaniſh policy, are officers of juſtice, for matters touching the military forces.

ADAM's APPLE, a name given to a ſpecies of citrus.

ADAMANT, a name ſometimes given to the diamond. It is likewiſe applied to the ſcoriæ of gold, the magnet, &c.

ADAMIC EARTH, a name given to common red clay, alluding to that ſpecies of earth of which the firſt man is ſuppoſed to have been made.

ADAMI POMUM, in anatomy, a protuberance in the forepart of the throat, formed by the os hyoides. It is thought to be ſo called upon a ſtrange conceit, that a piece of the forbidden apple, which Adam eat, ſtuck by the way, and occaſioned it.

ADAMITES, in eccleſiaſtical hiſtory, the name of a ſect of ancient heretics, ſuppoſed to have been a branch of the Baſilidians and Carpocratians.

Epiphanius tells us, that they were called Adamites from their pretending to be re-eſtabliſhed in the ſtate of innocence, and to be ſuch as Adam was at the moment of his creation, whence they ought to imitate him in his nakedneſs. They deteſted marriage; maintaining, that the conjugal union would never have taken place upon earth had ſin been unknown.

ADAMUS, the philoſopher's ſtone is ſo called by alchemiſts; they ſay it is an animal, and that it has carried its inviſible Eve in its body, ſince the moment they were united by the Creator.

ADANSONIA, ETHIOPIAN SOUR-GOURD, MONKIES-BREAD, or AFRICAN CALABASH-TREE, a genus of the monodelphia order, belonging to the polyandria claſs of plants. There is at preſent but one known ſpecies belonging to this genus, the baobab, which is perhaps the largeſt production of the whole vegetable kingdom. It is a native of Africa.

ADAPTERS, or ADOPTERS, among chemiſts, are veſſels in the form of hollow globes, having two mouths or apertures diametrically oppoſite to each other, one of which admits the neck of the retort, and the other is received either by the mouth of another adopter, or into the mouth of the receiver.

ADAR, the name of a Hebrew month, anſwering to the end of February and beginning of March, the 12th of their ſacred, and 6th of their civil year. On the 7th day of it the Jews keep a feaſt for the death of Moſes; on the 13th, they have the feaſt of Eſther; and on the 14th, they celebrate the feaſt of Purim, for their deliverance from Haman's conſpiracy. As the lunar year, which the Jews followed in their calculations, is ſhorter than the ſolar by about 11 days, which at the end of three years make a month, they then intercalate a 13th month, which they call *Veadar*, or the *ſecond Adar*.

ADARCE, a kind of concreted ſalts found on reeds and other vegetables, and applied by the ancients as a remedy in ſeveral cutaneous diſeaſes.

ADARCON, in Jewiſh antiquity, a gold coin mentioned in Scripture, worth about 15s. ſterling.

ADARME, in commerce, a ſmall weight in Spain, which is alſo uſed at Buenos-Aires, and in all Spaniſh America. It is the 16th part of an ounce, which at Paris is called the demi-gros. But the Spaniſh ounce is ſeven per cent. lighter than that of Paris. Stephens renders it in Engliſh by a dram.

ADATAIS, ADATSI, or ADATYS, in commerce, a muſlin or cotton-cloth, very fine and clear, of which the piece is ten French ells long, and three quarters broad. It comes from the Eaſt-Indies; and the fineſt is made at Bengal.

ADCORDABILIS DENARII, in old law books, ſignify money paid by the vaſſal to his lord, upon the ſelling or exchanging of a feud.

ADCRESCENTES, among the Romans, denoted a kind of ſoldiery, entered in the army, but not yet put on duty; from theſe the ſtanding forces were recruited.

ADDEPHAGIA, in medicine, a term uſed by ſome phyſicians, for gluttony, or a voracious appetite.

ADDER, in zoology, a name for the Viper.

Sea- ADDER, the Engliſh name of a ſpecies of Syngnathus.

Water-ADDER, a name given to the coluber natrix.

ADDER-*ſtung*, is uſed in reſpect of cattle, when ſtung with any kind of venomous reptiles, as adders, ſcorpions, &c. or bit by a hedge-hog or ſhrew. For the cure of ſuch bites, ſome uſe an ointment made of dragon's blood, with a little barley-meal, and the whites of eggs.

ADDEXTRATORES, in the court of Rome, the pope's mitre-bearers, ſo called, according to Ducange, becauſe they walk at the Pope's right hand, when he rides to viſit the churches.

ADDICE, or ADZE, a kind of crooked ax uſed by ſhip-wrights, carpenters, coopers, &c.

ADDICTI, in antiquity, a kind of ſlaves, among the Romans, adjudged to ſerve ſome creditor whom they could not otherwiſe ſatisfy, and whoſe ſlaves they became till they could pay or work out the debt.

ADDICTIO, or ADDICTION, among the Romans, was the making over goods to another, either by ſale, or by legal ſentence; the goods ſo delivered were called *bona addicta*. Debtors were ſometimes delivered over in the ſame manner; and thence called *ſervi addicti*.

ADDICTIO IN DIEM, among the Romans, the adjudging a thing to a perſon for a certain price, unleſs by ſuch a day the owner, or ſome other, give more for it.

ADDITAMENT, ſomething added to another. Thus phyſicians call the ingredients added to a medicine already compounded, additaments.

ADDITION, in a general ſenſe, is the joining together or uniting two or more things, or augmenting a thing by the acceſſion of others thereto.

ADDITION, in arithmetic, algebra, &c. See Syſtems of ARITHMETIC and ALGEBRA.

ADDITION, in muſic, a dot marked on the right ſide of a note, ſignifying, that it is to be ſounded or lengthened half as much more as it would have been without ſuch mark.

ADDITION, in law, is that name or title which is given to a man over and above his proper name and ſurname, to ſhew of what eſtate, degree, or myſtery he is; and of what town, village, or country.

ADDITIONS *of Eſtate*, or *Quality*, are yeoman, gentleman, eſquire, and ſuch like.

ADDITIONS *of Degree*, are thoſe we call names of dignity; as knight, lord, earl, marquis, and duke.

ADDITIONS *of Myſtery*, are ſuch as ſcrivener, painter, maſon, and the like.

ADDITIONS *of Place*, are, of Thorp, of Dale, of Woodſtock. Where a man hath houſehold in two places, he ſhall be ſaid to dwell in both; ſo that his addition in either may ſuffice. Knave was anciently a regular addition. By ſtat. 1. Hen. V. cap. 5.

it was ordained, that in ſuch ſuits or actions where proceſs of outlawry lies, ſuch addition ſhould be made to the name of the defendant, to ſhew his eſtate, myſtery, and place where he dwells; and that the writs not having ſuch additions ſhall abate if the defendant take exception thereto; but not by the office of the court. The reaſon of this ordinance was, that one man might not be troubled by the outlawry of another; but by reaſon of the certain addition, every perſon might bear his own burden.

ADDITIONS, in diſtilling, a name given to ſuch things as are added to the waſh, or liquor, while in a ſtate of fermentation, in order to improve the vinocity of the ſpirit, procure a larger quantity of it, or give it a particular flavour. All things, of whatever kind, thus added in the time of fermentation, are called by thoſe of the buſineſs who ſpeak moſt intelligently, *additions*; but many confound them with things of a very different nature, under the name of ferments.

ADDITIONS, in heraldry, ſignify things added to a coat of arms, as marks of honour. Among thoſe we reckon, bordure, quarter, canton, gyron, pile, &c.

ADDRESS, in a general ſenſe, is uſed for ſkill and good management, and of late has been adopted from the French. It is uſed alſo in commerce, as ſynonymous with direction to a perſon or place. The word is formed of the French verb *adreſſer*, to direct any thing to a perſon.

ADDUCENT *Muſcles*, or ADDUCTORS, in anatomy, thoſe muſcles which draw one part of the body towards another. See Syſtem of ANATOMY.

ADEB, in commerce, the name of a large Egyptian weight, uſed principally for rice, and conſiſting of 210 okes, each of three rotolos, a weight of about two drams leſs than the Engliſh pound. But this is no certain weight, for at Roſetto the adeb is only 150 okes.

ADELIA, a genus of the monadelphia order, belonging to the diœcia claſs of plants. Of this genus there are three ſpecies; the bernardia, the ricinella, and acidoton, for which we have no proper names in Engliſh. They are natives of Jamaica, and are akin to the rhicinus, or croton, and may be propagated in in hot-beds from ſeeds procured from Jamaica. For the generic characters, ſee Syſtem of BOTANY.

ADELPHIANI, in church hiſtory, a ſect of ancient heretics, who faſted always on Sundays.

ADELSCALC, in ancient cuſtoms, denotes a ſervant of the king. The word is alſo written adelſchalche, and adelſcalcus. It is compounded of the German *anel*, or *edel*, "noble," and *ſcalc*, "ſervant." Among the Bavarians, *adelſcalcs* appear to have been the ſame with royal thanes among the Saxons, and thoſe called *miniſtri regis* in ancient charters.

ADEMPTION, in the civil law, implies the revocation of a grant, donation, or the like.

ADENANTHERA, BASTARD FLOWER-FENCE, a genus of the monogynia order, belonging to the decandria claſs of plants. In the natural method, it belongs to the 33d order, Lomentaceæ. Only one ſpecies of this plant is known in Britain: but there is a variety with ſcarlet ſeeds; which, however, is rare, and grows very ſlowly. It is a native of India, and riſes to a conſiderable height. It is as large as the tamarind tree; ſpreads its branches wide on every ſide, and makes a fine ſhade; for which reaſon, it is frequently planted by the inhabitants in their gardens, or near their habitations. The leaves of this tree are doubly winged, the flowers of a yellow colour, and diſpoſed in a long bunch. Theſe are ſucceeded by long twiſted membranaceous pods, incloſing ſeveral hard compreſſed ſeeds, of a beautiful ſcarlet, or ſhining black colour. This plant muſt be raiſed in a hot bed, and kept during winter in a ſtove.

ADENOGRAPHY, that part of anatomy which treats of the glandular parts. See Syſtem of ANATOMY.

ADENOIDES, glandulous, or of a glandular form; an epithet applied to the Proſtatæ.

ADENOLOGY, the ſame with ADENOGRAPHY.

ADENOS, a kind of cotton, otherwiſe called marine cotton. It comes from Aleppo by the way of Marſeilles, where it pays 20 per cent. duty.

ADEONA, in mythology, the name of a goddeſs invoked by the Romans when they ſet out upon a journey.

ADEPHAGIA, in mythology, the goddeſs of gluttony, to whom the Sicilians paid religious worſhip.

ADEPS, in anatomy, the fat found in the abdomen. It alſo ſignifies animal fat of any kind.

ADEPTS, a term given to alchemiſts who pretended to have found the panacea, or philoſophers ſtone.

ADEQUATE, in a general ſenſe, implies ſomething exactly correſponding with another.

ADEQUATE *Ideas*, are thoſe which perfectly repreſent all the parts and properties of the object.

All ſimple ideas are adequate or perfect, becauſe they are repreſented intire.

On the contrary, the ideas of ſubſtances which are not formed at the pleaſure of the mind, but derived from properties diſcovered by experience, are inadequate or imperfect, becauſe they are only acquainted with ſome of the properties. See Syſtem of LOGIC.

ADES, or HADES, denotes the inviſible ſtate. In the heathen mythology, it comprehends all thoſe regions that lie beyond the river Styx, viz. Erebus, Tartarus, and Elyſium.

ADESSENARIANS, ADESSENARII, in church hiſtory, a ſect of Chriſtians who hold the real preſence of Chriſt's body in the euchariſt, though not by way of tranſubſtantiation.

ADFILIATION, a Gothic cuſtom, whereby the children of a former marriage are put upon the ſame footing with thoſe of the ſecond. This is alſo called *unio prolium*, and ſtill retained in ſome parts of Germany.

ADHA, a feſtival which the Mahometans celebrate on the 10th day of the month *Dhoulhegiat*, which is the 12th and laſt of their year. This month being particularly deſtined for the ceremonies which the pilgrims obſerve at Mecca, it takes its name from thence, for the word ſignifies the month of pilgrimage. On that day they ſacrifice with great ſolemnity, at Mecca, and no where elſe, a ſheep, which is called by the ſame name as the feſtival itſelf. The Turks commonly call this feſtival the Great Beiram, to diſtinguiſh it from the leſſer, which ends their faſt, and which the Chriſtians of the Levant call the Eaſter of the Turks. The Mahometans celebrate this feſtival, out of the city of Mecca, in a neighbouring valley; and ſometimes they ſacrifice a camel on the occaſion.

ADHESION, in a general ſenſe, implies the ſticking or adhering of bodies together.

ADHESION, in philoſophy, the ſame as coheſion.

ADHESION, in anatomy, a term for one part ſticking to another, which in a natural ſtate are ſeparate. For the moſt part, if any of thoſe parts in the thorax or belly lie in contact, and inflame, they grow together. The lungs very frequently adhere to the pleura.

ADHIL, in aſtronomy, a ſtar of the ſixth magnitude, upon the garment of Andromeda, under the laſt ſtar in her foot.

ADHOA, in ancient cuſtoms, denotes what we otherwiſe call relief. In which ſenſe we ſometimes alſo find the word written *adhoa*, *adhoamentum*, and *adhogamentum*.

ADIANTHIUM, in botany, maiden-hair; a genus of the order of filices, belonging to the cryptogamia claſs of plants.

ADIAPHORISTS, in church hiſtory, a name importing lukewarmneſs, given, in the 16th century, to the moderate Lutherans, who embraced the opinions of Melancthon, whoſe diſpoſition was vaſtly more pacific than that of Luther.

ADIAPHOROUS, ADIAPHORUS, a name given by Mr. Boyle to a kind of ſpirit diſtilled from tartar and ſome other vegetable bodies, and which is neither acid, vinous, or urinous; but in many reſpects different from any other ſort of ſpirit.

ADJECTIVE, in grammar, a kind of noun joined with a ſubſtantive, either expreſſed or implied, to ſhew its qualities or accidents. See Syſtem of GRAMMAR.

ADJOURNMENT, the putting off a court, or other meeting, till another day. There is a difference between the adjournment and the prorogation of the parliament; the former not only being for a ſhorter time, but alſo done by the houſe itſelf; whereas the latter is an act of royal authority.

ADIPOSE, a term uſed by anatomiſts for any cell, membrane, &c. that is remarkable for its fatneſs.

ADIPSOS, ſignifies the Egyptian palm-tree.

ADIT, in a general ſenſe, the paſſage to, or entrance of, any thing.

ADIT *of a Mine*, the hole, or aperture, whereby it is entered and dug, and by which the water and ores are carried away. The term amounts to the ſame with *cuniculus* or drift, and is diſtinguiſhed from air-ſhaft. The adit is uſually made on the ſide of a hill, towards the bottom thereof, about four, five, or ſix feet high, and eight wide, in form of an arch: ſometimes cut in the rock, and ſometimes ſupported with timber, ſo conducted as that the ſole or bottom of the adit may anſwer to the bottom of the ſhaft, only ſomewhat lower, that the water may have a ſufficient current to paſs away without the uſe of the pump. Damps and the impurity of the air are the great impediments againſt driving adits above 20 or 30 fathoms, by reaſon of the neceſſity, in this caſe, of letting down air ſhafts from the day to meet the adit, which are often very expenſive, both on account of the great depth of mines, and the hardneſs of the mineral ſtrata to be cut through. The beſt remedy againſt this is that practiſed in the coal-mines near Liege, where they work their adits without air-ſhafts: the manner of which is deſcribed by Sir Robert Moray. Vide Phil. Tranſ. No. 5.

ADIT *of a Mine* is ſometimes uſed for the air-ſhaft itſelf, being a hole driven perpendicularly from the ſurface of the earth into ſome part of a mine, to give entrance to the air. To draw off the ſtanding water in winter, in deep mines, they drive up an adit, or air-ſhaft, upon which the air diſengages itſelf from the water, when it begins to run with ſuch violence as produces a noiſe equal to the burſting of a cannon, daſhes every thing in the way againſt the ſides of the mine, and looſens the very rocks at a diſtance. Ibid. No. 26.

ADJUDICATION, implies the act of adjudging, or determining, a cauſe in favour of ſome perſon.

ADJUNCT, among philoſophers, ſignifies ſomething added to another, without being any neceſſary part of it. Thus water by cloth or a ſponge, is an adjunct, but no neceſſary part of either of theſe ſubſtances.

Adjunct, in metaphyſics, ſome quality belonging to either the body or mind, whether natural or acquired. Thus, thinking is an adjunct of the mind, and growth an adjunct of the body.

Adjunct, in muſic, a word which is employed to denominate the connection or relation between the principal mode and the modes of its two fifths, which, from the intervals that conſtitute the relation between them and it, are called its adjuncts.

Adjunct is alſo uſed to ſignify a colleague, or ſome perſon aſſociated with another as an aſſiſtant.

Adjuncts, in rhetoric and grammar, ſignify certain words or things added to others, to amplify or augment the force of the diſcourſe.

Adjuncts, or **Adjoints**, in the royal academy of ſciences at Paris, denote a claſs of members, attached to the purſuit of particular ſciences. The claſs of adjuncts was created in 1716, in lieu of the eleves: they are twelve in number; two for geometry, two for mechanics, two for aſtronomy, two for anatomy, two for chemiſtry, and two for botany. The eleves not taken into this eſtabliſhment were admitted on the foot of ſupernumerary adjuncts.

ADJUTANT, in the military art, is an officer whoſe buſineſs it is to aſſiſt the major. Each battalion of foot and regiment of horſe has an adjutant, who receives the orders every night from the brigade major; which, after carrying them to the colonel, he delivers out to the ſerjeants. When detachments are to be made, he gives the number to be furniſhed by each company or troop, and aſſigns the hour and place of rendezvous. He alſo places the guards, receives and diſtributes the ammunition to the companies, &c. and, by the major's orders, regulates the prices of bread, beer, and other proviſions. The word is ſometimes uſed by the French for an *aid-du-camp*.

Adjutants *General*, among the Jeſuits, a ſelect number of fathers, who reſided with the general of the order, each of whom had a province or country aſſigned him, as England, Holland, &c. and their buſineſs was to inform the father-general of ſtate occurrences in ſuch countries. To this end they had their correſpondents delegated, emiſſaries, viſitors, regents, provincials, &c.

ADJUTORIUM, a term uſed by phyſicians for any medicine in a preſcription but the capital one.

ADLEGATION, in the public law of the German empire, a right claimed by the ſtates of the empire of adjoining plenipotentiaries, in public treaties and negociations, to thoſe of the emperors, for the tranſacting of matters which relate to the empire in general. In which ſenſe adlegation differs from legation, which is the right of ſending ambaſſadors on a perſon's own account.

ADLOCUTION, *Adlocutio*, in antiquity, is chiefly underſtood of ſpeeches made by Roman generals to their armies, to encourage them before a battle. We frequently find theſe adlocutions expreſſed on medals by the abbreviature, Adlocut. Coh.

ADMANUENSES, in ancient law books, denote perſons who ſwore by laying their hands on the book. In which ſenſe, *admanuenſes* amount to the ſame with laymen; and ſtand oppoſed to clerks, who were forbid to ſwear on the book, their word being to be reputed as their oath; whence they were alſo denominated *fide digni*.

ADMEASUREMENT, *Admenſuratio*, in law, a writ which lies for the bringing thoſe to reaſon, or mediocrity, who uſurp more of any thing than their ſhare. This writ lies in two caſes; termed,

Admeasurement *of Dower*, *Admenſuratio dotis*, where the widow of the deceaſed holds more from the heir, or his guardian, on account of her dower, than of right belongs to her. And,

Admeasurement *of Paſture*, *Admenſuratio paſturæ*; this lies between thoſe who have common of paſtures appendant to their freehold, or common by vicinage, in caſe any of them ſurcharge the common with more cattle than they ought.

ADMINICLE, a term uſed chiefly in old law books, to imply an aid, help, aſſiſtance, or ſupport.

ADMINICULATOR, an ancient officer of the church, whoſe buſineſs it was to attend to and defend the cauſe of the widows, orphans, and others deſtitute of help.

ADMINISTRATION, in general, the government, direction, or management of affairs, and particularly the exerciſe of diſtributive juſtice; among eccleſiaſtics, it is often uſed to expreſs the giving or diſpenſing the ſacraments, &c.

ADMINISTRATOR, in law, he to whom the ordinary commits the adminiſtration of the goods of a perſon deceaſed, in default of an executor. An action lies for, or againſt an adminiſtrator, as for or againſt an executor; and he ſhall be accountable to the value of the goods of the deceaſed, and no farther; unleſs there be waſte, or other abuſe chargeable on him. If the adminiſtrator dies, his executors are not adminiſtrators; but the court is to grant a new adminiſtration. If a ſtranger, who is neither adminiſtrator or executor, take the goods of the deceaſed, and adminiſter, he ſhall be charged and ſued as an executor, not as an adminiſtrator. The origin of adminiſtration is derived from the civil law. Their eſtabliſhment in England is owing to a ſtatute made in the 31ſt year of Edw. III. till then, no office of this kind was known beſide that of executor: in caſe of a want of which, the ordinary had the diſpoſal of goods of perſons inteſtate, &c.

Administrator is ſometimes uſed for the preſident of a province; for a perſon appointed to receive, manage, and diſtribute the revenues of an hoſpital or religious houſe; for a prince who enjoys the revenues of a ſecularized biſhopric; and for the regent of a kingdom during a minority of the prince, or a vacancy of the throne.

ADMIRABILIS Sal, the ſame with Glauber's ſalt.

ADMIRAL, a great officer or magiſtrate, who has the government of a navy, and the hearing of all maritime cauſes.

Du Cange aſſures us, that the Sicilians were the firſt, and the Genoeſe the next, who gave the denomination of Admiral to the commanders of their naval armaments; and that they took it from the Saracen or Arabic Emir, a general name for every commanding officer. As for the exact time when the word was introduced among us, it is uncertain; ſome think it was in the reign of Edward I. Sir Henry Spelman is of opinion that it was firſt uſed in the reign of Henry III. becauſe neither the laws of Oleron made in 1266, nor Bracton, who wrote about that time, make any mention of it; and that the term admiral was not uſed in a charter in the eighth of Henry III. wherein he granted this office to Richard de Lacey, by theſe words Maritimam Angliæ; but in the 56th year of the ſame reign, not only the hiſtorians, but the charters themſelves, very frequently uſed the word Admiral.

Anciently there were generally three or four admirals appointed in the Engliſh ſeas, all of them holding the office *durante bene placito:* and each of them having particular limits under their charge and government; as admirals of the fleets of ſhips, from the mouth of the Thames northward, ſouthward, or weſtward. Beſides theſe, there were admirals of the Cinque Ports, as in the reign of Edward III. when one William Latimer was ſtyled *admiralis quinque portuum*; and we ſometimes find that one perſon has been admiral of the fleets to the ſouthward, northward, and weſtward: but the title of *admiralis Angliæ* was not frequent till the reign of Henry IV. when the king's brother had that title given him, which in all commiſſions afterwards was granted to the ſucceeding admirals. It may be obſerved, that there was a title above that of admiral of England, which was, *locum-tenens regis ſuper mare*, the king's lieutenant-general of the ſea; this title we find mentioned in the reign of Richard II. Before the uſe of the word admiral was known, the title of *cuſtos maris* was made uſe of.

Lord High **Admiral** *of England*, in ſome ancient records called *capitanus maritimarum*, an officer of great antiquity and truſt, as appears by the laws of Oleron, ſo denominated from the place they were made at by Richard I. The firſt title of *Admiral of England*, expreſsly conferred upon a ſubject, was given by patent of Richard II. to Richard Fitz-Allen, jun. earl of Arundel and Surrey; for thoſe who before enjoyed this office were ſimply termed admirals, though their juriſdiction ſeems as large, eſpecially in the reign of Edward III. when the court of admiralty was firſt erected.

This great officer has the management of all maritime affairs, and the government of the royal navy, with power of deciſion in all maritime caſes both civil and criminal: he judges of all things done upon or beyond the ſea, in any part of the world; upon the ſea-coaſts, in all ports and havens, and upon all rivers below the firſt bridge from the ſea. By him, vice-admirals, rear-admirals, and all ſea-captains, are commiſſioned; all deputies for particular coaſts, and coroners to view dead bodies found on the ſea-coaſts, or at ſea: he alſo appoints the judges for his court of admiralty, and may impriſon, releaſe, &c. All ports and havens are *infra corpus comitatus*, and the admiral hath no juriſdiction of any thing done in them. Between high and low water-mark, the common-law and the high-admiral have juriſdiction by turns, one upon the water, and the other upon the land.

The lord-admiral has power, not only over the ſeamen ſerving in his ſhips of war, but over all other ſeamen, to arreſt them for the ſervice of the ſtate; and, if any of them run away, without leave of the admiral, he hath power to make a record thereof, and certify the ſame to the ſheriffs, mayors, bailiffs, &c. who ſhall cauſe them to be apprehended and impriſoned.

To the lord high-admiral belong all penalties and amercements of all tranſgreſſions at ſea, on the ſea-ſhore, in ports and havens, and all rivers below the firſt bridge from the ſea; the goods of pirates and felons condemned or enſlaved, ſea-wrecks, goods floating on the ſea, or caſt on the ſhore (not granted to lords of manors adjoining to the ſea), and a ſhare of lawful prizes; alſo all great fiſhes, commonly called *royal fiſhes*, except whales and ſturgeons: to which add, a ſalary of 7000l. a year.

In ſhort, this is ſo great an office, in point of truſt, honour, and profit, that it has been uſually given to princes of the blood, or the moſt eminent perſons among the nobility. We have had no high admiral for ſome years; the office being put in commiſſion, or under the adminiſtration of the lords commiſſioners of the admiralty, who by ſtatute have the ſame power and authority as the lord high admiral.

ADMIRAL alſo implies the commander in chief of any ſingle fleet or ſquadron; or, in general, any flag-officer whatever. The commander of a fleet carries his flag at the main-top-maſt head.

ADMIRAL is alſo an appellation given to the moſt conſiderable ſhip of a fleet of merchant-men, or of the veſſels employed in the cod-fiſhery of Newfoundland. This laſt has the privilege of chooſing what place he pleaſes on the ſhore to dry his fiſh; gives proper orders, and appoints the fiſhing-places to thoſe who come after him; and as long as the fiſhing-ſeaſon continues, he carries a flag on his main-maſt.

Vice **ADMIRAL** is the commander of the ſecond ſquadron, and carries his flag at the mizen-top-maſt head.

Vice **ADMIRAL** is alſo an officer appointed by the lords commiſſioners of the admiralty. There are ſeveral of theſe officers eſtabliſhed in different parts of Great Britain, with judges and martials under them, for executing juriſdiction within their reſpective limits. Their decrees, however, are not final, an appeal lying to the court of admiralty in London.

Rear **ADMIRAL** is the commander of the third ſquadron, and carries his flag at the fore-top-maſt head.

ADMIRAL, in zoology, the Engliſh name of a ſpecies of the voluta, a ſhell-fiſh belonging to the order of vermes teſtacea.

ADMIRALTY properly ſignifies the office of lord high-admiral, whether diſcharged by one ſingle perſon, or by joint commiſſioners called *lords of the admiralty*.

ADMIRALTY *Court*. See Court of ADMIRALTY.

ADMIRATION, in grammar, a note or character marked thus! and intimating ſomething worthy to be admired or wondered at.

ADMITTENDO, CLORICO, a writ iſſued out of the common pleas and granted to him who hath recovered his right of preſentation againſt the biſhop.

ADMONITION, in eccleſiaſtical affairs, a part of diſcipline much uſed in the ancient church. It was the firſt act, or ſtep, towards the puniſhment or expulſion of delinquents. In caſe of private offences, it was performed according to the evangelical rule, privately: in caſe of public offence, openly, before the church. If either of thoſe ſufficed for the recovery of the fallen perſon, all further proceedings in the way of cenſure ceaſed: if they did not, recourſe was had to excommunication.

ADMONITIO *Fuſtium*, among the Romans, a military puniſhment, not unlike our whipping, only it was performed with vine-branches.

ADMORTIZATION, in the feudal cuſtoms, the reduction of the property of lands or tenements to mortmain.

ADNATA, in anatomy, one of the coats of the eye, which is alſo called conjunctiva and albuginea.

ADNATA, is alſo uſed for any hair, wool, or the like, which grows upon animals or vegetables.

ADNATA, or *Adnaſcentia*, among gardeners, denote thoſe offſets, which, by a new germination under the earth, proceed from the lily, narciſſus, hyacinth, and other flowers, and afterwards grow to true roots. French call them *cayeux*, "ſtalks."

ADNOUN is uſed by ſome grammarians to expreſs what we more uſually call an adjective.

ADOLESCENCE, the eſtate of growing youth; or that period of a perſon's age commencing from his infancy, and terminating at his full ſtature or manhood. The word is formed of the Latin *adoleſcere*, to grow. The ſtate of adoleſcenſe laſts ſo long as the fibres continue to grow, either in magnitude or firmneſs. The fibres being arrived at the degree of firmneſs and tenſion ſufficient to ſuſtain the parts, no longer yield or give way to the efforts of the nutritious matter to extend them; ſo that their farther accretion is ſtopped, from the very law of their nutrition.

ADONAI, one of the names of the ſupreme Being in the Scriptures. The proper meaning of the word is *my Lords*, in the plural number; as *Adoni is my Lord*, in the ſingular. The Jews, who either out of reſpect, or ſuperſtition, do not pronounce the name of *Jehovah*, read *Adonai* in the room of it, as often as they meet with Jehovah in the Hebrew text. But the ancient Jews were not ſo ſcrupulous; nor is there any law which forbids them to pronounce the name of God. Calmet.

ADONAIS, a name given by ancient botaniſts to the flower now called anemony.

ADONIA, in antiquity, ſolemn feaſts in honour of Venus, and in memory of her beloved Adonis.

ADONIDES, a name given to botaniſts who deſcribed or made catalogues of plants cultivated in any particular place.

ADONIS, *Birds-eye*, or *Pheaſants-eye*; a genus of the polyandria order, belonging to the polygynia claſs of plants. It is aſſociated with the *Multiſiliquæ*, or 26th Nat. Order.

ADOPTIANI, in church-hiſtory, a ſect of ancient heretics, followers of Felix of Urgel, and Elipand of Toledo, who, towards the end of the eighth century, advanced the notion, that Jeſus Chriſt, in his human nature, is the Son of God, not by nature, but by adoption.

ADOPTION, an act by which any one takes another into his family, owns him for his ſon, and appoints him for his heir.

The cuſtom of adoption was very common among the ancient Greeks and Romans: yet it was not practiſed, but for certain cauſes expreſſed in the laws, and with certain formalities uſual in ſuch caſes. It was a ſort of imitation of nature, intended for the comfort of thoſe who had no children: wherefore he that was to adopt was to have no children of his own, and to be paſt the age of getting any; nor were eunuchs allowed to adopt, as being under an actual impotency of begetting children; neither was it lawful for a young man to adopt an elder, becauſe that it would have been contrary to the order of nature; nay, it was even required that the perſon who adopted ſhould be eighteen years older than his adopted ſon, that there might at leaſt appear a probability of his being the natural father.

Among the Greeks it was called *υιοτης*, *filiation*. It was allowed to ſuch as had no iſſue of their own; excepting thoſe who were not *κυριοι εαυτων*, *their own maſters*, e. g. ſlaves, women, madmen, infants, or perſons under twenty years of age; who being incapable of making wills, or managing their own eſtates, were not allowed to adopt heirs to them. Foreigners being incapable of inheriting at Athens, if any ſuch were adopted, it was neceſſary firſt to make them free of the city.

The Romans had two forms of adoption; one before the pretor; the other at an aſſembly of the people, in the times of the commonwealth, and afterwards by a reſcript of the emperor. In the former, the natural father addreſſed himſelf to the pretor, declaring that he emancipated his ſon, reſigned all his authority over him, and conſented he ſhould be tranſlated into the family of the adopter. The latter was practiſed, where the party to be adopted was already free; and this was called *adrogation*. The perſon adopted changed all his names; aſſuming the prename, name, and ſurname, of the perſon who adopted him.

Beſides the formalities preſcribed by the Roman law, various other methods have taken place; which have given denominations to different ſpecies of adoption, among the Gothic nations, in different ages. As,

ADOPTION *by Arms*, was when a prince made a preſent of arms to a perſon, in conſideration of his merit and valour. Thus it was that the king of the Heruli was adopted by Theodoric; Athalaric by the emperor Juſtinian; and Coſroes, nephew of the king of Perſia, by the emperor Juſtin. The obligation here laid on the adoptive ſon was, to protect and defend the father from injuries, affronts, &c. And hence, according to Selden, the ceremony of dubbing knights took its origin as well as name,

ADOPTION *by Baptiſm*, is that ſpiritual affinity which is contracted by god-fathers and god-children in the ceremony of baptiſm. This kind of adoption was introduced into the Greek church, and came afterwards into uſe among the ancient Franks, as appears by the Capitulars of Charlemagne.

In reality, the god-father was ſo far conſidered as adoptive father, that his god-children were ſuppoſed to be intitled to a ſhare in the inheritance of his eſtate.

ADOPTION *by Hair*, was performed by cutting off the hair of a perſon, and giving it to the adoptive father. It was thus that pope John VIII. adopted Boſon king of Arles; which, perhaps, is the only inſtance in hiſtory, of adoption, in the order of the eccleſiaſtics; a law that profeſſes to imitate nature, not daring to give children to thoſe in whom it would be thought a crime to beget any.

ADOPTION *by Teſtament*, that performed by appointing a perſon heir by will, on condition of his aſſuming the name, arms, &c. of the adopter. Of which kind we meet with ſeveral inſtances in the Roman hiſtory.

Among the Turks, the ceremony of adoption is performed by obliging the perſon adopted to paſs through the ſhirt of the adopter. Hence, among that people, to adopt, is expreſſed by the phraſe, *to draw another through my ſhirt*. It is ſaid, that ſomething like this has alſo been obſerved among the Hebrews; where the prophet Elijah adopted Eliſha for his ſon and ſucceſſor, and communicated to him the gift of prophecy, by letting fall his cloak or mantle on him. But adoption, properly ſo called, does not appear to have been practiſed among the ancient Jews: Moſes ſays nothing of it in his laws; and Jacob's adoption of his two grandſons, Ephraim and Manaſſeh, is not ſo properly an adoption, as a kind of ſubſtitution, whereby thoſe two ſons of Joſephwere allotted an equal portion in Iſrael with his own ſons.

ADOPTION is alſo uſed, in theology, for a federal act of God's free grace; whereby thoſe who are regenerated by faith, are admitted into his houſehold, and intitled to a ſhare in the inheritance of of the kingdom of heaven.

ADOPTION is alſo applied by the Greeks, to the admitting a monk, or brother, into a monaſtic community; ſometimes called *ſpiritual adoption*.

ADOPTIVE, denotes a perſon or thing adopted by another.

In eccleſiaſtical writers we find adoptive women, or ſiſters, (*adoptivæ fœminæ, or ſorores*,) uſed for thoſe handmaids of the ancient clergy, otherwiſe called *ſubintroductæ*.

ADORATION is particularly uſed for the act of praying, or preferring our requeſts or thankſgivings to Almighty God.

ADORATION is alſo uſed for certain extraordinary civil honours or reſpects which reſemble thoſe paid to the Deity, yet are given to men.

ADORATION is more particularly uſed for kiſſing one's hand in preſence of another, as a token of reverence. The Jews adored by kiſſing their hands and bowing down their heads; whence, in their language, *kiſſing* is properly uſed for *adoration*.

ADOS, ſignifies water in which red hot iron has been cooled.

ADOSCULATION, a term uſed by Dr. Grew, to imply a kind of impregnation, without intromiſſion; and in this manner he ſuppoſes the impregnation of plants is effected by the falling of the farina foecundans on the piſtil.

ADOSEE, in heraldry, ſignifies two figures or bearings being placed back to back.

ADOXA, TUBEROUS MOSCHATEL, HOLLOWROOT, or INGLORIOUS; a genus of the tetragynia order, belonging to the octandria claſs of plants. In the natural method it belongs to the 13th order, or ſucculentæ. The leaves and flowers ſmell like muſk, from whence it has by ſome been called muſk-crowfoot. For the genuine characters ſee the Syſtem of BOTANY.

AD PONDUS OMNIUM, among phyſicians, an abbreviation in their preſcriptions, ſignifying that the laſt mentioned ingredient is to weigh as much as all the reſt together.

AD QUOD DAMNUM, in law, a writ directed to the ſheriff, commanding him to inquire into the damage which may befal from granting certain privileges to a plaee, as a fair, a market, or the like.

ADRACHNE, in botany, a ſpecies of the ſtrawberry-tree.

ADRASTEA, in antiquity, an epithet given to the goddeſs Nemeſis, or Revenge. It was taken from king Adraſtus, who firſt erected a temple to that deity.

ADRASTIA *Certamina*, in antiquity, a kind of Pythian games, inſtituted by Adraſtus king of Argos, in the year of the world 2700, in honour of Apollo, at Sicyon. Theſe are to be diſtinguiſhed from the Pythian games at Delphi.

ADRIANISTS, in eccleſiaſtical hiſtory, a ſect of heretics divided into two branches; the firſt were diſciples of Simon Magus, and flouriſhed about the year 34. Theodoret is the only perſon who has preſerved the name and memory; but he gives us no account of their origin. Probably this ſect, and the ſix others which ſprung from the Simonians, took their name from the particular diſciples of Simon. The ſecond were the followers of Adrian Hamſtead, the anabaptiſt; and held ſome particular tenets.

ADRIFT, the ſtate of a ſhip broke looſe from her moorings, and driven without controul at the mercy of the wind, ſeas, or current, or of all of them together.

ADRIUNE, in botany, the cyclamen, or ſow bread.

ADROGATION, in Roman antiquities, a ſpecies of adoption, whereby a perſon who was capable of chooſing for himſelf was admitted by another into the relation of a ſon. The word is compounded of *ad*, to, and *rogare*, to aſk, on account of a queſtion put in the ceremony of it, Whether the adopter would take ſuch a perſon for his ſon? and another to the adoptive, Whether he conſented to become ſuch a perſon's ſon?

ADROP, in alchemy, the philoſopher's ſtone.

ADSCRIPTS, in mathematics, natural tangents.

ADSIDELLA, in antiquity, the table at which the flamens ſat during the ſacrifices.

ADSTRICTION, among phyſicians, a term uſed to denote the rigidity of any part.

ADVANCE, in the mercantile ſtyle, denotes money paid before goods are delivered, work done, or buſineſs performed.

ADVANCED, in a general ſenſe, denotes ſomething poſted or ſituated before another. Thus,

ADVANCED *Ditch*, in fortification, is that which ſurrounds the glacis or eſplanade of a place.

ADVANCED *Guard*, or *Vanguard*, in the art of war, the firſt line or diviſion of an army, ranged or marching in order of battle; or, it is that part which is next the enemy, and marches firſt towards them.

ADNANCED *Guard* is more particularly uſed for a ſmall party of horſe ſtationed before the main guard.

ADVANCER, among ſportſmen, one of the ſtarts or branches of a buck's attire, between the back antler and the palm.

ADUAR, in the Arabian and Mooriſh cuſtoms, a kind of ambulatory village, conſiſting of tents, which theſe people remove from one place to another, as ſuits their conveniency.

ADVENT, in the calendar, properly ſignifies the approach of the feaſt of the nativity. It includes four Sundays, which begin on St. Andrew's day, or on the Sunday before or after it. During advent, and to the end of the octaves of epiphany, the ſolemnizing of marriage is forbid without a ſpecial licence. It is appointed to employ the thoughts of Chriſtians on the firſt advent or coming of Chriſt in the fleſh, and his ſecond advent or coming to judge the world. The primitive Chriſtians practiſed great auſterity during this ſeaſon.

ADVENTITIA *Canæ*, in antiquity, a welcome-home feaſt, in honour of a perſon returned from a long journey; uſually prepared by his friends.

ADVENTITIOUS, what caſually accrues from without, i. e. not belonging to the body to which it is ſubjoined.

ADVENTITIOUS, in civil law, implies caſual legacies.

ADVENTITIOUS, in eutomology, ſhells that cannot be claſſed.

ADVENTURE, in a general ſenſe, implies ſome extraordinary or accidental event. It alſo denotes a hazardous or difficult undertaking.

Bill of ADVENTURE, among merchants, a writing ſigned by a merchant, teſtifying the goods mentioned in it to be ſhipped on board a certain veſſel belonging to another perſon, who is to run all hazards; the merchant only obliging himſelf to account to him for the produce.

ADVENTURER, in a general ſenſe, denotes one who hazards ſomething.

ADVENTURERS, is particularly uſed for an ancient company of merchants and traders, eſtabliſhed for the diſcovery of lands, territories, trades, &c. unknown. The ſociety of adventurers had its riſe in Burgundy, and its firſt eſtabliſhment from John Duke of Brabant in 1248; being known by the name of The Brotherhood of St. Thomas à Becket. It was afterwards tranſlated into England, and ſucceſſively confirmed by Edward III. and IV. Richard III. Henry IV. V. VI. and VII. who gave it the appellation of Merchant Adventurers.

ADVERB, in grammar, a particle joined to a verb, adjective, or participle, to explain their manner of acting or ſuffering; or to mark ſome circumſtance or quality ſignified by them. The word is formed from the prepoſition *ad*, to, and *verbum*, a verb; and ſignifies literally a word joined to a verb, to ſhew how, when, or where, one is, does, or ſuffers; as, the boy paints *neatly*; writes *ill*; the houſe ſtands *there*, &c. See GRAMMAR.

ADVERSARIA, among the ancients, a book of accounts, not unlike our journals or day-books.

ADVERSATIVE, in grammar, a word expreſſing ſome difference between what goes before and what follows it. Thus, in the phraſe, "He is an honeſt man, but a great enthuſiaſt," the word *but* is an adverſative conjunction.

ADVERSATOR, in antiquity, a ſervant who attended the rich in returning from ſupper, to give them notice of any obſtacles in the way, at which they might be apt to ſtumble.

ADVERTISEMENT, in a general ſenſe, denotes any information given to perſons intereſted in an affair; and is more particularly uſed for a brief account of an affair inſerted in the public papers, for the information of all concerned.

ADULT, an appellation given to any thing that is arrived at maturity: thus we ſay, an adult perſon, an adult plant, &c.

ADULTERATION, the act of debaſing, by an improper mixture, ſomething that was pure and genuine.

ADULTERATION *of Coin*, properly imports the making or caſting of a wrong metal, or with too baſe or too much alloy.

Adulterations of coins are effected divers ways; as, by forging another ſtamp or inſcription; by mixing impure metals with the gold or ſilver: moſt properly, by making uſe of a wrong metal, or an undue alloy, or too great an admixture of the baſer metals with gold or ſilver. Counterfeiting the ſtamp, or clipping and leſſening the weight, do not ſo properly come under the denomination of adulterating. Adulterating is ſomewhat leſs extenſive than debaſing, which includes diminiſhing, clipping, &c.

To adulterate or debaſe the current coin, is a capital crime in all nations.

ADULTERER, a man who commits adultery.

ADULTERESS, a woman guilty of adultery. An adultereſs, by our law, undergoes no temporal puniſhment whatever, except the loſs of her dower; and ſhe does not loſe even that, if her huſband is weak enough to be reconciled to her, and cohabit with her after the offence committed. 13 Ed. I. cap. 34.

But it is to be obſerved, that adultereſſes are ſuch either by the canon or civil law. According to the former, a woman is an adultereſs who, either being herſelf married, converſes carnally with another man; or being ſingle herſelf, converſes with a man that is married. According to the latter, ſhe is not an adultereſs, if ſhe be not herſelf in the married ſtate, though ſhe converſes with a man that is. The crime, in this caſe, was more properly called *ſtuprum* than *adulterium*. Hence, among the Romans, the word *adultera*, adultereſs, differed from *pellex*, which denoted a ſingle woman who cohabited with a married man: and *pellex* differed from *concubina*, which ſignified her who had only intercourſe with an unmarried man. The former was reputed infamous, and the latter innocent.

ADULTERINE, in the civil law, is particularly applied to a child iſſued from an adulterous amour or commerce.

ADULTERY, an unlawful commerce between one married perſon and another, or between a married and unmarried perſon.

Puniſhments have been annexed to adultery in moſt ages and nations, though of different degrees of ſeverity. In many it has been capital; in others venial, and attended only with ſlight pecuniary mulcts. Some of the penalties are ſerious, and even cruel; others of a jocoſe and humorous kind. Even contrary things have been enacted as puniſhments for adultery. By ſome laws the criminals are forbid marrying together, in caſe they became ſingle; by others, they are forbid to marry any beſides each other; by ſome, they are incapacitated from ever committing the like crime again; by others, they are glutted with it till it becomes downright nauſeous.

Among the rich Greeks, adulterers were allowed to redeem themſelves by a pecuniary fine; the woman's father, in ſuch caſes, returned the dower he had received from her huſband, which ſome think was refunded by the adulterer. Another puniſhment among thoſe people was, putting out the eyes of adulterers.

By the Jewiſh law, adultery was puniſhed by death in both parties, where they were both married, or only the woman. The Jews had a particular method of trying, or rather purging an adultereſs, or a woman ſuſpected of the crime, by making her drink the bitter waters of jealouſy; which, if ſhe were guilty, made her ſwell.

In Spain, they puniſhed adultery in men by cutting off that part which had been the inſtrument of the crime. In Poland, before Chriſtianity was eſtabliſhed, they puniſhed adultery and fornication in a very particular manner: the criminal they carried to the market-place, and there faſtened him by the teſticles with a nail; laying a razor within his reach, and leaving him under a neceſſity, either of doing juſtice upon himſelf, or of periſhing in that condition.

The Saxons formerly burnt the adultreſs, and over her aſhes erected a gibbet, whereon the adulterer was hanged. In this kingdom, likewiſe, adultery, by the ancient laws, was ſeverely puniſhed. King Edmund the Saxon ordered adultery to be puniſhed in the ſame manner as homicide; and Canute the Dane ordered that a man who committed adultery ſhould be baniſhed, and that the woman ſhould have her noſe and ears cut off. In the time of Henry I. it was puniſhed with the loſs of eyes and genitals.

In Britain, adultery is reckoned a ſpiritual offence, that is, cognizable by the ſpiritual courts, where it is puniſhed by fine and penance. The common lawt akes no farther notice of it, than to allow the party grieved an action and damages.

Adultery is ſometimes uſed, in a more extenſive ſenſe, for any ſpecies of impurity or crime, againſt the virtue of chaſtity.

ADVOCATE, among the Romans, a perſon ſkilled in their law, who undertook the defence of cauſes at the bar. The Roman advocates anſwered to one part of the office of a barriſter in England, viz. the pleading part; for they never gave counſel, that being the buſineſs of the *juriſconſulti*.

Advocate is ſtill uſed in countries and courts where the civil law obtains, for thoſe who plead and defend the cauſes of clients truſted to them.

Advocate is more particularly uſed, in church hiſtory, for a perſon appointed to defend the rights and revenues of a church or religious houſe.

Conſiſtorial Advocates; officers of the conſiſtory at Rome, who plead in all oppoſitions to the diſpoſal of benefices in that court: they are ten in number.

Elective Advocates, thoſe choſen by the abbot, biſhop, or chapter; a particular licence being had from the king, or prince, for that purpoſe. The elections were originally made in the preſence of the count of the province.

Fiſcal Advocate, *fiſci advocatus*, in Roman antiquity, an officer of ſtate under the Roman emperors, who pleaded in all cauſes wherein the *fiſcus*, or private treaſury, was concerned.

Matricular Advocates were the advocates of the mother or cathedral churches.

Military Advocates, thoſe appointed for the defence of the church, rather by arms and authority than by pleading and eloquence. Theſe were introduced in the times of confuſion, when every perſon was obliged to maintain their own property by force: biſhops and abbots not being permitted to bear arms, and the ſcholaſtic or gowned advocates being equally unacquainted with them, recourſe was had to knights, noblemen, ſoldiers, or even to princes.

Nominative Advocates, thoſe appointed by a king or pope. Sometimes the churches petitioned kings, &c. to appoint them an advocate; at other times this was done of their own accord. By ſome regulations, no perſon was capable of being elected advocate, unleſs he had an eſtate in land in the ſame county.

Subordinate Advocates, thoſe appointed by other ſuperior ones, acting under them, and accountable to them. There were various reaſons for the creation of theſe ſubordinate advocates; as, the ſuperior quality of the principal advocate, his being detained in war, or being involved in other affairs; but chiefly the too great diſtance of ſome of the church-lands, and their lying in the dominions of foreign princes.

Supreme or *Sovereign* Advocates, were thoſe who had the authority in chief; but acted by deputies or ſubordinate advocates. Theſe were called alſo *principal*, *greater*, and ſometimes *general* advocates. Such in many caſes were kings, &c. when either they had been choſen advocates, or became ſuch by being founders or endowers of churches. Princes had alſo another title to advocateſhip, ſome of them pretending to be *advocati nati* of the churches within their dominions.

Advocate, in the Engliſh courts, are more generally called *counſel*.

ADVOWEE, in law, implies the patron of a church, or the perſon who has a right to preſent a benefice.

ADVOWSON, or Advowzen, in common law, ſignifies a right to preſent to a vacant benefice. Advowſon is ſo called, becauſe the right of preſenting to the church was firſt gained by ſuch as were founders, benefactors, or maintainers of the church.

Though the nomination of fit perſons to officiate in every dioceſe was originally in the biſhop, yet they were content to let the founders of churches have the nomination of the perſons to the churches ſo founded, reſerving to themſelves a right to judge of the fitneſs of the perſons ſo nominated.

Advowſons formerly were moſt of them appendant to manors, and the patrons were parochial barons: the lordſhip of the manor and patronage of the church were ſeldom in different hands, until advowſons were given to religious houſes. But of late times the lordſhip of the manor and advowſon of the church have been divided.

Advowſons are *preſentative*, *collative*, or *donative*: *preſentative*, where the patron preſents or offers his clerk to the biſhop of the dioceſe, to be inſtituted in his church; *collative*, where the benefice is given by the biſhop, as original patron thereof, or by means of a right he has acquired by lapſe; *donative*, as where the king or other patron does, by a ſingle donation in writing, put the clerk into poſſeſſion, without preſentation, inſtitution, or induction.

ADUST, Adustus, among phyſicians, &c. is applied to ſuch humours as by long heat become of a hot and fiery nature. Such is cholar ſuppoſed to be. Melancholy is uſually conſidered as black and aduſt bile. Blood is ſaid to be aduſt, when, by reaſon of ſome extraordinary heat, its more ſubtile parts are all evaporated, leaving the groſſer, with all the impurities therein, half torrified.

ADY, in natural hiſtory, a name given to the palm-tree of the iſland of St. Thomas.

ADYNAMIA, in medicine, debility, or weakneſs, from ſickneſs.

ADYNAMON, among ancient phyſicians, a kind of weak factitious wine, prepared from muſt boiled down with water; to be given to patients to whom genuine wine might be hurtful.

ADYTUM, in Pagan antiquity, the moſt retired and ſacred place of their temples, into which none but the prieſts were allowed to enter.

ADZE, or Addice, a cutting tool of the ax kind; having its blade made thin and arching, and its edge at right angles to the handle; chiefly uſed for taking off thin chips of timber or boards, and for paring away certain irregularities which the ax cannot come at.

ÆACEA, in Grecian antiquity, ſolemn feſtivals and games celebrated at Ægina, in honour of Æacus.

ÆCHMALOTARCHA, in Jewiſh antiquity, a title given to the principal leader or governor of the Hebrew captives reſiding in Chaldea, Aſſyria, and the neighbouring countries.

The Jewiſh writers aſſure us, that the *æchmalotarchæ* were only to be choſen out of the tribe of Judah. The eaſtern Jews had their princes of the captivity, as the weſtern Jews their patriarchs. The Jews are ſtill ſaid to have an *æchmalotarcha* at Babylon, but without the authority of the ancient ones.

ÆDES, in Roman antiquity, beſides its more ordinary ſignification of a houſe, likewiſe ſignified an inferior kind of temple, conſecrated to ſome deity.

ÆDILE, *Ædilis*, in Roman antiquity, a magiſtrate whoſe chief buſineſs was to ſuperintend buildings of all kinds, but more eſpecially public ones, as temples, aqueducts, bridges, &c.

ÆDILITIUM Edictum, among the Romans, was that whereby a remedy was given a buyer, in caſe a vicious or unſound beaſt, or ſlave, was ſold him. It was called *ædilitium*, becauſe the preventing of frauds in ſales and contracts belonged eſpecially to the curule ædiles.

ÆDITUUS, in Roman antiquity, an officer belonging to the temple, who had the charge of the offerings, treaſure, and ſacred utenſils. The female deities had a woman officer of this kind called *Æditua*.

ÆGAGROPILA, a ball compoſed of a ſubſtance reſembling hair, generated in the ſtomach of the chamois-goat. This ball is of the ſame nature with thoſe found in cows, hogs, &c.

ÆGIAS, among phyſicians, a white ſpeck on the pupil of the eye, which occaſions a dimneſs of ſight.

ÆGILOPS, the name of a tumor in the great angle of the eye; either with, or without, an inflammation. The tumor, before it becomes ulcerous, is properly called *anchilops*; and, after it is got into the lachrymal paſſages, and has rendered the os lachrymale carious, *fiſtula lachrymalis*.

If the ægilops be accompanied with an inflammation, it is ſuppoſed to take its riſe from the abundance of blood which a plethoric habit diſcharges on the corner of the eye. If it be without an inflammation, it is ſuppoſed to proceed from a viſcous pituitous humour thrown upon this part.

The method of cure is the ſame as that of the ophthalmia. But before it has reached the lachrymal paſſages, it is managed like other ulcers. If the ægilops be neglected, it burſts, and degenerates into a fiſtula, which eats into the bone.

Ægilops, Wild Feſtuc; a genus of the monœcia order, belonging to the polygamia claſs of plants, and ranking under the 4th natural order, Gramina.—For the generic characters, ſee Syſtem of Botany.

ÆGILOPS is alſo the trivial name of a ſpecies of QUERCUS.

ÆGINETA, in Botany, the name given by Linnæus to a genus in plants belonging to the claſs of *didynamia angioſpermia*.

ÆGIPAN, in heathen mythology, a denomination given to the god Pan, becauſe he was repreſented with the horns, legs, feet, &c. of a goat.

ÆGIPHILA, GOAT-FRIEND; a genus of the monogynia order, belonging to the tetandria claſs of plants.—For the Generic characters, ſee Syſtem of BOTANY. There is only one ſpecies, a native of Martinico.

ÆGOBOLIUM, in antiquity, the ſacrifice of a goat offered to Cybele.

ÆGOPODIUM, SMALL WILD ANGELICA, GOUTWORT, GOATSFOOT, HERB GERARD, or ASHWEED; a genus of the digynia order, belonging to the pentandria claſs of plants.—For the Generic characters, ſee Syſtem of BOTANY. There is but one ſpecies, a native of Britain and other parts of Europe. It is very common under hedges and about gardens: the leaves reſemble thoſe of Angelica, and it carries ſmall white flowers. Its roots run ſo faſt as to render it a very troubleſome weed.

ÆGOPRICON, a genus of the monœcia order, belonging to the diandria claſs of plants.—For the Generic characters, ſee Syſtem of BOTANY. There is but one ſpecies, a native of Surinam.

ÆGYPTIACUM, in pharmacy, the name of ſeveral detergent ointments.

ÆINATÆ, in antiquity, a denomination given to the ſenators of Miletus, becauſe they held their deliberations on board a ſhip, and never returned to land till matters had been agreed on.

AEM, AM, or AME, a liquid meaſure uſed in moſt parts of Germany; but different in different towns. The aem commonly contains 20 vertils, or 80 maſſes; that of Heidelbergh is equal to 48 maſſes; and that of Wirtembergh 160 maſſes.

ÆMOBOLIUM, in antiquity, the blood of a bull, or ram, offered in the ſacrifices, called *taurobolia* and *criobolia*; in which ſenſe the word occurs in antient inſcriptions.

ÆNEATORES, in antiquity, the muſicians in an army, including thoſe who played trumpets, horns, &c. The word is formed from *æneus*, on account of the brazen inſtruments uſed by them.

ÆNEID, the name of Virgil's celebrated epic poem. The ſubject of the Æneid is the eſtabliſhment of Æneas in Italy. Nothing could be more intereſting to the Romans than to look back to their origin from ſo famous a hero. While the object was ſplendid itſelf, the traditionary hiſtory of his country opened intereſting fields to the poet; and he could glance at all the future great exploits of the Romans, in its antient and fabulous ſtate. Therefore the ſtory is extremely happy, inaſmuch as every particular that can enhance the value of unity, action, and probability, are combined to give this elegant poem due weight and conſequence; and indeed ſurpaſſes almoſt every compoſition in the Roman language.

ÆNIGMA denotes any dark ſaying, wherein ſome well-known thing is concealed under obſcure language.

Painted ÆNIGMAS are repreſentations of the works of nature, or art, concealed under human figures, drawn from hiſtory or fable.

The Form of ÆNIGMAS conſiſts in the words, which, whether they be in proſe or verſe, contain either ſome deſcription, a queſtion, or a proſopopæia. The laſt kind are the moſt pleaſing, inaſmuch as they give life and action to things which otherwiſe have them not.

The Explication of ÆNIGMAS makes a conſiderable exerciſe; and that one of the moſt difficult and amuſing, where wit and penetration have the largeſt field. By explaining an ænigma is meant the finding a motto correſponding to the action and perſons repreſented in a picture, taken either from hiſtory or mythology. The great art of this exerciſe conſiſts in the choice of a motto, which either by itſelf, or the circumſtances of time, place, perſon who ſpeaks, or thoſe before whom he is ſpeaking, may divert the ſpectators, and furniſh occaſion for ſtrokes of wit; alſo in ſhowing to advantage the conformities between the figure and the thing figured, giving ingenious turns to the reaſons employed to ſupport what is advanced, and in artfully introducing pieces of poetry to illuſtrate the ſubject and awaken the attention of the audience.

In antient hiſtory we meet with ſome ænigmas complicated to a degree, and which have greatly perplexed the interpreters of them. Such is that celebrated ancient one, *Ælia Lælia Criſpis*, of which we have two exemplars; one found 140 years ago on a marble near Bolognia; the other in an antient MS. written in Gothic letters at Milan. It is controverted between the two cities, which is to be reputed the more authentic.

The Bolognian Ænigma.

D. M.
Ælia Lælia Criſpis;
Nec vir, nec mulier,
Nec androgyna;
Nec puella, nec juvenis,
Nec anus;
Nec caſta, nec meretrix,
Nec pudica;
Sed omnia:
Sublata
Neque fame, neque ferro,
Neque veneno;
Sed omnibus:
Nec cœlo, nec terris,
Nec aquis,
Sed ubique jacet.
Lucius Agatho Priſcius,
Nec maritus, nec amator,
Nec neceſſarius;
Neque mærem, neque gaudens,
Neque flens;
Hanc,
Nec molem, nec pyramidem,
Nec ſepulchrum,
Sed omnia,
Scit et neſcit, cui poſuerit.

That is to ſay, "To the gods manes, Ælia Lælia Criſpis; neither man, nor woman, nor hermaphrodite; neither girl, nor young woman, nor old; neither chaſte, nor a whore; but all theſe: killed neither by hunger, nor ſteel, nor poiſon; but by all theſe: reſts neither in heaven, nor on earth, nor in the waters; but every where. Lucius Agatho Priſcius, neither her huſband, nor lover, nor friend; neither ſorrowful, nor joyful, nor weeping, certain, or uncertain, to whom he rears this monument, neither erects her a temple, nor a pyramid, nor a tomb, but all theſe." In the MS. at Milan, inſtead of D. M. we find A. M. P. P. D. and at the end the following addition:

Hoc eſt ſepulchrum intus cadaver non habens
Hoc eſt cadaver ſepulchrum extra non habens,
Sed cadaver idem eſt et ſepulchrum.

We find near 50 ſeveral ſolutions of this ænigma advanced by learned men. Marius Michael Angelus maintains Ælia Lælia Criſpis to ſignify rain-water falling into the ſea. Ri. Vitus firſt explained it of Niobe turned to a ſtone, afterwards of the rational ſoul, and afterwards of the Platonic idea; Jo. Turrius, of the *materia prima*; Fr. Schottus, of an eunuch; Nic. Bernardus, of the philoſopher's ſtone, in which he is followed by Borrichius; Zach. Pontinus, of three human bodies in the ſame ſituation, and buried by three different men at the ſame time; Neſmondius, of a law-ſuit; Jo. Gaſ. Gerartius, of love; Zu. Boxhornius, of a ſhadow; P. Terronius, of muſic; Fort Licetus, of generation, friendſhip. and privation: M. Ov. Montalbanus, of hemp; Car. Cæſ. Malvaſia, of an abortive girl promiſed in marriage; Pet. Mengulus, of the rule of chaſtity, preſcribed by the founder of the military religion of St. Mary; M. de Ciconia, of pope Joan; Heumannus, of Lot's wife; and laſtly, J. C. S. an anonymous writer in the Leipſic Acts, of the Chriſtian church.

ÆNICMATOGRAPHY, or ÆNIGMATHOLOGY, the art of reſolving or making ænigmas.

ÆNITHOLOGIUS, in poetry, a verſe of two dactyls and three trochæi.

ÆOLIC, in a general ſenſe, denotes ſomething belonging to Æolis.

ÆOLIC, or ÆOLIAN, in grammar, one of the five dialects, of the Greek tongne. It was firſt uſed in Bœotia; whence it paſſed in Æolia, and was that which Sappho and Alcæus wrote in. The Æolic dialect generally throws out the aſpirate or ſharp ſpirit, and agrees in ſo many things with the DORIC dialect that the two are uſually confounded together.

The *Æolic digama* is a name given to the letter F, which the Æolians uſed to prefix to words beginning vowels, as Ζοινος for οινος; alſo to inſert between vowels, as οΖις for οις.

ÆOLIC *Verſe*, in proſody, a verſe conſiſting of an iambus, or ſpondee; then of two anapeſts, ſeparated by a long ſyllable; and, laſtly, another ſyllable. Such as, *O ſtelliferi conditor orbis.* This is otherwiſe called *eulogic* verſe; and, from the chief poets who uſed it, *Archilochian* and *Pindaric*.

ÆOLIPILE, in hydraulics, is a hollow ball of metal, generally uſed in courſes of experimental philoſophy, in order to demonſtrate the poſſibility of converting water into an elaſtic ſteam or vapour by heat. The inſtrument, therefore, conſiſts of a ſlender neck, or pipe, having a narrow orifice inſerted into the ball by means of a ſhouldered ſcrew. This pipe being taken out, the ball is filled almoſt full of water, and the pipe being again ſcrewed in, the ball is placed on a pan of kindled charcoal, where it is well heated, and there iſſues from the orifice a vapour, with prodigious violence and great noiſe, which continues till all the included water is diſcharged. The ſtronger the fire is the more elaſtic and violent will be the ſteam; but care muſt be taken that the ſmall orifice of the pipe be not, by any accident, ſtopped up; becauſe the inſtrument would, in that caſe, infallibly burſt, and with ſuch violence as may greatly endanger the lives of the perſons near it. Another way of introducing the water is to heat the ball red hot when empty, which will drive out almoſt all the air; and then by ſuddenly immerging it in water, the preſſure of the atmoſphere will force in the fluid, till it is nearly full. Des Cartes and others have uſed this inſtrument to account for the natural cauſe and generation of the wind: and hence it was called Æolopila, q. d. *pila Æoli*, the ball of Æolus, or of the god of the winds.

ÆOLUS, in heathen mythology, the god of the winds, was ſaid to be the ſon of Jupiter by Acaſta, or Sigeſia, the daughter of Hipotus; or, according to others, the ſon of Hippotus by Meneclea, daughter of Hyllus king of Lipara.

ÆON, a Greek word, properly ſignifying the age or duration of any thing.

ÆON, among the followers of Plato, was uſed to ſignify any virtue, attribute, or perfection: hence they repreſented the deity as an aſſemblage of all poſſible æons; and called him *pleroma*, a Greek term ſignifying fullneſs. The Valentinians, who, in the firſt ages of the church, blended the conceits of the Jewiſh cabaliſts, the Platoniſts, and the Chaldean philoſophers, with the ſimplicity of the Chriſtian doctrine, invented a new kind of theogony, or genealogy of gods (not unlike that of Heſiod) whom they called by ſeveral glorious names, and all by the general appellation of ÆONS: among which they reckoned Ζωη, life; Δολος, word; Μονογενης, only-begotten; Πληρωμα, fullneſs; and many other divine powers and emanations, amounting in number to thirty: which they fancied to be ſucceſſively derived from one another; and all from one ſelf-originated deity, named *Bythus*, i. e. profound or unfathomable; whom they called likewiſe, The moſt high and ineffable Father.

ÆORA, among ancient writers on medicine, is uſed for geſtation; which ſort of exerciſe was often preſcribed by the phyſicians of thoſe days. Other exerciſes conſiſted principally in the motion of the body; but in the *æora* the limbs were at reſt, while the body was carried about and moved from place to place, in ſuch a manner as the phyſician preſcribed.

ÆRA, in chronology, a fixed point of time from whence any number of years is begun to be counted.

It is ſometimes alſo written in antient authors *Era*. The origin of the term is conteſted, though it is generally allowed to have had its riſe in Spain. Sepulveda ſuppoſes it formed from A. ER. A. the notæ or abbreviatures of the words, *annus erat Auguſti*, occaſioned by the Spaniards beginning their computation from the time their country came under the dominion of Auguſtus, or that of receiving the Roman calendar. This opinion, however ingenious, is rejected by Scaliger, not only on account that in the ancient abbreviatures *A* never ſtood for *annus*, unleſs when preceded by *V* for *vixit*; and that it ſeems improbable they ſhould put ER for *erat*, and the letter A, without any diſcrimination, both for *annus* and *Auguſtus*. Voſſius nevertheleſs favours the conjecture, and judges it at leaſt as probable, as either that of Iſidore, who derives *æra* from *æs*, the "tribute-money," wherewith Auguſtus taxed the world: or that of Scaliger himſelf, who deduces it likewiſe from *æs*; though in a different manner. *Æs*, he obſerves, was uſed among the ancients for an *article* or *item* in an account; and hence it came alſo to ſtand for a ſum or number itſelf. From the plural *æra*, came by corruption *æra*, *æram*, in the ſingular; much as *Oſtia*, *Oſtiam*, the name of a place, from *Oſtia*, the mouths of the Tyber.

The difference between the terms æra and epoch is, that the æras are certain points fixed by ſome people, or nation; and the epochs are points fixed by chronologiſts and hiſtorians. The idea of an æra comprehends alſo a certain ſucceſſion of years proceeding from a fixed point of time, and the epoch is that time itſelf. Thus the Chriſtian æra began at the epoch of the birth of Jeſus Chriſt.

ÆRA is alſo uſed by ſome writers of the barbarous ages to ſignify any year.

ÆRA ſignifies alſo cockle or darnel.

ÆRARIUM, the treaſury or place where the public money was depoſited amongſt the Romans.

ÆRARIUM *Sanctius* contained the monies ariſing from the twentieth part of all legacies: this was kept for the extreme neceſſities of the ſtate.

ÆRARIUM *Privatum* was the emperor's privy purſe, or the place where the money ariſing from his private patrimony was depoſited.

ÆRARIUM *Viceſimarum*, the place where the money ariſing from the taxes levied from foreign countries was laid up, ſo called becauſe it moſt commonly conſiſted of a twentieth part of the produce.

ÆRARIUM *Ilithyæ*, or *Junonis Luncinæ*, was where the monies were depoſited which parents paid for the birth of each child.

There are ſeveral other treaſuries mentioned in hiſtory, as the *ærarium Juventutis*, *Veneris*, &c. The temple of Saturn was the public treaſury of Rome, either becauſe Saturn firſt taught the Italians to coin money, or, which is moſt likely, becauſe this temple was the ſtrongeſt and moſt ſecure, and therefore the fitteſt place for that purpoſe.

ÆRARIUM differs from *fiſcus*, as the firſt contained the public money, the ſecond that of the prince. The two are, however, ſometimes indiſcriminately uſed for each other.

ÆRARIUS, a name given by the Romans to a degraded citizen, who had been ſtruck off the liſt of his century. Such perſons were ſo called becauſe they were liable to all the taxes (æra) without enjoying any of its privileges.

The *ærarii* were incapable of making a will, of inheriting, of voting in aſſemblies, of enjoying any poſt of honour or profit; in effect, were only ſubject to the burdens, without the benefits of ſociety; yet they retained their freedom, and were not reduced to the condition of ſlaves. To be made an *ærarii*, was a puniſhment inflicted for ſome offence, and reputed one degree more ſevere than to be expelled a tribe, *tribu moveri*.

ÆRARIUS was alſo an officer inſtituted by Alexander Severus, for the diſtribution of the money given in largeſſes to the ſoldiery or people.

ÆRARIUS was alſo uſed for a perſon employed in coining or working braſs.

Theſe are ſometimes called *ærarii fuſores*: at other times, *ærarius* is diſtinguiſhed from *fuſor*; the former anſwering to what we now call copper-ſmiths, the latter to founders.

ÆRATIUS was likewiſe applied to a ſoldier who received pay.

AERIAL, in a general ſenſe, denotes ſomething partaking of the nature of air.

AERIAL *Perſpective*. See Syſtem of PERSPECTIVE.

AERIANS, in church-hiſtory, a branch of Arians, who to the doctrines of that ſect, added ſome peculiar dogmas of their own; as, that there is no difference between biſhops and prieſts; a doctrine maintained by many modern divines, particularly of the preſbyterian and reformed churches. The ſect received its denomination from Aerius, an Armenian prieſt of the fourth century. He founded his doctrine chiefly upon ſome paſſages in St. Paul; and, among others, upon that in 1 Tim. iv. 14. where the apoſtle exhorts him not to neglect the gift he had received by *the laying on of the hands of the Preſbytery*. Here, obſerves Aerius, is no mention of biſhops: on the contrary, Timothy evidently received his ordination from the preſbyters or prieſts. Epiphanius zealouſly maintains the ſuperiority of biſhops againſt the Aerians. The word *preſbytery*, uſed by the apoſtle, he obſerves, includes both biſhops and prieſts; the whole ſenate or aſſembly of the eccleſiaſtics of the place.

Flos ÆRIS, among alchemiſts, ſignifies ſmall ſcales procured from copper melted by a ſtrong heat; it is ſometimes uſed for ærugo or verdigriſe.

AEROGRAPHY, from αηρ, air, and γραφω, I deſcribe; a deſcription of the air, or atmoſphere, its limits, dimenſions, properties, &c. This amounts to much the ſame with aerology, unleſs we ſuppoſe the latter to enter into the rational, and the former to confine itſelf to a deſcription of the more obvious affections thereof.

A NEW SYSTEM of AEROLOGY.

THIS Science includes all the phenomena, properties, ingredients, nature, ſpecies, and uſes of that inviſible fluid which ſurrounds this globe, called Air, on which depends the life of the kingdoms of nature.

DEFINITION I.

The ancients conſidered air to be an homogeneous fluid, the component parts of which were beyond the reach of man's wiſdom to diſcover. Its common operations were thought to be performed either by its heat or cold, its moiſture or dryneſs. And if any effects were diſcovered, which could not be explained by theſe, ſuch as the appearance of peſtilential diſeaſes, they were reckoned to be entirely ſupernatural, and the immediate effect of Divine Power. But however ſimple and homogeneous this fluid may have been thought in former times, it is ſo far from poſſeſſing the ſimplicity of an element, that it is the receptacle of all kinds of effluvia produced from terreſtrial ſubſtances, as well artificial as natural.

Hence, whatever may be the nature of the aërial fluid, when abſolutely pure, that which we breathe, and commonly goes under the name of air, muſt be conſidered as an exceedingly heterogeneous mixture, various at various times, and which it is by no means poſſible to analiſe with accuracy. Air ſeems to be a kind of maſs where all the poiſonous effluvia ariſing from putrid and corrupted matters are depoſited; yet it has a wonderful facility of purifying itſelf, and one way or other of depoſiting theſe vapours contained in it, ſo that it never becomes noxious, except at particular places, and for a ſhort time; the general maſs remaining upon all occaſions pretty much the ſame.

The way in which this purification is effected is different, according to the nature of the vapour with which the air is loaded. That which moſt univerſally prevails is water; and from experiment it appears, that the quantity of aqueous vapour contained in the atmoſphere is immenſe. Dr. Halley has proved, that the evaporation from the Mediterranean ſea is alone ſufficient to ſupply all the rivers that run into it with water.

Dr. Watſon, in his chemical eſſays, has demonſtrated, that where there had been no rain for the ſpace of a month, the evaporation from an acre of land, was no leſs than 1600 gallons of water in 24 hours. But in rainy weather he has proved, by ſeveral experiments, that the evaporation of liquids is not leſs than 3600 gallons per acre in the ſame time. Thus the air is every moment purified by the perpetual aſcent of theſe vapours.

Yet it is not entirely from the aqueous vapour that the air is purified at this time; for part of the effluvia ariſing from putrid and decayed ſubſtances of every kind, by attaching itſelf to the aqueous vapour, aſcends along with it. This phlogiſtic vapour, as the modern philoſophical text defines it, is alſo abſorbed by vegetables, as is proved by numerous experiments, and it may be aſſerted with great probability, that it is their proper food.

The phlogiſtic vapours which aſcend along with the water, probably continue there, and deſcend along with the rain; whence the fertilizing qualities of rain-water above thoſe of any other. Thus we may ſee why a dry air, whether cold or hot, muſt always be wholeſome; but as the atmoſphere cannot always receive vapours, it is obvious, that when great rains come on, eſpecially if attended with heat, the lower regions of the air muſt be overloaded with vapours both of the aqueous and phlogiſtic kind, and of conſequence be very unwholeſome.

But beſides the aqueous and phlogiſtic vapours, both of which are ſpecifically lighter than common air, there are others, which being ſpecifically heavier, cannot be carried off in this manner. Hence theſe groſs vapours contaminate certain places in the atmoſphere, rendering them not only unhealthy, but abſolutely poiſonous, viz.

1. Sulphureous, acid, and metalline exhalations, produced by volcanos, that deſcend in conſequence of their ſpecific gravity, and ſpread deſtruction all around them, poiſoning not only animals, but vegetables alſo.

2. The vapours ariſing from houſes where metals are ſmelted have the ſame pernicious qualities.

3. Emanations of fixed air, which ſometimes proceed from old lavas, ſo that the air ſeems not capable of purifying itſelf, otherwiſe than, either by diſperſing them by winds, or by letting them ſubſide by their ſuperior gravity, till they are abſorbed by the earth or water, according as it is their nature to unite with one or other of theſe elements. Hence, ſcarce any conſtitution of the atmoſphere can diſpel theſe noxious effluvia; nor does it ſeem probable that peſtilential diſtempers ever ceaſe, until the contagion has operated ſo long, and been ſo frequently communicated from one to another, that, like a ferment much expoſed to the atmoſphere, it becomes vapid, communicates a milder infection, and at laſt loſes its ſtrength altogether.

As the air is a ſolid body, it muſt need have gravity, or weight, which has been demonſtrated by experiment. For a bottle that holds a wine quart filled with air, weighs 16 grains heavier than when empty: and as a wine quart of water 14,621 grains, it is evident by this analogy, that common air is to water in its gravitation, as 1 is to 914 exactly.

By means of its gravity, the air preſſes with great force upon all bodies according to the extent of their ſurface; which I compute at 15 lb. on every ſquare inch.

According to ſome experiments made by M. Amontons and de la Hire, a column of air on the ſurface of the earth, and 36 fathoms high, is equal in weight to three lines depth of mercury. By the barometer the preſſure of the atmoſphere appears to be very different; ſometimes being only equal to a column of 28, and varying from thence to 31 inches. The whole quantity of preſſure muſt thus be immenſe, and has been computed equal to a globe of lead of 60 miles in diameter.

The gravity of the atmoſphere accompliſhes many uſeful purpoſes in nature. It prevents the arterial veſſels of animals and the ſap-veſſels of plants, from being too much diſtended by the expanſive power, which has a perpetual tendency to ſwell them out: as in the operation of cupping, where the preſſure of the air is taken off from a particular part, the expanſive force inſtantly acts, and ſwells out the veſſels to a great degree. Hence when animals are put into an air pump, their whole bodies ſwell.

By the gravity of the air the union of fluid bodies is promoted, which would otherwiſe inſtantly ceaſe in vacuo. For oils and ſalts, which remain united in air, ſeparate as ſoon as that fluid is extracted. Hence alſo when hot water is put under an exhauſted receiver, it boils violently, becauſe the preſſure of the air being now taken off, the particles of ſteam, which exiſted inviſibly in the water, and which the gravity of the atmoſphere prevented from flying off ſo ſoon, are now hurried up with great velocity by means of the exceſſive comparative gravity of the aqueous fluid. For on the gravity of the air depends the aſcent of water in pumps, ſyphons, &c. and likewiſe all the phenomena of the barometer. But it differs from all other fluids, as it can be compreſſed into a much leſs ſpace than what it naturally poſſeſſed. Nor can it be congealed like other fluids. However, it is to be remarked, that it is of a different denſity in every part upward from the earth's ſurface, decreaſing in its weight the higher it riſes, and therefore muſt alſo decreaſe in denſity.

The air is of an elaſtic ſpringy nature, and the force of its ſpring is equal to its weight. The elaſticity of the air was firſt aſcertained by ſome experiments of lord Bacon, who, upon this principle, conſtructed the firſt thermometor, which he called his vitrum calendare. Of this power we have numerous proofs. Thus, a blown bladdar being ſqueezed in the hand, we find the included air ſenſibly reſiſt; ſo that upon ceaſing to compreſs, the cavities or impreſſions made in its ſurface are readily expanded again and filled up.

The ſtructure and office of the air pump depend on this elaſtic property. Every particle of air always exerts an endeavour to expand, and thus ſtrives againſt an equal endeavour of the ambient particles; whoſe reſiſtance happening by any means to be weakened, it immediately diffuſes itſelf into an immenſe extent. Hence it is that thin glaſs bubbles, or bladders filled with air, and exactly cloſed, being included in the exhauſted receiver of an air pump, burſt by the force of the air they contain; and a bladder nearly flaccid ſwells in the receiver, and appears full. The ſame effect alſo takes place, though in a ſmaller degree, on carrying the flaccid bladder to the top of an high mountain.

It has been queſtioned among philoſophers, whether this elaſtic power of the air is capable of being deſtroyed or diminiſhed; but by ſeveral experiments I am ſatisfied it cannot.

The weight or preſſure of the air has no dependence on its elaſticity; but would be the ſame whether it had ſuch a property or not. In effect, the law of this elaſticity is, that it increaſes as the denſity of the air increaſes; and the denſity increaſes as the force increaſes by which it is preſſed. Now there muſt neceſſarily be a ballance between the action and re-action; i. e. the gravity of the air which tends to compreſs it, and the elaſticity by which it endeavours to expand, muſt be equal. Hence the elaſticity increaſing, or diminiſhing univerſally as the denſity increaſes or diminiſhes, it is no matter whether the air be compreſſed and retained in ſuch a ſpace by the weight of the atmoſphere, or by any other means; it muſt endeavour, in either caſe, to expand with the ſame force; conſequently if air near the earth be pent up in a veſſel, and all communication with the external fluid cut off, the preſſure of the incloſed air will be equal to the weight of the atmoſphere at the time the quantity was confined.

No ſtandard can be ſettled relative to the limitation of the denſity, compreſſion, rarefaction, or dilutation of the air. Therefore I omit the uſeleſs theorics of ſeveral authors on its principles and properties; as I ſhall not obtrude any thing I cannot aſſert as a fact, and for which proofs can be given.

The elaſtic power of this fluid inſinuates into the pores of bodies, thereby putting the particles of ſuch bodies into perpetual oſcillations; for the degree of heat, and the air's gravity and denſity, and conſequently its elaſticity and expanſion, never remaining the ſame for the leaſt ſpace of time, there muſt be an inceſſant vibration or dilatation and contraction in all bodies.

We obſerve this reciprocation in ſeveral inſtances, particularly in plants, the air veſſels of which do the office of lungs; for the contained air alternately expanding and contracting, according to the increaſe or diminution of the heat, alternately preſſes the veſſels and eaſes them again, thus keeping up a perpetual motion in their juices.

Hence we find, that no vegetation or germination will proceed in vacuo. The air is very inſtrumental in the production and growth of vegetables, not only by invigorating their ſeveral juices while in an elaſtic active ſtate, but alſo by greatly contributing in a fixed ſtate to the union and firm connections of their ſeveral conſtituent parts.

From the ſame cauſe it is that the air contained in the bubbles of ice, by its continual action burſts the ice. Thus alſo entire columns of marble ſometimes cleave in the winter time, from the increaſed elaſticity of ſome little bubble of air contained in them. From the ſame principle ariſe all putrefaction and fermentation, neither of which will proceed even in the beſt diſpoſed ſubjects in vacuo.

Since we find ſuch great quantities of elaſtic air generated in the ſolution of animal and vegetable ſubſtances, a good deal muſt conſtantly ariſe from the diſſolution of theſe aliments in the ſtomach and bowels, which is much promoted by it; and, in reality, all natural corruption and alteration ſeem to depend on the air.

This fluid acts not only by its common properties of gravity and elaſticity, but produces numerous other effects ariſing from the peculiar ingredients of which it conſiſts.

Thus, It not only diſſolves and attenuates bodies by its preſſure and attrition, but as a chaos containing all kinds of menſtrua, and conſequently poſſeſſing powers for diſſolving all bodies. It is known that iron and copper readily diſſolve and become ruſty in air, unleſs well defended with oil. Stones alſo undergo the changes incident to metals. Air has a conſiderable operation upon vitriol, even when a ſtrong fire could act no farther upon it. It has been proved by experiment, that the fumes of a corroſive liquor work more ſuddenly and manifeſtly on metal when ſuſtained in the air, than the menſtruum itſelf did, which emitted fumes on thoſe parts of the metal which it covered; referring to the effects of the effluvia of vinegar on copper.

The diſſolving power of air is increaſed by heat, and by other cauſes. It combines with water, and by acceſs of cold depoſits part of the matter which was kept diſſolved in it by a greater degree of heat. Hence the water, by being depoſited and condenſed upon any cold body, ſuch as glaſs, &c. in windows, forms fogs, and becomes viſible.

In chemical operations air is a very neceſſary and important agent; the reſult of particular proceſſes depending on its preſence or abſence, on its being open or incloſed. Thus, the parts of vegetables or animals can only be calcined in open air; in cloſe veſſels they never become any other than black coals. And theſe operations are effected by the changes to which the air is liable.

The changes in the air ariſe from various cauſes, and are obſervable not only in its mechanical properties, ſuch as gravity, denſity, &c. but in the ingredients that compoſe it.

The effluvia of animals, minerals and vegetables have their effect in varying the air: as is evident in contagious diſeaſes, murrains, plagues, and other mortalities, which are ſpread by an infected air.

From what has been obſerved it is evident, that the aerial fluid agitates bodies when in motion; reſiſts the motions made in it; ſuſtains bodies floating in it; and only differs in its general properties from the groſſer fluids; great rarity, elaſticity and tranſparency, being its diſtinguiſhing characters. The whole maſs of this fluid, with its contents, is called the atmoſphere; a term made uſe of when the effects that ariſe from its form, magnitude, denſity, rarefaction or dilatation are conſidered: but when the fluid of which the maſs is compoſed is indefinitely ſpoken of, with a view to develope its qualities, and conſider it independent of the bodies immerſed in, or mixed with it, it is called the air or aer.

This fluid is compoſed of an innumerable multitudeo f ſmall particles, generally defined atoms, alluding to their inviſible ſtate to the naked eye, or even to almoſt all magnifying glaſſes. And as thoſe particles are not in contact, they repel each other with a force that may be diminiſhed, but cannot be deſtroyed, by any degree of cold known in the vicinity of the earth. For if the particles were in contact the fluid could not be compreſſed; and if they did not repel each other, the fluid could not expand when the compreſſing force is removed. This property of the air has been proved by various methods; and as it is the received opinion of the philoſophers of the age, I think it neceſſary to add, the methods made uſe of for ſuch ſatisfaction: however, they ſhall be enumerated in their proper order.

The firſt object of enquiry that will follow from what has been already advanced, is the extent of the atmoſphere, i. e. its magnitude. In anſwer to which, it is only neceſſary to obſerve, that it is not only extended over the face of the earth, but that of the ſea likewiſe; as is evident from the ſuſpenſion and motion of the clouds; which proves alſo that its altitude is conſiderable; but the meaſure of this altitude muſt be obtained from its effects. If the ſpecific gravity of the air be found, and alſo its whole preſſure on bodies, it will be eaſy to diſcover the quantity of the fluid and its height, if ſuppoſed to be uniformly denſe. Or it may be deduced from optical conſiderations, by obſerving the effect it has on the light of the ſun.

We ſhall now proceed in order to aſcertain, agreeable to the lateſt diſcoveries, the ſeveral kinds of aerial fluid; a curious intereſting ſubject, in which every claſs of readers will find amuſement as well as uſeful knowledge.

DEFINITION II.

Dephlogiſticated Air poſſeſſes ſome of the properties of common air in a very eminent degree, but is deficient in others. Thoſe in which it excels are the ſupport of flame and of animal life. It is rather more elaſtic than common air; as it likewiſe exceeds it a little in ſpecific gravity, the proportion betwixt it and common air being that of 160 to 152. On introducing a lighted candle into dephlogiſticated air, the flame not only grows larger, but becomes exceedingly bright; and when the air is very pure, the candle burns with a crackling noiſe, as if the air contained ſome combuſtible matter, at the ſame time that the wax or tallow waſtes ſurpriſingly faſt.

The heat of the flame is in proportion to its light. If we fill a bladder with dephlogiſticated air, and then faſten to its neck a glaſs tube, whoſe aperture is drawn to a fine point, the dephlogiſticated air, if driven out by preſſing the bladder, will augment the heat of a candle to ſuch a degree, that if any ſmall bits of metal, placed on a piece of charcoal, be held in the apex of the flame, they will almoſt inſtantly be melted. Even grains of platina may by this means be melted; and in a larger fire there is no doubt that the effects of burning mirrors might be equalled.

On mixing dephlogiſticated and inflammable air together, an exploſion takes place as on mixing common and inflammable air, but with much greater violence. If an ounce vial, which for this purpoſe ſhould be very ſtrong, be filled with a little more than one-third of dephlogiſticated, and the reſt inflammable air, and the flame of a candle preſented to its mouth, it will explode nearly as loud as a ſmall piſtol.

It has been, almoſt throughout all ages, believed, that combuſtion in every inſtance diminiſhed common air, or reduced it to a ſmaller volume: but the late experiments of Mr. Lavoiſier have ſhown, that this is a miſtake; and that in ordinary proceſſes attended with the production of fixed and phlogiſticated air, the quantity of vapour produced is equivalent to that abſorbed, or otherwiſe made to diſappear during the operation. With dephlogiſticated air the caſe is very different, as it ſuffers by diminution.

The purity of dephlogiſticated air is aſcertained by its degree of diminution with nitrous air; which, like that of the diminution by liver of ſulphur, or otherwiſe, is to be conſidered as a phlogiſtic proceſs, or kind of burning, eſpecially as a conſiderable degree of heat is thereby generated. Very great differences are perceived in this reſpect; and according to the quantity of diminution, the air is ſaid to be two, three, or four times better than common air. It is not yet accurately determined how far this proportionable purity extends.

Dephlogiſticated air is much inferior to that of the common atmoſphere in ſupporting vegetable life. This has been aſcertained by the experiments of Dr. Prieſtley, and others, as herein after mentioned.

Dephlogiſticated air is one of the conſtituent and elementary parts of water, inflammable air being the other; though the opinion is ſtill conteſted by ſome foreign chemiſts. See Phil. Tranſ. Vol. 74, No. 125.

In Auguſt 1774, Dr. Prieſtley diſcovered dephlogiſticated air. The circumſtances which led him to the diſcovery, were his having always procured inflammable air from ſpirit of ſalt, by adding to it ſpirit of wine, oil of olives, oil of turpentine, charcoal, phoſphorus, bees wax, and even ſulphur. Hence he ſuſpected, that the common might be compoſed of ſome kind of acid united with phlogiſton. On this ſuppoſition he extracted air from mercurius calcinatus *per ſe*, by expoſing it to the focus of a burning-glaſs 12 inches in diameter; and, having repeated the experiment with red precipitate and minium, he found, that though a quantity of fixed air was always produced, yet after that was ſeparated, the remainder ſupported flame much more vigorouſly than common air; for a candle burned in it with a flame very much enlarged, and with a crackling noiſe, at the ſame time that it appeared fully as much diminiſhed by the teſt of nitrous air. When he concluded, that it was reſpirable; and, on making the experiment, found that it actually was ſo, for a mouſe lived a full half hour in a quantity of this fluid; which, had it been common air, would only have kept it alive half that time. Nor did the animal ſeem to be otherwiſe injured than by the cold; as it preſently revived on bringing it near the fire, and the remainder of the air ſtill appeared better than that of the atmoſphere, when the teſt of nitrous air was applied to it.

This pure kind of air being diſcovered, the doctor next proceeded to name it dephlogiſticated, from his opinion that common air, in the act of burning, abſorbed phlogiſton; of conſequence, he ſuppoſed, that which abſorbed the moſt, or which moſt vigorouſly and for the greateſt length of time ſupported flame, was ſuppoſed to contain the ſmalleſt quantity of this ſubſtance. In the courſe of his inquiries why this kind of air comes to be ſo much dephlogiſticated, he fell upon a method of extracting it from a great variety of ſubſtances; viz. by moiſtening them with ſpirit of nitre, and then diſtilling them with a ſtrong heat. Thus he obtained it from flowers of zinc, chalk, quick lime, ſlacked lime, tobacco-pipe clay, flint, Muſcovy talcs, and even glaſs. He then found, that by ſimply diſſolving any metal in the nitrous acid, and then diſtilling the ſolution, he could obtain very pure air; and Mr. Warltire found even the trouble of diſtillation unneceſſary; nothing more being requiſite than to moiſten red lead with the ſpirit of nitre, and then pour upon it the oil of vitriol, which inſtantly diſengaged the dephlogiſticated air without applying any more heat than what was generated by the mixture.

As the nitrous acid was univerſally concerned in the firſt proceſſes for obtaining this kind of air, it was for ſome time generally believed to be a peculiar property of that acid alone to produce it; but Dr. Prieſtley ſoon found, that it might not only be procured where no nitrous acid was employed, but where the ſubſtances were treated with vitriolic acid. It was indeed evident, from the very firſt experiment, that nitrous acid was not eſſentially neceſſary; ſince pure air was procured from precipitate *per ſe*, in the preparation of which no nitrous acid is employed. The Abbé Fontana found, that 192 grains of this ſubſtance yielded 26½ cubic inches of dephlogiſticated air, at the ſame time that the weight of it was reduced to $178\frac{7}{8}$ grains, which is nearly the weight of that quantity of air. It had formerly been obſerved, that the weight of mercury is augmented during its converſion into precipitate *per ſe*, as that of lead is by its converſion into minium. The experiments juſt now mentioned ſhow, that during this proceſs the air is decompounded; the pure dephlogiſticated part of it being abſorbed by the metal, and appearing again on the application of heat; and the ſame appears to be the caſe with red lead, from the experiment of Mr. Warltire already mentioned. With regard to this laſt ſubſtance, however, a very great ſingularity is obſerved; viz. that when newly prepared it yields none at all, and even for ſome time after the produce is much ſmaller than when it has been long kept. The reaſon of this ſeems to be, that the minium ſtill contains a conſiderable quantity of phlogiſton, which flies off into the atmoſphere by long keeping, a larger quantity of the dephlogiſticated part of the atmoſphere being imbibed at the ſame time. The mode of applying heat has alſo a very conſiderable effect on the quantity of air produced.

By heat alone, Doctor Prieſtley found, that ſedative ſalt, manganeſe, lapis calaminaris, and the mineral called *lapis ponderoſus, wolfram*, or *tungſten*, would yield dephlogiſticated air; the firſt indeed in very ſmall quantity, and ſometimes even of a quality very little ſuperior to common air.

In his experiments with the nitrous acid, as it had conſtantly been found, that by pouring on more nitrous acid on the reſiduum, and repeating the operation, more dephlogiſticated air might be obtained, the doctor determined to try whether the ſame would not hold good with vitriolic acid alſo. The ſame product he obtained from blue vitriol, ſolution of copper in the vitriolic acid, and from a ſolution of mercury in that acid. From the later experiments of Mr. Lavoiſier, however, it appears that the Doctor's proceſs had not been conducted with ſufficient care; as from two ounces of the dry ſalt formed by a combination of vitriolic acid with mercury, the former obtained 6 drachms 12 grains of running mercury, beſides 3 drachms 58 grains of mercurial ſublimate of two different colours. Dephlogiſticated air was likewiſe obtained from pure calx of tin, or putty, mixed with oil of vitriol; but none in any trial with the marine acid, excepting when it was mixed with minium; in which caſe the air obtained was probably that which the minium would have yielded without any addition.

The reſult of all theſe, and innumerable other experiments made by philoſophers in different countries, was, that dephlogiſticated air may be obtained from a vaſt variety of mineral and metallic ſubſtances by means of the vitriolic and nitrous acids. It now remained only to diſcover in what manner this fluid, ſo eſſentially neceſſary to the ſupport of animal life, is naturally produced in quantities ſufficient for the great expence of it throughout the whole world, by the breathing of animals, the ſupport of fires, &c. This diſcovery, indeed, had been made before even the exiſtence of dephlogiſticated air itſelf was known.

Dr. Prieſtley, after having tried various methods of purifying contaminated air unſucceſsfully, found at laſt, that ſome kinds of vegetables anſwered this purpoſe very effectually; for which diſcovery he received the thanks of the Royal Society. Among the vegetables employed on this occaſion, he found mint anſwer the purpoſe very effectually. "When air," ſays he, "has been freſhly and ſtrongly tainted with putrefaction, ſo as to ſmell through the water, ſprigs of mint have preſently died upon being put into it, their leaves turning black; but if they do not die preſently, they thrive in a moſt ſurpriſing manner. In no other circumſtances have I ſeen vegetation ſo vigorous as in this kind of air, which is immediately fatal to animal life. Though theſe plants have been crowded in jars filled with this kind of air, every leaf has been full of life; freſh ſhoots have branched out in various directions, and grown much faſter than other ſimilar plants growing in the ſame expoſure in common air." Having in conſequence of this obſervation rendered a quantity of air thoroughly noxious, by mice breathing and dying in it, he divided it into two receivers inverted in water, introducing a ſprig of mint into one of them, and keeping the other receiver unaltered. About eight or nine days after, he found that the air of the receiver into which he had introduced the ſprig, had become reſpirable; for a mouſe lived very well in this, whereas it died the moment it was put into the other.

Having tried the power of ſeveral ſorts of vegetables upon air infected by reſpiration or by the burning of candles, he found that it was generally rendered worſe by their vegetation; and the longer the plants were kept in the infected air, the more they phlogiſticated air; though in ſeveral caſes it was undoubtedly meliorated, eſpecially by the ſhoots of ſtrawberries and ſome other plants, introduced into the vials containing foul air, and inverted in water, which were placed near them, whilſt their roots continued in the earth in the garden. Sometimes the infected air was ſo far mended by the vegetation of plants, that it was in a great meaſure turned into dephlogiſticated air. "On the whole," ſays Dr. Prieſtley, "I ſtill think it probable, that the vegetation of healthy plants, growing in ſituations natural to them, have a ſalutary effect on the air in which they grow. For one inſtance of the melioration of air in theſe circumſtances ſhould weigh againſt an hundred in which the air is made worſe by it, both on account of the diſadvantages under which all plants labour, in the circumſtances in which theſe experiments muſt be made, as well as the great attention and many precautions that are requiſite in conducting ſuch a proceſs."

At the time Dr. Prieſtley made theſe experiments, he ſuppoſed the air was meliorated merely by the abſorption of phlogiſton from that which had been tainted; but the experiments of Dr. Ingenhouſz, made in 1779, ſhewed that this was accompliſhed, not only by the abſorption juſt mentioned, but by the emiſſion of dephlogiſticated air. He obſerved in general, that plants have a power of correcting bad air, and even of improving common air in a few hours, when expoſed to the light of the ſun; but, in the night time, or when they are not influenced by the ſolar rays, they nontaminate the air. This property, however, does not belong in an equal degree to all kinds of plants: nor is it poſſible to diſcover by the external properties of a plant, whether it be fit for this purpoſe or not; as ſome which have a bad ſcent, and are entirely unfit for food, ſhew themſelves much ſuperior to others whoſe external appearance would ſeem preferable. His method of making the experiment was, to fill a vial with air, fouled either by reſpiration or combuſtion; after which a ſprig of any plant was introduced, by paſſing it through the water in which the vial was immerced. The vial was then ſtopped; or it was removed into a ſmall baſon full of water, and expoſed to the ſun, or ſituated in ſome other proper place as occaſion required. Air phlogiſticated by breathing, and in which a candle could not burn, after being expoſed to the ſun for three hours, with a ſprig of peppermint in it, was ſo far corrected, as to be again capable of ſupporting flame. The following experiment, however, made with a muſtard plant, may be looked upon as deciſive: a plant of this kind was put into a glaſs receiver containing common air, and its ſtem cut off even with the mouth of the receiver. The veſſel was then inverted in an earthen pan, containing ſome water to keep the plant alive, and the whole apparatus was ſet over-night in a room. Next morning the air was found ſo much contaminated, that it extinguiſhed the flame of a wax taper. On expoſing the apparatus to the ſun for a quarter of an hour, the air was found to be ſomewhat corrected; and after an hour and an half it was ſo far improved, that by the teſt of nitrous air it appeared conſiderably better than common air.

It appears from Dr. Phillips's experiments, that dephlogiſticated air, in very conſiderable quantity, may, in certain circumſtances, be procured from water alone. The ſubſtance of theſe is, that water, eſpecially pump water, when expoſed to the light of the ſun, emits air ſlowly: but after ſome time a green matter appears on the bottom and ſides of the glaſs; after which it emits very pure air in great quantities, and continues to do ſo for a very long time, even after the green matter has ſhewn ſome ſymptoms of decay by becoming yellow. He obſerved, that the water which naturally contained the greateſt quantity of fixed air, yielded alſo the greateſt quantity of that which was dephlogiſticated; but that the quantity of the latter much exceeded that of the fixed air contained even in any water. The light of the ſun was found to be an eſſential requiſite in the formation of this air, as very little, and that of a much worſe quality, was produced in the dark.

Some poiſonous plants, as the hyoſcyamus, lauro-ceraſus, nightſhade, the tobacco-plant, a triplex vulvaria, cicuta aquatica, and ſabina, were found very fit for the purpoſe of producing dephlogiſticated air: but the pureſt kind of air was extracted from the aquatic vegetables, the turpentine trees, and eſpecially from the green matter he collected in a ſtone trough which was kept continually filled with water from a ſpring near the high road. The purity of this dephlogiſticated air, he ſays, was equal, if not ſuperior, to that procured by the beſt chemical proceſſes; as it ſometimes required eight times its own quantity of nitrous air to ſaturate it. All parts of the plants were not found equally proper for the production of dephlogiſticated air; the full grown leaves yielded it in greateſt quantity and purity, eſpecially from their under ſurface. It was alſo procured from the green ſtalks. One hundred leaves of Naſturtium Indicum put into a jar holding a gallon, filled with ordinary pump water, and expoſed from 10 to 12 o'clock, yielded as much air as filled a cylindrical jar four inches and an half in length, and one and three quarters in breadth. On removing this quantity of air, and expoſing them again to the ſun till ſeven o'clock, about half as much was produced, of a quality ſtill ſuperior to the former; and next morning by eleven o'clock they yielded as much more of an equal quality.

The roots of plants generally yield bad air, and at all times contaminate common air, a few only excepted. Flowers and fruits, in general, yield a very ſmall quantity of noxious air, and contaminate a great quantity of common air at all times, eſpecially in the night, and when kept in the dark. Two dozen of young French beans, kept in a quart jar of common air for a ſingle night, contaminated the air to ſuch a degree, that a very lively chicken died by being confined in it in leſs than half a minute.

The obſervations of Dr. Ingenhouſz, on the whole, ſays Mr. Cavallo, clearly ſhew, "that the vegetation of plants is one of the great means employed by nature to purify the atmoſphere, ſo as to counteract, in a great meaſure, the damage done by animal reſpiration, combuſtion, &c. It may only be ſaid, that vegetation does not appear to be ſufficient to remedy entirely that damage." The

Doctor, however, ſpeaks very highly of the powers of vegetables in this reſpect. He informs us, that their office in yielding dephlogiſticated air begins a few hours after the ſun has made his appearance in the horizon, or rather after it has paſſed the meridian, and ceaſes with the cloſe of day; excepting ſome plants which continue it a ſhort time after ſun-ſet: the quantity of dephlogiſticated air, yielded by plants in general, is greater in a clear day than when it is ſomewhat cloudy. It is alſo greater when the plants are more expoſed to the ſun, than when they are ſituated in ſhady places. He obſerves, moreover, that the damage done by plants in the night is more than counterbalanced by the benefit they afford in the day time.

After the publication of Dr. Ingenhouſz's experiments, it became generally believed, that the atmoſphere was meliorated by the common proceſs of vegetation, and that plants abſorbed the phlogiſtic part as their food, diſcharging the pure dephlogiſticated air as an excrement; which is juſt the reverſe of what happens to animals, who abſorb the pure part in reſpiration, and reject the phlogiſtic. In the Philoſophical Tranſactions for 1787, however, we find a number of experiments related by Sir Benjamin Thompſon, which ſeems to render this matter dubious. One very conſiderable objection is, that the green matter, already mentioned in Dr. Prieſtley's experiments, when carefully obſerved by a good microſcope, appears not to be of a vegetable, but of an animal nature. The colouring matter of the water, ſays he, is evidently of an animal nature; being nothing more than the aſſemblage of an infinite number of very ſmall, active, oval-formed animalculus, without any thing reſembling *tremella*, or that kind of green matter or water-moſs which forms upon the bottom and ſides of the veſſel when this water is ſuffered to remain in it for a conſiderable time, and into which Dr Ingenhouſz ſuppoſes the animalculus above mentioned to be actually transformed.

This gentleman has alſo found, that ſeveral animal ſubſtances, as well as vegetables, have a power of ſeparating dephlogiſticated air from water when expoſed to the light of the ſun, and that for a very great length of time. Not that the ſame quantity of water will always continue to furniſh air; but the ſame animal ſubſtance being taken out, waſhed, and put into freſh water, ſeems to yield dephlogiſticated air, without any kind of limitation.

Raw ſilk poſſeſſes a remarkable power of this kind. To determine it, Sir Benjamin introduced 30 grains of this ſubſtance, previouſly waſhed in water, into a thin glaſs globe $4\frac{1}{2}$ inches in diameter, having a cylindrical neck $\frac{3}{4}$ths of an inch wide, and twelve inches long, inverting the globe into a jar filled with the ſame kind of water, and expoſing it to the action of the ſun in the window. It had not been ten minutes in this ſituation, when the ſilk became covered with an infinite number of air-bubbles, gradually increaſing in ſize, till, at the end of the two hours, the ſilk was buoyed up, by their means, to the top of the water. By degrees they began to ſeparate themſelves, and form a collection of air in the upper part of the globe; which, when examined by the teſt of the nitrous air, appeared to be very pure. In three days he had collected $3\frac{1}{4}$ cubic inches of air; into which a wax-taper being introduced, that had juſt before been blown out, the wick only remaining red, it inſtantly took fire, and burned with a bright and enlarged flame. The water in the globe appeared to have loſt ſomething of its tranſparency, and had changed its colour to a very faint greeniſh caſt, having at the ſame time acquired the ſmell of raw ſilk. This was ſeveral times repeated with freſh water, repeating the ſame ſilk, and always with a ſimilar reſult; but with this difference, that when the ſun ſhone very bright, the quantity of air produced was not only greater, but its quality ſuperior to that yielded when the ſun's rays were feeble, or when they were frequently intercepted by flying clouds. This air, however, (ſays he), was always not only much better than common air, but even than that produced by the freſh leaves of plants expoſed in water to the ſun's rays in the experiments of Dr Ingenhouſz; and, under the moſt favourable circumſtances, it was ſo good, that one meaſure of it required four of nitrous air to ſaturate it, and the whole five meaſures were reduced to 1.35.

An experiment was next made in order to determine the effect of darkneſs upon the production of air: and in this caſe only a few inconſiderable bubbles were formed, which remained attached to the ſilk; nor was the caſe altered by removing the globe into a German ſtove. Some ſingle bubbles, indeed, had detached themſelves from the ſilk and aſcended to the top, but the air was in too little quantity to be meaſured or proved. The medium heat of the globe, when expoſed to the ſun's rays, was about 90° of Fahrenheit, though ſometimes it would riſe as high as 96; but air was frequently produced, when the heat did not exceed 65 and 70°. On reverſing this experiment, in order to try the effect of light without heat, it was found, that by plunging the globe into a mixture of ice and water, which brought it to the temperature of about 50° of Fahrenheit, the produce of air was diminiſhed, though it ſtill continued in conſiderable quantity.

The effect of artificial light, inſtead of that of the ſun, was next tried. For this purpoſe all the air was removed from the globe; and its place being ſupplied with a quantity of freſh water, ſo as to render it quite full, it was again inverted in the jar, and removed into a dark room ſurrounded with ſix lamps and reflectors; ſix wax candles were alſo placed at different diſtances from three to ſix inches from it, and diſpoſed in ſuch a manner as to throw the greateſt quantity of light poſſible upon the ſilk, taking care at the ſame time that the water ſhould not acquire a greater heat than 90°. In this ſituation the ſilk began to be covered with air-bubbles in about ten minutes; and in ſix hours as much was collected as could be proved by nitrous air, when it was found to be very pure. A freſh-gathered, healthy leaf of a peach tree, and a ſtem of the pea plant with three leaves upon it, furniſhed air by expoſure to the ſame light, but in ſmaller quantities than by the action of the ſolar rays. The air produced in the dark, in whatever manner procured, was always in too ſmall quantity to be meaſured.

In order to diſcover the comparative fineneſs of air produced from vegetables and from raw ſilk, a ſmall quantity of air from the ſtem of a pea-plant, which had four healthy leaves upon it, was proved with nitrous air, and found greatly inferior to that from raw ſilk and ſeveral of the ſubſtances already mentioned. An entire plant of houſewort, of a moderate ſize, furniſhed only three-thirds of a cubic inch of air in ſeven hours, and that greatly inferior to common air; but the leaves alone afforded a much greater quantity, and of a quality greatly ſuperior.

The experiments of Dr. Prieſtley alluded to were thoſe in which inflammable air was ſuppoſed by Mr. Lavoiſier to be procured from water, by paſſing its ſteam through red-hot iron tubes. It was ſoon diſcovered, however, by Dr. Prieſtley, that this inflammable air did not proceed from the water, but from the iron of the tube; and might be obtained by tranſmitting aqueous vapour through charcual or iron placed in tubes of copper, glaſs, or earthen ware, made red-hot, but not through theſe tubes by themſelves. In this caſe, the loſs of the water employed exceeded that of the inflammable air produced in the proportion of 1.3 to 2; and the iron which had thus abſorbed the water appeared exactly ſimilar to that which had been burned in dephlogiſticated air in the manner already related. His concluſions from thence are theſe: "Since iron gains the ſame addition of weight by being melted in dephlogiſticated air, and alſo by the addition of water when red hot, and becomes, as I have already obſerved, the ſame ſubſtance in all reſpects, it is evident that this air or water, as exiſting in the iron, is the very ſame thing; and this can hardly be explained but on the ſuppoſition that water conſiſts of two kinds of air, viz. inflammable and dephlogiſticated."

Of theſe proceſſes he gives the following explanation: "When iron is heated in dephlogiſticated air, we may ſuppoſe, that, tho' part of its phlogiſton eſcapes, to enter into the compoſition of the ſmall quantity of fixed air which is then procured, yet enough remains to form water with the dephlogiſticated air which it has imbibed, ſo that this calx conſiſts of the intimate union of the pure earth of iron and of water; and therefore, when the ſame calx, thus ſaturated with water, is expoſed to heat in inflammable air, this air enters into it, deſtroys the attraction between the water and the earth, and revives the iron, while the water is expelled in its proper form."

The whole of the doctor's opinions on the component parts of this kind of air, however, are ſummed up in the following ſentence in his Obſervations relating to Theory. "The only kind of air that is now thought to be properly elementary, and to conſiſt of a ſimple ſubſtance, is dephlogiſticated air; with the addition at leaſt of the principle of heat, concerning which we know very little; and as it is not probable that this adds any thing to the weight of bodies, it can hardly be called an element in their compoſition. Dephlogiſticated air appears to be one of the elements of water, of fixed air, of all the acids, and many other ſubſtances, which, till lately, have been thought to be ſimple."

The experiments of the French philoſophers were of the ſame nature with thoſe of Mr. Cavendiſh, but conducted on a larger ſcale. The inference drawn from them was the ſame with that already mentioned, viz. that dephlogiſticated and inflammable air in all caſes are the two conſtituent parts of water. This opinion is adopted by Mr. Kirwan in his Treatiſe on Phlogiſton. "The experiments of Mr. Cavendiſh, and of Mr. Monge," ſays he, "appear to me to leave no room to doubt, that when very pure dephlogiſticated and inflammable air are inflamed, the product is mere water; for when theſe airs are employed in the proper proportion, only 0.02 of the mixture of both airs retains its aerial form. Now it is impoſſible to ſuppoſe that all the water obtained pre-exiſted in theſe airs; that is, that 49 parts in 50 were mere water.

Notwithſtanding theſe poſitive concluſions, however, by ſome of the moſt reſpectable names in this country, the evidences adduced have been unſatisfactory to ſome French chemiſts; who maintain, that Meſſrs. Cavendiſh, Prieſtley, and Kirwan, are totally miſtaken with regard to the production of water from dephlogiſticated and inflammable air; contending, that the water obtained had previouſly exiſted in the air, and was not originally produced in the operation. The fact, indeed, becomes ſomewhat dubious from ſome experiments related by Dr. Prieſtley himſelf, and of which we ſhall now proceed to give an account.

One conſequence of the hypotheſis in queſtion is evident, that if water really be produced by the dephlagration of either dephlogiſticated or common air with inflammable air, the quantity of liquid obtained ought to increaſe in proportion to the quantity of the two airs conſumed, and that without any limitation. This, however, is not the caſe, as Dr. Prieſtley has obſerved. He had ſucceeded indeed with ſcales of iron and copper, and in the experiment with the latter, the production of water was ſo copious, that when only 3½ ounce meaſures of air were abſorbed, the water ſtood in drops on the inſide of the veſſel, and ſome of theſe ran down it. Water was alſo procured by firing dephlogiſticated and inflammable air from iron by the electric ſpark in a cloſe veſſel, an experiment ſimilar to thoſe made by Mr. Lavoiſier at Paris. In his firſt experiment he put 3.75 ounce meaſures of a mixture of air, of which one-third was dephlogiſticated and two-thirds inflammable air from iron, in a cloſe veſſel, and, after the exploſion, found in it one grain of moiſture; but on repeating the experiment with half as much dephlogiſticated as inflammable air, he could perceive no ſign of moiſture. The greateſt difficulty, however, which he ſays he ever met with reſpecting the preceding theory, aroſe from his never having been able to produce any water when he revived red precipitate in inflammable air, or at leaſt no more than might have been ſuppoſed to be contained in the inflammable air as an extraneous ſubſtance.

In order to make the experiments with the ſcales of iron and that with the red precipitate as much alike as poſſible, and compare them both to the greateſt advantage, he made them one immediately after the other, with every circumſtance as nearly the ſame as he could. The inflammable air was the ſame in both experiments, and both the ſcales of iron and red precipitate were made as dry as poſſible. They were heated in veſſels of the ſame ſize and form, and equally confined by dry mercury; and yet, with the former, water was produced as copiouſly as before, viz. running down the inſide of the veſſel in drops, when only four ounce meaſures of inflammable air were abſorbed: and only 0.75 of an ounce meaſure remained, there was hardly any ſenſible quantity of water produced, "certainly," ſays he, "not one-tenth of what appeared in the experiment with the ſcales of iron. In this experiment there can be no doubt but that the dephlogiſticated air produced from the red precipitate united with the inflammable air in the veſſel; and as no water equal to the weight of the two kinds of air was produced, they muſt have formed ſome more ſolid ſubſtance, which, in the ſmall quantities I was obliged to uſe, could not be found.

"The difficulty, with reſpect to what becomes of the two kinds of air, was not leſſened by the attempts which I made to collect all that I could from repeated decompoſitions of inflammable and dephlogiſticated air in a cloſe veſſel. As I had produced water in this proceſs, when no more than a ſingle exploſion was made at a time, I thought that by continuing to make exploſions in the ſame veſſel, the water would not fail to accumulate till any quantity might be collected; and I intended to have collected a conſiderable part of an ounce. And as I ſhould know exactly what quantity of air I decompoſed, I had no doubt of being able to aſcertain the proportion that the water and air bore to each other. With this view a mixture was made of a large quantity of air, one third dephlogiſticated, and two thirds inflammable, from iron and oil of vitriol. But though I had a ſenſible quantity of water at the firſt exploſion (in each of which between four and five ounce meaſures of the mixture of air were uſed) I was ſurpriſed to perceive no very ſenſible increaſe of the quantity of water on repeating the exploſions. Having therefore expended 48 ounce meaſures of the mixture, the proceſs was diſcontinued; and, collecting the water with all the care I could, I found no more than three grains, when there ought to have been eleven.

"In this proceſs the inſide of the veſſel was always very black after each exploſion; and when I poured in the mercury after the exploſion, though there was nothing viſible in the air within the veſſel, there iſſued from the mouth of it a denſe vapour. This was the caſe, though I waited ſo long as two minutes after any exploſion, before I proceeded to put in more mercury in order to make another; which, if the vapour had been ſteam, would have been time more than ſufficient to permit it to condenſe into water. I even perceived this vapour when I had a quantity of water in the veſſel, and the exploſion was conſequently made over it, as well as in contact with the ſides of the veſſel which were wetted with it; ſo that, as this vapour had paſſed through the whole body of water when the veſſel was inverted, it is probable that it muſt have conſiſted of ſomething elſe than mere water. But I was never able to collect any quantity of it, though it muſt have been ſomething procured by the union of the two kinds of air."

In order to collect a quantity of this vapour, he contrived an apparatus, which, by diffuſing it through a thin glaſs veſſel, he ſuppoſed would condenſe all the contents, whether fluid or ſolid; but after repeating the experiment as carefully as poſſible, by taking 20 exploſions, and repeating the whole ſeveral times over, he could find nothing in the veſſel beſides a ſmall quantity of water, which, added to that in the ſtrong veſſel, came far ſhort of the weight of the air that was decompoſed.

"All the conjecture," ſays he, "that I can advance, in order to explain this phenomenon is, that ſince ſoot yields pure air, part of the ſoot is formed by the union of the dephlogiſticated air in the atmoſphere, and the inflammable air of the fuel: but *ſmoke*, which contains much *ſoot*, is ſoon diſperſed, and becomes inviſible in the open air. Such, therefore, may be caſe here. The ſoot formed by the union of the two kinds of air may be diffuſed through the air in the veſſel in which they are exploded, and be carried inviſibly into the common atmoſ-phere; which may account for my not being able to collect any quantity of it in this apparatus."

Not diſcouraged by this bad ſucceſs, the Doctor attempted to collect this volatile matter by means of a quantity of water incumbent upon the mercury in the ſtrong glaſs veſſel in which the exploſions were made, though he had found that part of it could eſcape through the water. He decompoſed a great quantity of the two kinds of air in theſe circumſtances; and preſently found that water became very cloudy, and was at length filled with a blackiſh matter. This he collected, and found that it remained perfectly black upon the earthen veſſel in which the water containing it was evaporated; which would not have been the caſe if the blackiſh matter in the water had been that powder of mercury which is produced by agitating it in pure water: For that black maſs always became white running mercury the moment the water was evaporated from it. If a ſufficient quantity of this matter could have been procured, he could have ſatisfied himſelf whether it was ſoot or not.

"That water, in great quantities (ſays he), is ſometimes produced from burning inflammable and dephlogiſticated air, is evident from the experiments of Meſſrs. Cavendiſh and Lavoiſier. I have alſo frequently collected conſiderable quantities of water in this way, though never quite ſo much as the weight of the two kinds of air decompoſed. My apparatus for this purpoſe was the following: into the mouth of a large glaſs balloon I introduced a tube, from the orifice of which there continually iſſued inflammable air from a veſſel containing iron and oil of vitriol. This being lighted, continued to burn like a candle. Preſently after lighting it, the inſide of the balloon always became cloudy, and the moiſture ſoon gathered in drops, and ſettled in the lower part of the balloon. To catch what might iſſue in the form of vapour, in the current of air through the balloon, I placed the glaſs tube, in which I always found ſome water condenſed. It is very poſſible, however, that in both theſe modes of experimenting, the water may be converted into a kind of vapour, which is very different from ſteam, and capable of being conveyed a great way through air, or even water, without condenſation along with the air with which it is mixed; and on this account it may not be poſſible, in either of theſe modes of experimenting, to collect all the water into which the two kinds of air may be converted. The nature of this kind of vapour into which water may be changed, and which is not readily condenſed by cold, is very little underſtood, but well deſerves the attention of philoſophers.

That the water collected in the balloon comes from the decompoſition of the air, and not from the freſh air circulating through it, was evident from placing balls of hot iron in the place of the flame, and finding that, though the balloon was as much heated by them as by the flame of the burning of the inflammable air, and conſequently there muſt have been the ſame current of the external air through it, no moiſture was found in the balloon.

DEFINITION III.

As it has been obſerved, that air was diminiſhed, in ſome caſes at leaſt, by burning, univerſally by reſpiration, and by ſome other proceſſes, it was imagined that phlogiſton was a body of ſuch a ſingular nature, that when mixed with air, it always diminiſhed its bulk, inſtead of enlarging it, which might have been more naturally expected from the mixture of any vapour whatever. It was alſo ſuppoſed by ſome, that the phlogiſton was not only entirely devoid of gravity, but that it was a principle of poſitive levity; ſo that the abſolute weight of bodies was diminiſhed by an union with it, and augmented when it was expelled, though their ſpecific gravity was diminiſhed. Various other properties were attributed to phlogiſton; ſuch as that of giving elaſticity to air, of conſtituting flame by a chemical combination with air, &c. Its emiſſion into the atmoſphere was ſuppoſed to be always attended with a diminution of air; and therefore, all proceſſes in which air was diminiſhed and become noxious, ſuch as that by liver of ſulphur, a mixture of iron filings and brimſtone, &c. were called phlogiſtic proceſſes. Reſpiration of animals was taken into the ſame account; but neither in this, nor in combuſtion, was it allowed that any kind of vital ſpirit was abſorbed by the blood, or ſeparated from the air by the burning body. On the contrary, it was ſtrenuouſly argued, that all this was performed by the *emiſſion* of *phlogiſton* from the lungs or the inflamed ſubſtance, which depraved the air, and diminiſhed it in bulk; and as all air was ſuppoſed to contain phlogiſton, it was likewiſe imagined, that in all caſes where air was mended, as by the growing of vegetables, or agitation in water, the emendation was accompliſhed, not by the emiſſion of any thing into the atmoſphere, but by the mere abſorption of phlogiſton. In other reſpects this ſubſtance was thought to be an exceedingly powerful principle in nature; the light of the ſun itſelf and the electric fluid being ſaid to be modifications of it, the different kinds of aris to be *phlogiſtic vapours*, &c.; ſo that the whole ſyſtem of nature ſeemed ready to be abſorbed by it at once.

The formidable powers of this principle were firſt checked by the diſcoveries of Mr. Lavoiſier, though the latter erred equally on the contrary ſide; and not content with keeping the phlogiſtic principle within due bounds, would needs deny its exiſtence altogether. In a treatiſe publiſhed in the year 1782, he firſt impugns Dr. Prieſtley's theory of reſpiration, and denies that "the reſpiration of animals has the property of phlogiſticating air in a manner ſimilar to what is effected by the calcination of metals and many other chemical proceſſes; and that it ceaſes not to be reſpirable till the inſtant when it becomes ſurcharged, or at leaſt ſaturated with phlogiſton."

In order to diſprove this aſſertion, he introduced four ounces of mercury to 50 cubic inches of common air, propoſing to calcine the metal by keeping it for 12 days in a heat almoſt equal to that which is neceſſary to make it boil. After the expiration of the appointed time, 45 grains of precipitate *per ſe* were formed, and the air in the veſſel was diminiſhed by about one-ſixth of its volume. In this ſtate it did not precipitate lime-water; but inſtantly extinguiſhed candles, and killed animals immerſed in it; no longer affording any red vapours, or being diminiſhed by mixture with nitrous air: on diſtilling the precipitate produced, about as much dephlogiſticated air was obtained as had been left by the common air in the calcination; and by recombining this with the noxious air left in the veſſel, he recompoſed a fluid nearly of the ſame goodneſs wlth common air. Hence he draws the following concluſions: 1. That 5-6ths of the air we breathe are mephitic, or incapable of ſupporting the reſpiration of animals, or the inflammation and combuſtion of bodies. 2. That the ſurplus, or only 1-5th of the volume of atmoſpherical air, is reſpirable. 3. That in the calcination of mercury, this metallic ſubſtance abſorbs the ſalubrious part, leaving only the mephitic portion of the air. 4. That by reuniting theſe two portions which had been ſeparated, we can recompound air ſimilar to that of the atmoſphere.

To determine the effects of reſpiration upon air, a live ſparrow was placed under a glaſs receiver, filled with common air and inverted in mercury, containing 31 cubic inches. In a quarter of an hour it became agitated, and in 55 minutes died convulſed. Notwithſtanding the heat of the animal, which neceſſarily, at firſt, rarefied the air in the receiver, there was a ſenſible diminution of its bulk; which, at the end of 15 minutes, amounted to one-fortieth: but, inſtead of increaſing afterwards, the diminution became ſomething leſs in about half an hour; and when the animal was dead, and the air in the reciever had recovered the temperature of the room where the experiment was made, the diminution did not appear to exceed one-ſixtieth part. This air which had been reſpired by the ſparrow, though in many reſpects ſimiliar to that in which the mercury had been calcined, differed from it in this reſpect, that it precipitated lime-water, and, by introducing cauſtic fixed alkali to it, was reduced one-ſixth in bulk by the abſorption of fixed air; after which it appeared exactly the ſame with that produced by the calcination of mercury or other metals; and atmoſpherical air was recompoſed by mixing this with pure dephlogiſticated air in the proportions already mentioned.

That common air is compounded of two kinds of elaſtic fluids, Mr. Scheele has proved by the following experiment: "I diſſolved (ſays he) one ounce of alkaline liver of ſulphur in eight ounces of water; of this ſolution I poured four ounces into an empty bottle, whoſe capacity was 24 ounces, and worked it well; then I turned the bottle, immerſed its neck into a ſmall veſſel with water, and kept it in this poſition a fortnight. The ſolution had partly loſt its red colour, and ſome ſulphur had been precipitated from it during this time. After this I put the bottle in the ſame poſition in a larger veſſel with water, keeping the mouth and neck under water, and the bottom of the bottle above water, and thus I drew the cork under water, which immediately ruſhed with violence into the bottle. On examining the quantity of water in the bottle, it was found, that during this fortnight, ſix parts out of 20 of air were loſt." On repeating the experiment with the ſame materials, and in the ſame bottle, only four parts out of 20 were loſt by ſtanding a week, and more than ſix after four months.

From theſe experiments and many others ſimilar, it appears that the doctrine of phlogiſton had been carried too far by Dr. Prieſtley and other Britiſh philoſophers, and that the air conſiſts of two kinds of fluids; one perfectly ſalutary, and friendly in the higheſt degree to animal life; the other altogether unfit for it. Theſe two appear incapable of being converted directly into one another by any proceſs: for though both of them are deſtructible, yet they are always converted into other ſubſtances; from which, indeed, either the one or the other may be extracted at pleaſure by employing the proper methods. The ſtrongeſt arguments in favour of the tranſmutation of phlogiſticated air into that of a purer kind, were drawn from the purification of noxious air by vegetation, and by agitation in water. In the former caſe, however, it has been obſerved, that this ſeeming purification is no other than an exchange of one air for the other; the vegetables abſorbing the phlogiſticated, and emitting the dephlogiſticated air in its ſtead. With reſpect to the agitation in water, the matter remained more dubious; and it is only in the laſt volume of Dr. Prieſtley's treatiſe that we have any account of this being accompliſhed by an emiſſion of purer air from the water. "In the infancy of my experiments," ſays he, "I concluded, that all kinds of air were brought by agitation to the ſame ſtate; the pureſt air being partially phlogiſticated, and air completely phlogiſticated being thereby made purer; inflammable air alſo loſing its inflammability, and all of them brought into ſuch a ſtate as that a candle would juſt go out in them. This inference I made from all the kinds of air with which I was then acquainted, and which did not require to be confined by mercury, being brought to that ſtate by agitation in a trough of water, the ſurface of which was expoſed to the open air; never imagining that when the air in my jar was ſeparated from the common air by a body of water, generally about twelve inches in depth (adding that within to that without the jar), they could have any influence on each other. I have, however, been long convinced, that, improbable as it then appeared to me, this is actually the caſe."

Phlogiſticated air is now generally believed to be a combination of the nitrous acid with phlogiſton; and that, in its gradual progreſs towards this, which is its ultimate ſtage, it firſt aſſumes the character of phlogiſticated nitrous acid; then of nitrous air, in which it readily parts with its phlogiſton to the atmoſphere; or rather to the dephlogiſticated part of it; and laſtly, it becomes phlogiſticated air, in which the union between the principles is ſo ſtrong, that it cannot be broken by ſimple expoſure to dephlogiſticated air without heat; though the experiments of Mr. Cavendiſh ſhow, that this may be done by means of the electric ſpark, which produces the moſt violent heat we can imagine. See Phil. Tranſ. Vol. 75.

Common air conſiſts of one part of dephlogiſticated and four of phlogiſticated air; ſo that a mixture of five parts of pure dephlogiſticated air and three of common air, is the ſame thing as a mixture of ſeven parts of dephlogiſticated air with three of phlogiſticated.

From the experiments before mentioned, it is evident the chief cauſe of the diminution of air is the converſion of the phlogiſticated kind into nitrous acid; yet it ſeemed not unlikely, that when any liquor containing inflammable matter was in contact with the air in a tube, ſome of this matter might be burnt by the ſpark, and thereby diminiſh the air. In order to determine this, the electric ſpark was paſſed through dephlogiſticated air included between different liquors; and the reſult of the experiments was, that when dephlogiſticated air, containing only 1-20th part of its bulk of phlogiſticated air, was confined between ſhort columns of ſoap-leys, and the ſpark paſſed through it till no farther diminution could be perceived, the air loſt $\frac{28}{80}$ds of its bulk; which is not a greater diminution than might very likely proceed from the decompoſition of the ſmall quantity of phlogiſticated air contained in it, as the dephlogiſticated air might eaſily be mixed with a ſmall quantity of common air while putting into the tube. When the ſame dephlogiſticated air was confined between columns of diſtilled water, the diminution was rather greater than before, and a white powder was formed on the ſurface of the quickſilver beneath: the reaſon of which, in all probability, was, that the acid produced in the operation corroded the quickſilver, and formed the powder; and that the nitrous air produced by that corroſion united to the dephlogiſticated air, and cauſed a greater diminution than would otherwiſe have taken place. When a ſolution of litmus was uſed inſtead of diſtilled water, the ſolution ſoon acquired a red colour; which grew paler as the ſpark was continued, till it became quite colourleſs and tranſparent. The air was diminiſhed by almoſt one-half, and might perhaps have been further diminiſhed had the ſpark been continued. When lime-water was let up into the tube, a cloud was formed, and the air was further diminiſhed by about one-fifth; the remainder was good dephlogiſticated air. In this experiment, therefore, the litmus was, if not burnt, at leaſt decompounded, ſo as to loſe entirely its purple colour, and to yield fixed air; ſo that, though ſoap-leys cannot be compounded by this proceſs, yet the ſolution of litmus can, and ſo very likely might the ſolutions of many other ſubſtances be. But there is nothing in any of theſe experiments which favours the opinion of the air being at all diminiſhed by means of phlogiſton communicated to it by the electric ſpark.

DEFINITION IV.

Van Helmont firſt diſcovered fixed air, which he called *gas ſilveſtre*, from its being emitted in great quantities by burning charcoal. Subſequent diſcoveries ſhow, that a fluid of the ſame kind may be plentifully produced, by fermenting liquor, in almoſt every kind of combuſtion, and naturally generated in vaſt quantities in mines and coal-pits, where it is known by the name of the choak-damp; that it exiſts in a concrete ſtate in alkaline ſalts, chalk, limeſtone, the ſhells of marine animals, magneſia alba, &c. in a very large proportion, conſtituting one half, and ſometimes more of their weight; and that it might always be extracted from the atmoſphere, in unlimited quantity, by expoſing certain ſubſtances to it. On examining the nature of this fluid, it was found ſo manifeſtly acid, that it has now obtained a place among theſe ſubſtances under the name of aërial acid; or, more improperly, cretaceous acid, from its being contained in great quantities in chalk, as has been already mentioned.

Fixed air is the heavieſt of all permanently elaſtic fluids, excepting thoſe derived from the mineral acids. Mr. Kirwan determines it to be to common air as 1500 to 1000, the barometer being at 29.85, the thermometer at 64, and the fixed air being extracted from calcareous ſpar by marine acid, whoſe ſpecific gravity was 1.0145. He obſerves, however, that though this air was obtained in the drieſt manner poſſible, and that the globe which contained it appeared perfectly free from moiſture; yet, when carried into a room 27 degrees colder, the inſide of the globe was covered with dew, which ſoon formed viſible drops. In its concrete ſtate, fixed air is one of the heavieſt bodies in nature. Mr. Kirwan, in the 71ſt volume of the Philoſophical Tranſactions, gives an account of his ingenious method of finding the ſpecific gravity of fixed air in its fixed ſtate, when combined with calcareous earth; from which it appears, that fixed air, in that ſtate, is prodigiouſly concentrated, and, were it poſſible to exiſt by itſelf in that concentrated ſtate, it would be the heavieſt body known, gold and platina excepted.

Fixed air differs conſiderably in its properties from the airs already mentioned. The compound nature of it, and the principles from which it is formed, were firſt diſcovered by Mr. Kirwan; but Dr. Prieſtley was not convinced by the proofs he adduced, till after making ſome experiments of his own. The firſt was, by firing ſhavings of iron in dephlogiſticated air; when he obſerved a conſiderable reſiduum of fixed air, though that in the receiver had been of the pureſt dephlogiſticated kind, and iron could only have yielded inflammable air. The hypotheſis of Mr. Kirwan was ſtill further confirmed by an experiment in which iron-filings, which could only have yielded inflammable air, were mixed with red precipitate, which is known to yield only pure dephlogiſticated air. On heating theſe in a glaſs retort, they gave a great quantity of fixed air, in ſome portions of which nineteen-twentieths were abſorbed by lime-water, and the reſiduum was inflammable; but when the red precipitate was mixed with powdered charcoal, which had been found to yield only inflammable air, the fixed air produced from it was ſo pure that only one-fortieth part remained unabſorbed by water, which is as pure as that generally prepared from chalk and oil of vitriol.

In ſome of theſe experiments it appeared, that three ounce-meaſures of dephlogiſticated air went to the compoſition of two of fixed air: for one ounce of red precipitate gave 60 ounce-meaſures of dephlogiſticated air; and, when mixed with two ounces of iron-filings, it gave about 40 ounce-meaſures of fixed air that were actually abſorbed by water, beſides a reſiduum that was inflammable. The ſame proportion was obtained when half the quantity of materials were made uſe of; but on uſing an ounce of each, only 20 ounce-meaſures of fixed air, including the reſiduum, could be got.

In conſidering this ſubject farther, it occurred to Dr. Prieſtley, that his experiments, in which charcoal was uſed, lay open to an objection, that ſince dry wood, and imperfectly made charcoal, yield fixed air, it might be ſaid, that all the elements of fixed air are contained in charcoal: and though this ſubſtance alone, even with the aſſiſtance of water, will not yield fixed air, this might be effected by treating it with other ſubſtances without their importing any thing to it; eſpecially as the inflammable air procured from charcoal by means of water, appears to contain fixed air when decompoſed with the dephlogiſticated kind. In order to expel all the fixed air from charcoal, he made a quantity of it from dry oak; and pounding it while hot, inſtantly mixed four meaſures of it with one of red precipitate, and putting them into an earthen retort, got, with a heat no greater than what was ſufficient to revive the mercury, a large quantity of air, half of which was fixed. Afterwards the proportion of fixed air was leſs, and at laſt no fixed air at all was obtained; but as the reſiduum was worſe than the common atmoſphere, he is thence inclined to believe, notwithſtanding Mr. Cavendiſh's experiments, that phlogiſticated air may be compoſed of phlogiſton and dephlogiſticated air.

In another experiment he found a better proportion of charcoal and red precipitate. This was by mixing one ounce of precipitate with the ſame quantity of perfect charcoal hot from the retort in which it was made. Putting theſe into a coated retort, he expelled from them, by a ſtrong heat, about 30 ounce-meaſures of air, the whole of which was the pureſt fixed air, leaving only about one-fortieth part unabſorbed by water, and this almoſt perfectly phlogiſticated.

Fixed air may be alſo produced from red precipitate mixed with braſs filings, with zinc, from turbith mineral with iron filings, and from the black powder into which mercury mixed with lead is eaſily converted. In this laſt caſe Dr. Prieſtley ſuppoſes that the fixed air was produced from the dephlogiſticated kind abſorbed by the metals and the phlogiſton of the lead; and this is confirmed by an obſervation that the fixed air always comes firſt in the proceſs, when the phlogiſton is moſt readily ſeparated, but afterwards the produce becomes quite pure and dephlogiſticated. In attempting, however, to increaſe the quantity of fixed air by heating this black powder in dephlogiſticated air, he found only an augmentation of the quantity of dephlogiſticated air, and that of the pureſt kind.

"Perhaps," ſays he, "as deciſive a proof as any of the real production of fixed air from phlogiſton and dephlogiſticated air, may be drawn from the experiments in which I always found a quantity of it when I burned ſulphur in dephlogiſticated air. In one of theſe experiments, to which I gave particular attention, ſix ounce-meaſures and an half of the dephlogiſticated air were reduced to about two ounce-meaſures, and one-fifth of this was fixed air. When both the vitriolic acid and fixed air produced by this operation were abſorbed by water, the remainder was very pure dephlogiſticated air.

That dephlogiſticated air actually enters into the compoſition of the fixed air, is evident from the weight of the latter, which far exceeds that of the charcoal diſperſed in the proceſs. For, in an experiment made, the weight of the fixed air produced was 4.95 grains. Conſequently, ſuppoſing the charcoal to be wholly phlogiſton, as it is very nearly ſo, fixed air may be ſaid to conſiſt of 3.45 parts of dephlogiſticated air, and 1.5 of phlogiſton; ſo that the dephlogiſticated air is more than three times the proportion of phlogiſton in it. I muſt not conclude, however, without obſerving, that, in one experiment, I never failed to produce fixed air; though it is not eaſy to ſee how one of its ſuppoſed elements, viz. dephlogiſticated air, could enter into it. This is by heating iron in vitriolic acid air. In one of theſe experiments, four ounce-meaſures of the vitriolic acid air were reduced to 0.65 of an ounce-meaſure; and of the quantity loſt three and an half meaſures were fixed air abſorbed by lime-water, and the remainder weakly inflammable."

DEFINITION V.

In the year 1767, Mr. Cavendiſh firſt publiſhed the remarkable properties of inflammable air. Its effects, however, had long before been fatally experienced by miners; in whoſe ſubterraneous habitations it is often collected in ſuch quantities as to produce the moſt dreadful effects. It is produced in abundance from putrid animal and vegetable ſubſtances; and, in general, by all thoſe which part with their phlogiſton eaſily. Being much lighter than common air, it always riſes to the top of thoſe places where it is generated; ſo that it cannot be confined except in ſome vaulted place, but always ſtrives to aſcend and mix with the atmoſphere.

Inflammable air is, by itſelf, very noxious, and will inſtantly put an end to animal life; but when mixed with atmoſpherical air, may be breathed in much greater quantity than fixed air. Its great inflammability in this ſtate, however, renders it very dangerous to bring any lights, or even to ſtrike a flint with ſteel, in thoſe places where it abounds. But this only takes place when the inflammable air is mixed with common atmoſpherical or with dephlogiſticated air; in which caſe, the exploſion is much more violent than the former; for pure inflammable air extinguiſhes flame as effectually as fixed or phlogiſticated air.

Beſides the ſubterraneous places already mentioned, this kind of air is found in ditches; over the ſurface of putrid waters, out of which it eſcapes; in burying places; in houſes of office, where putrid animal and vegetable matters are accumulated; and may, by ſtanding or boiling, be extracted from the waters of moſt lakes and rivers, eſpecially thoſe in which great quantities of fermenting and putrefying matters are thrown: and as putrefaction thus ſeems to be the principal ſource of inflammable air, thence happens, that much more of it is produced in warm than in cold climates. In thoſe countries, we are informed by Dr. Franklin, that if the mud at the bottom of a pond be well ſtirred, and a lighted candle brought near to the ſurface of the water immediately after, a flame will inſtantly ſpread a conſiderable way over the water, from the accenſion of the inflammable air, affording a very curious ſpectacle in the night-time.

In colder climates, the generation of inflammable air is not ſo plentiful as to produce this phenomenon; nevertheleſs Mr. Cavallo informs us, that it may be plentifully procured in the following manner, in all the ponds about London. "Fill a wide-mouthed bottle with the water of the pond, and keep it inverted therein; then, with a ſtick, ſtir the mud at the bottom of the pond, juſt under the inverted bottle, ſo as to let the bubbles of air which come out of it enter into the bottle; which air is inflammable. When by thus ſtirring the mud in various places, and catching the air in the bottle until this is filled, a cork or glaſs ſtopper muſt be put over it whilſt ſtanding in water; and then the bottle muſt be taken home, in order to examine the contained inflammable fluid at leiſure."

The great quantity of inflammable air produced in warm climates has given occaſion to ſome philoſophers to ſuppoſe, that it may poſſibly have ſome ſhare in producing certain atmoſpherical meteors. The weak lightnings without any exploſion, which are ſometimes perceived near the horizon in ſerene weather, are by them conjectured to proceed from inflammable air fired by electric exploſions in the atmoſphere. Mr. Volta ſuppoſes that the *ignes fatui* are occaſioned by the inflammable air which proceeds from marſhy grounds, and is ſet on fire by electric ſparks: but theſe phenomena can be accounted for in a more probable manner from the action of the electric fluid itſelf.

This kind of air is more common than any of the other noxious airs; for there is hardly any inflammable ſubſtance on earth, out of which it may not be extracted by one means or other. The fluids, however, which go by the general name of inflammable air, have ſcarce any other property in common to them all, beſides thoſe of inflammability, and being ſpecifically lighter than the common atmoſpherical air. In other reſpects, the differences between them are very conſiderable. The ſcent, weight, power of burning, of preſerving their properties, and the phenomena attending their combuſtion, are by no means the ſame in them all; ſome burning in an exploſive manner; others quietly, and with a lambent flame of a white or blue colour. It is, however, neceſſary to make a proper diſtinction between an inflammable elaſtic fluid or inflammable gas, which may be properly called ſo, and that which is evidently made by combining an inflammable ſubſtance with common air; which being eaſily ſeparable from the air, leaves that fluid in the ſtate it was before. Thus a drop of ether, put into a quantity of common air, mixes itſelf with it, and takes fire on the approach of flame, like a mixture of inflammable and common air; but if the air to which ether is added be waſhed in water, the latter is ſoon ſeparated from it.

Common air becomes alſo inflammable by being tranſmitted through ſeveral eſſential oils; and thus the air contiguous to the plant called fraxinella becomes inflammable in calm and hot weather, by the emiſſion of its inflammable air. By heat alone, a conſiderable quantity of this kind of air may be extracted from moſt inflammable ſubſtances, and even from ſome of the metals. Dr. Hales obtained inflammable air by ſimply diſtilling wax, pitch, amber, coals, peaſe, and oyſter ſhells; and Mr. Fontana informs us, that he obtained a conſiderable quantity of inflammable air from ſpathoſe iron, by the action of fire only applied to it in a mattraſs. Dr. Prieſtley, however, obtained it from a vaſt number of other ſubſtances, by diſtilling them in a gun-barrel; to the extremity of which was luted a tobacco-pipe, or ſmall glaſs tube, with a flaccid bladder tied on the end. He obſerves, that the heat muſt be ſuddenly applied, in order to get a conſiderable quantity of air from theſe ſubſtances. "Notwithſtanding, ſays he, the ſame care may be taken in luting, and in every other reſpect, ſix, or even ten, times more air may be got by a ſudden heat than by a ſlow one, though the heat that is laſt applied be as intenſe as that which was applied ſuddenly. A bit of dry oak, weighing about twelve grains, will generally yield a ſheep's bladder full of inflammable air with a briſk heat, when it will only yield two or three ounce-meaſures if the ſame heat be applied gradually." When he wanted to extract inflammable air from metals, a glaſs was uſed, the focus of which afforded a more intenſe heat than any furnace he could apply; and in this way he obtained inflammable air from ſeveral metals; as iron, braſs, and tin; but with the metallic calces he had no ſucceſs.

Dr. Prieſtley repeated his experiments of procuring inflammable air not only with water, but with other fluids. Sending the vapour of two ounces of ſpirit of wine through a red-hot earthen tube, he obtained 19 0 ounce-meaſures of inflammable air, which burned with a white lambent flame. It contained no fixed air; and 30 ounce-meaſures of it weighed eight grains leſs than an equal quantity of common air. He collected alſo 0.35 of an ounce-meaſure of water. In this experiment, the weight of the water collected was 168 grains, of the inflammable air 633 grains, and that of the ſpirit of wine originally was 821 grains; ſo that as little was loſt in the proceſs as could be expected. Repeating the experiment with vitriolic ether, an ounce of it treated in the ſame manner in an earthen tube almoſt filled with pieces of broken earthen retorts and crucibles, one tenth part of an ounce of water was collected, and 740 ounce-meaſures of inflammable air were procured, without any mixture or fixed air, burning with a white lambent flame like that of wood, and not exploding with dephlogiſticated air. Twenty-nine ounce-meaſures of this weighed five grains leſs than an equal quantity of common air. Vapour of ſpirit of turpentine yielded inflammable air mixed with much black ſmoke, which ſoon collected on the ſurface of the water in the receiver. The ſmell of this air was exceedingly offenſive, and its flame was much leſs luminous than that of the former. Its ſpecific gravity was the ſame with that of the air procured from ſpirit of wine.

In extracting air from ſolid ſubſtances, the ſteam of water was always neceſſary; and thus inflammable air was produced from a great number of different ones. From ſulphur treated in this manner in an earthen tube, inflammable air was obtained of a nature ſimilar to that from oil of vitriol and iron. From arſenic, the produce was one-ſeventh of fixed air; but all the reſt ſtrongly inflammable, with a ſcent ſcarcely diſtinguiſhable from that of phoſphorus. Both theſe experiments, however, were very troubleſome, on account of the volatility of the matters, which ſublimed and choaked up the tubes. From two ounces of the ſcales of iron, or fining cinder, which he has found to be the ſame thing, Dr. Prieſtley obtained 580 ounce-meaſures of air; one-tenth of the firſt part of which was fixed air, but afterwards it was all inflammable. From charcoal expoſed to the red-hot ſteam of water, inflammable air was procured in great quantities. From ninety-four grains of perfect charcoal, that is, prepared with a ſtrong heat ſo as to expel all fixed air from it, and 240 ounces of water, 840 ounce-meaſures of air were obtained, one-fifth part of which was fixed air; and the inflammable part appeared likewiſe, by decompoſition, to have a quantity of fixed air intimately combined with it.

I have obſerved, ſays the doctor, that when ſufficient care is taken to free inflammable air from acid vapour that may be accidentally contained in it, it is not in the ſmalleſt degree affected by a mixture of alkaline air. On the whole I have at preſent no doubt, but that pure inflammable air, though it certainly contains water, does not neceſſarily contain any acid: yet an acid vapour may be eaſily diffuſed through it, and may perhaps in many caſes be obſtinately retained by it, as no kind of air ſeems to be capable of ſo great a variety of impregnations as inflammable air is."

In his analyſis of different kinds of inflammable air, the Doctor obſerves, that the difference moſt commonly perceived is, that ſome of them burn with a lambent flame, ſometimes white, ſometimes yellow, and ſometimes blue; while another kind always burns with an exploſion, making more or leſs of a report when a lighted candle is dipped into a jar filled with it. The inflammable air extracted from metals by means of acids is of this laſt kind; and that from wood, coal, or other inflammable ſubſtances by means of heat, belongs to the former. It has alſo been obſerved, that theſe kinds of inflammable air have different ſpecific gravities; the pureſt, or that which is extracted from iron, &c. being about ten times as light as common air; but ſome of the other kinds not more than twice as light.

Inflammable air, when produced in the drieſt way poſſible, is exceedingly light, but Dr. Prieſtley has found, that by ſtanding on water, a very conſiderable increaſe is made in its ſpecific gravity; ſo that from being ten or twelve times lighter than atmoſpherical air, it ſoon becomes only ſeven times lighter. This great propenſity to unite with water is alſo taken notice of by Mr. Kirwan; who tells us, that the bulk of inflammable air obtained over water with the aſſiſtance of heat towards the end, was one-eighth greater than when produced over mercury; but that the weight of it in the former caſe was only eight or nine times leſs than common air.

There is an aſtoniſhing variety in the different kinds of inflammable air, the cauſe of which is very imperfectly known. The lighteſt, and therefore probably the pureſt kind, ſeems to conſiſt of phlogiſton and water only. But it is probable that oil, and that of different kinds, may be held in ſolution in ſeveral of them, and be the reaſon of their burning with a lambent flame, and alſo of their being ſo readily reſolved into fixed air when they are decompoſed by dephlogiſticated air.

Inflammable air is abſorbed by water in conſiderable quantities, but by the application of heat may be expelled again in equal quantities. By agitation in water Dr. Prieſtley was formerly of opinion that this kind of air might be rendered as good as common air; but this undoubtedly proceeds from the atmoſpherical air tranſmitted by the water, as is the caſe with phlogiſticated air. After a quantity of water, which had abſorbed as much inflammable air as it could, had been ſuffered to ſtand a month, it was expelled by heat, and found to be as ſtrongly inflammable as ever. The water, after the proceſs, depoſited a kind of filmy matter; which the Doctor ſuppoſed to be the earth of the metal that had been employed in producing it.

Plants in general grow tolerably well in inflammable air, and the willow plant has been obſerved to abſorb great quantities of it. Its inflammability is not in the leaſt diminiſhed by the putrefaction of animal ſubſtances, nor does their putrefaction ſeem to be retarded by it. Animals confined in it are killed almoſt as ſoon as in fixed air: but inſects, which can live a conſiderable time in phlogiſticated air, live alſo a conſiderable time in this kind of air: but at laſt they become torpid, and appear to be dead, though they will ſtill recover if removed into the open air. Mr. Cavallo relates, that the Abbé Fontana, having filled a large bladder with inflammable air, began to breathe in it in his preſence: after having made a very violent expiration, in which caſe the effects are moſt powerful. The firſt inſpiration produced a great oppreſſion in his lungs, the ſecond made him look very pale, and the third was ſcarce accompliſhed when he fell on his knees through weakneſs. Birds and ſmall quadrupeds, incloſed in ſmall veſſels of this air died after a very few inſpirations.

The inflammability of air has given occaſion to various projects by different perſons concerning it; ſuch as that of employing it to give light and heat; and lamps have been deſcribed, which may be lighted by the electric ſpark in the night-time. By its means alſo very pretty artificial fires are made, with glaſs tubes bent in various directions, and pierced with a great number of ſmall apertures. The inflammable gas is introduced into theſe tubes, from a bladder filled with that fluid, and fitted with a copper cock. When the bladder is preſſed, the inflammable air, being made to paſs into the tube, iſſues out of all the ſmall apertures, and is ſet on fire by a lighted taper. None of theſe contrivances, however, have ever been applied to any uſe; and the ſcheme of Mr. Volta, who propoſed to ſubſtitute its exploſive force inſtead of gun-powder, is found inſufficient, on account of the weakneſs of the exploſion, except when the two airs are fired in very great quantities, which would be incompatible with the ſmall bulk neceſſary for warlike engines.

DEFINITION VI.

Dr. Prieſtley has the honour of having found out the properties of ſulphurated inflammable air, in the following manner. Having, among others, treated mangane ſe in this manner, by ſtopping one end of the heated tube with a cork before the ſteam was applied, he received forty ounce-meaſures of air, of which one-ſixth was fixed air and the reſt of the ſtandard of 1.7, lambently inflammable. Having then opened the other end of the tube in order to admit the ſteam, air was produced more copiouſly than before. Of 50 ounces of this air, one-ſeventh was fixed, and the reſt, of the ſtandard of 1.8, exploſively inflammable. The laſt portions were very turbid; and the ſcent, eſpecially that of the laſt portion, was very ſulphurous, tinging the water of a very dark colour, by depoſiting in it a quantity of blackiſh water. However, the air itſelf became preſently tranſparent, and had no other appearance than that of any other kind of air. On looking at the jar in about ten minutes after, it was quite black and opaque; ſo that nothing could be ſeen in the inſide of it. On expoſing it to the open air, the colour diſappeared, and a yellow or brown incruſtation was left upon it. The ſame change took place when the veſſel was inverted in water, in order to obſerve the alteration of the air withall; but on examining this air, no ſenſible change was perceived. In ſome caſes, indeed, he thought the air was injured, but it was much leſs ſo than he had expected. After depoſiting the black matter, the air ſtill retained its ſulphurous ſmell, and he did not imagine that it would ever leave it entirely. On trying other ſpecimens of mangane ſe, no air of this kind was obtained; but ſome time after, having occaſion to make a large quantity of inflammable air, he uſed, inſtead of freſh iron, ſome that had been already melted in vitriolic acid air. Diſſolving this with a conſiderable quantity of freſh metal in diluted vitriolic acid, he found that the water in which the air was received became very black, and depoſited more ſediment than had appeared in the experiment with the mangane ſe.

On burning a quantity of this kind of air it appeared to contain ſome vitriolic acid, the balloon being filled with a very denſe white fume, which rendered the water ſenſibly acid to the taſte. On decompoſing it with dephlogiſticated air, however, he found the diminution exactly the ſame as when common inflammable and dephlogiſticated air were uſed; ſo that it appeared to contain neither more or leſs phlogiſton than the other; only there was a ſmall quantity of fixed air produced, which is never the caſe with common inflammable air from vitriolic acid and iron. When the ſulphurated inflammable air is received over mercury, very little black matter is produced; and it is remarkable, that though the black matter collected, when the air is taken through water, ſoon grows yellow upon expoſing it to the air, it is not the caſe with that which remains in the water; it adheres to the evaporating veſſel in form of a black incruſtation, which does not burn blue until it has been digeſted in the nitrous acid, which deprives it of its ſuperfluous phlogiſton, and leaves it both of the colour and ſmell of ſulphur.

DEFINITION VII.

Dr. Prieſtley has the credit of having found out the principles of alkaline air, which in the beginning of his experiments, he procured from common ſpirit of ſal-ammoniac with quicklime, or the materials from which it is made. He did not at that time proſecute the diſcovery farther than by impregnating water with it; by which means he could make a much ſtronger alkaline ſpirit than any to be met with in the ſhops. His method of procuring it was by mixing one part of pounded ſal-ammoniac with three parts of ſlacked lime; and for common experiments the ſame quantity of materials would laſt a conſiderable time.

This kind of air, when pure, is inſtantly fatal to animal life, and extinguiſhes flame; though, when mixed with common atmoſpherical air, it is ſlightly inflammable, and alſo medicinal in faintings and other caſes of debility. A candle dipped into a jar of this air is extinguiſhed; but juſt before the flame goes out, it is enlarged by the addition of another flame of a pale yellow colour, and ſometimes a weak flame ſpreads for a conſiderable way, or even through the whole body of the alkaline air. It is readily abſorbed by water, and diſſolves ice almoſt as faſt as an hot fire. On confining ſome water impregnated with alkaline air in a glaſs tube, and thus expoſing it to a ſtrong heat in a ſand-furnace for ſome days, it was obſerved that a white ſediment or incruſtation was formed on the ſurface. The Doctor remarked, that bits of linen, charcoal, and ſponge, admitted into a quantity of alkaline air, diminiſhed it, and acquired a very pungent ſmell; eſpecially the ſponge, a bit of which, about the ſize of an hazle-nut, abſorbed an ounce meaſure. It is remarkable that copper, which is ſo eaſily corroded by the common volatile alkalis, is not affected by alkaline air. The ſpecific gravity of this kind of air is, by Mr. Kirwan, determined to be to that of common air as 600 to 1000; though, as he juſtly obſerves, this muſt differ very conſiderably according to the quantity of moiſture it contains.

On heating red precipitate in alkaline air, the doctor obſerved that the mercury was revived as in other caſes, and a conſiderable quantity of water was produced. " It has even, ſays he, run down in drops in the inſide of a veſſel which contained five ounce-meaſures of the air; and a conſiderable quantity of dephlogiſticated air was found in the reſiduum."

Dr. Prieſtley in examining the phenomena which attend the converſion of alkaline air into the inflammable kind, was induced to believe that it was occaſioned by heat alone, without the concurrence of light. The effects of the former were firſt perceived on heating ſome ochre of iron in alkaline air; when, though the matter turned black, as in an incipient reduction of the metal, he found a conſiderable increaſe of quantity inſtead of decreaſe in the air, as he had expected; and, on examining the quality of it, he found that it contained no fixed air, but was entirely inflammable. With ſcales of iron a ſimilar enlargement was perceived; but in this way he could never increaſe the quantity to more than double that which had been originally employed, and even after this the whole ſmelled ſtrongly of volatile alkali; the iron had undergone no change.

The doctor now, concluding from theſe experiments that the change of alkaline into inflammable air was produced by this cauſe alone proceeded to repeat the experiment, by heating in the alkaline air bits of dry crucibles, or of earthen retorts, which had been juſt before expoſed to very great heats, ſo that they could not be ſuppoſed to give out any air themſelves, and therefore could only ſerve to communicate a ſtrong heat to the alkaline air; and in theſe experiments the reſult was the ſame as when ochre and iron were made uſe of. The bits of white earthen ware were always turned black; but finding the ſame effect of augmenting the air and giving it an inflammable quality, though he uſed the bit of crucible over and over again, he was thoroughly convinced that the change was effected by heat alone.

In all theſe experiments, however, with a burning-glaſs, as a ſtrong light was alſo concerned, he heated a quantity of alkaline air in a green glaſs retort, receiving in a glaſs tube, filled with water, all the air that could be expelled from it by heat. At firſt it was all abſorbed by the water, being merely alkaline air expelled by the rarefaction; but when the bulb of the retort became red-hot, he found that the bubbles driven out were not wholly abſorbed, and at laſt none of them were ſo. Theſe were altogether inflammable; ſo that no doubt remained of the change being produced by heat alone, without any intervention of light.

It was farther obſerved, that whenever the alkaline air was changed into inflammable by means of bits of retorts or crucibles containing clay, they always became black during the proceſs. He was inclined therefore to ſuppoſe, that ſomething might be depoſited from the air which might attach itſelf to the clay.

The doctor, in ſome former experiments, had obſerved that iron, which had long ruſted in nitrous air, gave out a ſtrong ſmell of volatile alkali. This extraordinary phenomenon, however, was only perceived where the nitrous air and iron had been in contact for a very long time; but he found it was much ſooner produced by making uſe of a weak ſolution of copper; by putting iron into which he obtained that ſpecies of nitrous air called *dephlogiſticated.* A phial containing ſome of this iron, which had been uſed only once for the purpoſe juſt mentioned, having been kept cloſe corked for about two months, was accidentally broken; when ſome pieces of the iron were found covered with a green cruſt, and theſe had a ſtrong ſmell of volatile alkali. On making ſome more experiments on this ſubject, he found that two months ſtanding was requiſite to produce the alkaline ſmell deſired.

DEFINITION VIII.

Nitrous air is plentifully obtained in all caſes where the nitrous acid is combined with phlogiſton: thus, when it is mixed with metals, or animal or vegetable ſubſtances, nitrous air is produced in great quantities; but very ſparingly when treated with metallic calces, earths, or other matters which are ſaid to contain little or no phlogiſton. All the metals, except gold, platina, and regulus of antimony, which are not ſoluble in the pure nitrous acid, yield nitrous air on being treated with it; and even from theſe, when diſſolved in aqua regia, ſome quantity of this air may be obtained.

A diverſity in the ſtrength of the acid will diſcover material differences in the production of this kind of air. For inſtance, if we diſſolve copper in ſtrong nitrous acid, no nitrous air is produced, though the ſame materials will yield air in great quantities, by the mere affuſion of water to dilute the acid. This is very properly explained by Dr. Prieſtley, from the property that the nitrous acid has of attracting phlogiſton, which is evident from what happens in the ſolution of mercury. When ſtrong ſpirit of nitre is poured upon this metal the ſolution ſoon begins, and is very rapid, yet not a ſingle bubble of elaſtic fluid is produced; but in a ſhort time the acid next to the mercury is changed of an orange colour, which is an indication of its having acquired phlogiſton, probably from the nitrous air which is decompoſed the moment it is formed, and before its particles are united into viſible bubbles. The bubbles of air, indeed, break through the coloured acid, but they diſappear the moment they come in contact with the pale coloured acid. As ſoon as the whole quantity of acid has aſſumed the orange colour, nitrous air eſcapes from it in conſiderable quantities; but the mixture of water deprives the acid of its power of decompoſing nitrous air. For the eaſy production of nitrous air from copper and mercury the ſtrong and pale-coloured nitrous acid ought to be diluted with at leaſt two or three parts of water to one of the acid.

No other degree of heat is neceſſary, in common experiments, than that produced by the effervescence itſelf, except mercury be uſed, which requires the application of ſome degree of heat; but when the metal expoſes a very great ſurface to the acid, as is the caſe when the filings of the metal are uſed, the efferveſcence and production of nitrous air are often much quicker than can be conveniently managed.

With reſpect to the properties of nitrous air, it is, by itſelf, equally tranſparent and inviſible with common air, except at its firſt production, when it is ſomewhat coloured, owing to a little ſuperfluous nitrous acid, or to ſome earthy particles which are carried up with it. Its ſmell reſembles that of nitrous acid, or, indeed, is the very ſame; becauſe, in paſſing through the common air to our noſtrils, it is decompoſed, and converted into nitrous acid.

Of all the different airs the nitrous ſeems to be the moſt fatal to animal life of any. Even inſects, which can bear phlogiſticated and inflammable air, generally die the moment they are put into it. Frogs, ſnails, and other animals, which do not reſpire very frequently, die in a few minutes, and generally do not recover even when taken out of this noxious fluid before they are dead.

Nitrous air has various ſingular properties, but the moſt remarkable is its diminution with dephlogiſticated air; by which means it becomes a teſt of the quantity of that kind of air contained in the atmoſphere. With pure dephlogiſticated air the diminution is almoſt to nothing, at the ſame time that ſome quantity of nitrous acid is re-produced by the decompoſition of the nitrous air; but as our atmoſphere is always mixed with a conſiderable quantity of phlogiſticated air, on which nitrous air has no effect, the diminution in this caſe is never ſo conſiderable.

Another very remarkable property of nitrous air is its ſtrong antiſeptic power; inſomuch that animal matters may, by its means, be preſerved for many months without corruption.

The ſpecific gravity of nitrous air, as well as of other kinds, has been aſcertained by Mr. Kirwan. As it corrodes metals, he endeavoured to find its weight by comparing the loſs ſuſtained by the materials which produce it. Thus he found that 14 grains of the materials produced 38.74 inches of nitrous air; and, conſequently, by proper calculation, that the ſpecific gravity of nitrous air is to that of atmoſpheric air as 1195 to 1000.

Dr. Prieſtley made various experiments on nitrous air, ſome of the moſt remarkable of which we ſhall ſtate in his own words. "When nitrous air (ſays he) is decompoſed by iron, or by a mixture of iron and ſulphur, the water, over which the proceſs is conducted, acquires no acidity; but I had ſuppoſed that all the acid was abſorbed by the iron. Having by me a quantity of this iron which had been reduced to perfect ruſt in nitrous air, and which I knew muſt have imbibed more than its weight of this air, I thought that the acid might be obtained from it by diſtillation; but a quantity of this ruſt of iron, diſtilled in an earthen retort, yielded neither nitrous air or nitrous acid, at leaſt in any quantity that could favour the common hypotheſis. I then endeavoured to decompoſe nitrous air by heating iron in it with a burning lens; and in this proceſs I ſucceeded far beyond my expectation: for the air was ſoon diminiſhed in quantity, while the iron became of a darker colour, was ſometimes melted into balls, and gathered conſiderable weight, though it had no appearance of containing any nitrous acid. In the firſt experiment the original quantity of nitrous air was diminiſhed to about one third; and after this it was increaſed."

The Doctor then proceeded to try various experiments on the decompoſition of nitrous air, particularly that of burning Homberg's pyrophorus; but without any ſucceſs, or obtaining the ſmalleſt particle of nitrous acid.

DEFINITION IX.

Dephlogiſticated nitrous air differs from common nitrous air in being able to ſupport flame, though it ſtill continues fatal to animal life. Common nitrous air may be converted into the dephlogiſticated kind by particular proceſſes; though, when zinc is diſſolved in the nitrous acid, if the air be taken at different times, that which comes about the middle, or rather the latter end of the proceſs, will be of this kind; in which it not only ſupports the burning of a candle, but the flame is enlarged (ſometimes to four or five times its original bulk) by the addition of a weaker and bluiſh flame round the former; and this burning is ſometimes accompanied with a crackling noiſe, as if the candle was burning in dephlogiſticated air. It may alſo be obtained in ſome part of the proceſs of procuring nitrous air from iron, though with this metal the ſucceſs is uncertain; but tin yields a conſiderable quantity of it.

By expoſing iron to nitrous air, it may be ſo far dephlogiſticated as to admit a candle to burn in it. Dr. Prieſtley filled an eight ounce phial with nails, and then with mercury; and diſplacing the mercury with nitrous air, left the phial inverted in a quantity of the ſame fluid. Two months after the nitrous air was found to be changed in ſuch a manner as to admit a candle to burn in it with its natural flame; and by continuing ſtill longer in contact with the iron, a candle would burn in it with an enlarged flame. Theſe changes, however, are very irregular, ſo that they ſeldom produce the like effects with the regularity that might be expected. Dr. Prieſtley once found, that by the contact of iron in quickſilver, it was ſo changed as to be fired with an exploſion like a weak inflammable air; whilſt another quantity of nitrous air, which had been treated in like manner for about the ſame length of time, only admitted a candle to burn in it with an enlarged flame.

The diſſolving turnings of iron in a dilute ſolution of copper in nitrous acid (the ſame that remains after the production of nitrous air) mixing it again with an equal quantity of water, produces this kind of air. Without this precaution the Doctor tells us, that though the iron will at firſt be acted upon very ſlowly, yet the mixture will at length grow ſo hot as actually to boil, and the proceſs will be exceedingly troubleſome: however, it will be neceſſary, previous to any attempt to diſſolve the iron, to heat the ſolution of copper, in order to expel all the nitrous air and ſuperfluous nitrous acid, otherwiſe a quantity of common nitrous air will be produced.

Air of this kind is abſorbed by water almoſt as readily as fixed air, and in conſiderable quantity; the liquid taking up about one-half its bulk of air. After being thus ſaturated, the nitrous air may be expelled pure by heat, and is eaſily received in veſſels containing mercury. It was likewiſe obſerved, that as this kind of air much reſembles fixed air in its properties of being imbibed by water, and expelled again by heat, it reſembles it alſo in this farther property, that all the air which has been actually incorporated with the water will not be imbibed by water again. But the proportion of this part is three or four times greater than the correſponding part of fixed air; it is alſo conſiderably more phlogiſticated. Water impregnated with it very ſoon parts with it again on being expoſed to the atmoſphere.

DEFINITION X.

Acid airs are as follow. 1. *Vitriolic acid Air* is always a combination of vitriolic acid with phlogiſton, conſequently may be procured from any mixture of that acid in its highly concentrated ſtate with phlogiſtic matters. Hence it is obtained from all the metals, gold and platina excepted, on boiling them with ſtrong oil of vitriol. It is alſo procurable from the ſame acid rendered black by any phlogiſtic matter. No greater heat is required to expel this kind of air than that produced by the flame of a candle. It is the heavieſt of all aerial fluids, next to fluor acid air, being to common air as 2265 to 1000.

2. *Nitrous acid air* is procured by heating the ſtrong ſpirit of nitre in a phial, and then receiving the vapour in glaſs veſſels filled with quickſilver. It is, however, extremely difficult, or rather impoſſible, to preſerve it for a length of time by means of any fluid hitherto known. Water abſorbs it immediately, and quickſilver is corroded, and produces nitrous air.

The moſt remarkable property of this vapour is, that it aſſumes a red colour by the mere circumſtance of heat.

3. *Marine acid air*. This is procured by filling a phial, fitted with a glaſs tube and ſtopper, with common ſalt, and then pouring a ſmall quantity of oil of vitriol upon it; which, by the aſſiſtance of heat, will diſengage the acid principle, or the marine acid air, from the ſalt. This air is fatal to all manner of inſects.

4. *Fluor acid air* was diſcovered by Mr. Scheele, who obtained it by diſtilling the ſpar called fluor with vitriolic acid. Its moſt remarkable property is the great attraction it has for ſiliceous earth; ſo that it even corrodes and makes holes in the retorts in which it is diſtilled.

5. *Vegetable acid air* may be produced by heat alone. The concentrated vegetable acid emits a permanently elaſtic and aerial fluid. This has the properties of the acid of vinegar; but, like it, is weaker than the reſt of the mineral acid airs, though it agrees with them in its general characters.

DEFINITION XI.

Hepatic air was firſt particularly taken notice of by Mr. Bergman, who obtained it from an ore of zinc called *Pſeudogalena nigra Dannemorenſis*, and which was found to contain 29 parts of ſulphur, one of regulus of arſenic, ſix of water, ſix of lead, nine of iron, 45 of zinc, and four of ſiliceous earth. The hepatic air was produced but in ſmall quantity by pouring oil of vitriol on this mineral; ſpirit of ſalt produced it in much larger quantity; but nitrous acid produced only nitrous air. The moſt proper method of obtaining this air is by pouring marine acid on hepar ſulphuris, which extricates it in vaſt quantities. It is ſaid alſo to be ſometimes produced naturally from putrefying matters. It is the characteriſtic of all livers of ſulphur, whether they be made with alkalis or earths. The ſmell of the pure gas is intolerable; and the vapour has a diſagreeable effect on many metallic ſubſtances, particularly ſilver, lead, copper, &c. deſtroying their colour, and rendering them quite black. It is ſuddenly fatal to animal life, renders ſyrup of violets green, and is inflammable, burning with a very light blue flame.

Its ſpecific gravity, compared with that of atmoſpherical air, is as 1106 to 1000. It combines readily with water, and gives the ſmell to the ſulphurous medicinal waters.

DEFINITION XII.

Atmoſpherical air conſiſts of the two component parts of our atmoſphere, viz. dephlogiſticated and phlogiſticated air, which have been fully treated of under their reſpective definitions, ſo that little remains to be ſaid in this place, excepting to determine the proportion in which they are uſually met with in the common air. The only regular ſet of experiments which have been made on this ſubject are thoſe of Mr. Scheele. He conſtructed an eudiometer, conſiſting of a glaſs receiver, which could contain 34 ounces of water, and a glaſs cup containing a mixture of one pound of iron-filings, and an equal weight of flowers of ſulphur moiſtened; which cup ſtanding upon a glaſs ſupporter, was inſerted in the former receiver, which, when this was in it, could contain 33 ounces of water. To the outſide of the glaſs tube or receiver, was affixed a ſlip of paper, to the height of a third of the tube, containing 11 diviſions, each correſponding to one ounce of water. This paper was varniſhed over with oil varniſh, to prevent its being ſpoiled by water. The whole then was placed in water, which gradually roſe as the air was diminiſhed. This mixture would ſerve four times before the power of diminiſhing air was loſt. He carefully compared the height of the air therein with the barometer and thermometer, both before and after the experiment; in eight hours the experiment was completed. With this inſtrument he examined the goodneſs of the common air in Stockholm every day for a whole year, and found the diminution never to exceed $\frac{10}{33}$, nor to fall ſhort of $\frac{8}{33}$; ſo that upon a medium it may be eſtimated at $\frac{9}{33}$.

Application of the foregoing DEFINITIONS.

Fixed Air, or Aërial Acid. The artificial methods of producing this are principally three, viz. by fermentation, by heat, and by acids.

1. *By Fermentation.* When vegetable or animal ſubſtances, eſpecially the former, are fermented, they yield a great quantity of fixed air. In breweries, on the ſurface of the fermenting liquor, there is always a ſtratum of fixed air reaching as high as the edge of the vats; ſo that if theſe veſſels are deep, and the fermenting liquor much below their edges, the above-mentioned ſtratum may be ſome feet in thickneſs. The ſame phenomenon is obſervable in the fermentation of wines in general; and it is owing to the production and elaſticity of fixed air, that fermenting liquors, when put into cloſe veſſels, often burſt them with great violence. The caſe is the ſame whatever ſubſtance it is that undergoes the vinous fermentation, though the quantity of fixed air produced is not the ſame in all ſubſtances, nor even in the ſame ſubſtance at different times. From 42 cubic inches of beer Dr. Hales obtained 639 cubic inches of air in 13 days. From a quantity of ſugar undergoing the vinous fermentation, Mr. Cavendiſh obtained ſo much fixed air, that out of 100 parts of the former, 57 appeared to have been volatilized and converted into fixed air.

But though a vaſt quantity of fixed air eſcapes during this proceſs of fermentation, a very conſiderable portion ſtill remains united with the fermented liquor, and to this it owes all its briſkneſs and agreeable pungent acidulous taſte; for when the fixed air is totally evaporated, the liquor becomes entirely vapid and flat. Hence alſo we are furniſhed with a method of reſtoring the briſkneſs to theſe liquors after they have loſt it in conſequence of being expoſed to the atmoſphere, viz. by impregnating them again with fixed air, either naturally or artificially produced.

Fixed air is likewiſe produced, though in no great quantity, by putrefaction. In this caſe, however, a great part of the elaſtic fluid conſiſts of inflammable and phlogiſticated air, and the fixed air itſelf ſeems to be intimately connected with a putrid offenſive effluvium.

2. *By Heat.* In every combuſtion, except that of ſulphur or of metals, a quantity of fixed air is generated. This may be obſerved by fixing a lighted candle in an inverted receiver over a baſon of lime-water, for a precipitation of the lime will preſently enſue; and the ſame precipitation will always happen, whether a candle, a burning piece of wood, or, in ſhort, any other combuſtible ſubſtance, except ſulphur or metals, be made uſe of.

Moſt minerals contain fixed air, which may be extracted to a certain degree by means of heat. Mr. Krenger, diſtilling a greeniſh fuſible ſpar, which was luminous in the dark, obtained from it ſome permanently elaſtic fluid, which, like fixed air, cryſtallized a ſolution of fixed alkali. Mr. Fontana, in his analyſis of the malachite, finds that that mineral contains a vaſt quantity of fixed air, as pure as that which is extracted from chalk by means of vitriolic acid.

From almoſt every metallic ore and earthy mineral, ſome fixed air may be obtained, as well as from chalk, lime-ſtone, marble, marine ſhells, fixed and volatile alkali, and from magneſia alba, by means of a violent heat.

3. *By Acids.* Calcareous ſubſtances in general produce abundance of fixed air when acted upon by any acid, only the ſtrongeſt acids will expel from them more fixed air than the weakeſt; and it happens to be peculiarly advantageous for thoſe who want to produce a great quantity of fixed air, that the vitriolic acid is both the cheapeſt and ſtrongeſt acid, and, upon the whole, the fitteſt for this purpoſe.

To produce Inflammable Air.

The proceſs for making this ſort of gas is the ſame as that for making fixed air; except that iron-filings, or groſsly powdered zinc, muſt be uſed inſtead of chalk; to which muſt be added ſome oil of vitriol and water.

Inſtead of the filings of iron, ſmall nails, or ſmall bits of iron-wire, anſwer equally as well.

The inflammable elaſtic fluid produced by this mixture has a diſpleaſing ſmell, even when mixed with a very large quantity of common air; ſo that if any conſiderable quantity of it comes out of the bottle, before the cork with the bent tube be applied to it, &c. its ſmell may be diſcovered all over the room in which the experiment is made.

Having filled a bottle with this elaſtic fluid, ſtop the mouth of it with your thumb, or any ſtopper, and then bring it near the flame of a candle; and when the mouth of the bottle is very near it, remove the ſtopper, and the elaſtic fluid contained in the bottle will be immediately inflamed; and if the capacity of the bottle is nearly equal to four ounce-meaſures, it will continue burning quietly for about half a minute, the flame gradually deſcending lower and lower, as far as about the middle of the bottle, in proportion as the inflammable gas is conſumed.

It is evident from this experiment, that inflammable air follows the general rule of all other combuſtible ſubſtances, namely, that of burning only when in contact with common air: thus the flame of this gas, whilſt burning, is obſervable only on that ſurface of it which is contiguous to the common air; ſo that if the bottle be cloſed, the flame is put out immediately, becauſe the air is intercepted from it. But if the inflammable air were put in ſuch a ſituation as to expoſe a very great ſurface to the common air, it is plain, that by this means its combuſtion would be accelerated, ſo as to let it burn inſtantly, and go off with an exploſion, cauſed by the ſudden rarefaction of the air. In fact, this effect may be eaſily obſerved in the following manner: When the bottle is to be inverted in order to let it be filled with the inflammable gas, inſtead of filling it entirely with water, let half of it remain filled with common air; then invert it, and let the other half, which is now filled with water, be filled with inflammable air after the uſual manner; and when the bottle is full, remove it to the flame of the candle, by which means the inflammable air takes fire; but now it explodes all at once with a large flame and a conſiderable report, ſometimes breaking the bottle in which it is contained. In this caſe, the bottle being filled with equal parts of inflammable and common air, theſe two elaſtic fluids were mixed together, ſo that almoſt every particle of the one touched every particle of the other, and hence the ſudden combuſtion was occaſioned. The force of this exploſion is ſo very conſiderable, that ſome piſtols have been contrived, which are charged with a mixture of air and inflammable gas, and being fired by means of an electric ſpark, are capable to drive a leaden bullet with great violence. Sometimes thoſe piſtols are made of glaſs, but in this caſe they are not charged with a bullet, and it is very diverting to ſhow that piſtols are charged and explode by the combuſtion of an inviſible ſubſtance.

When a ſlender pipe is tied to the neck of a bladder, and the bladder is filled with inflammable air, after the manner deſcribed in the preceding experiment, viz. when the bladder was required to be filled with fixed air, two very pleaſing experiments may be performed with it. Firſt, the inflammable gas may be inflamed by applying the flame of the candle to the extremity of the pipe; and ſqueezing at the ſame time the bladder, a ſtream of fire will be formed in the air, which will laſt as long as the bladder contains any inflammable air; for this gas coming out of the pipe with violence, will continue inflamed for a conſiderable way in the air. Secondly, the extremity of the pipe may be dipped into a ſolution of ſoap, then removing it from the ſolution, and ſqueezing the bladder very gently, a ball of ſoap-water may be formed, including inflammable air: which ball, on account of the inflammable gas being much lighter than common air, as ſoon as it is detached from the pipe will aſcend upwards, and will break by daſhing againſt the ceiling, contrary to thoſe commonly made by children, which in ſtill air go downwards. Whilſt the ball is aſcending, if the flame of the candle be approached to it, the film of ſoap-water will be inſtantly broke, and the inflammable air will take fire; thus a flame may be ſhown to be ſeemingly produced from a ſoap-ball.

In order to obtain the greateſt quantity of inflammable air from iron or zinc, the vitriolic acid muſt be diluted with much water, as about one part of ſtrong oil of vitriol to five or ſix parts of water. Dr. Prieſtley found, that 11 grains of iron yielded 8¼ ounce-meaſures of inflammable air. According to Mr. Cavendiſh, one ounce of zinc, diſſolved either in the vitriolic or marine acid, yields a quantity of inflammable air equal to the bulk of 356 ounces of water; one ounce of iron, diſſolved by means of vitriolic acid, yields a quantity of inflammable air equal to the bulk of 412 ounces of water; and one ounce of tin yields half as much inflammable air as iron does.

By means of nitrous acid, inflammable air may be obtained from various ſubſtances containing phlogiſton; but it is always mixed with nitrous air, and ſometimes alſo with fixed and common or phlogiſticated air. If two parts of ſpirit of wine, mixed with one part of nitrous acid, are put into a phial with a ground-ſtopple and tube, and the flame of a candle be applied to it, ſo as to heat it gradually, the inflammable air will be produced very readily; the inflammability of which is, however, not very permanent, for by a little waſhing in water it may be annihilated. In the ſolution of moſt ſubſtances in nitrous acid, it generally happens, that the elaſtic fluid, which is obtained towards the latter end of the proceſs, poſſeſſes the property of being inflammable: thus iron, diſſolved in nitrous acid, yields nitrous air; but when the nitrous air ceaſes to be produced, if the heat of a candle be applied to the ſolution, more elaſtic fluid will be produced which is inflammable. The nitrous acid when mixed with iron-filings in a very diluted ſtate, gives, by the aſſiſtance of a moderate degree of heat, a mixture of different airs, partly fixed, partly common, and partly phlogiſticated.

To produce Nitrous Air.

This permanently elaſtic fluid is never found naturally, like fixed or inflammable air, but is entirely artificial. Either ſilver, copper, braſs, iron, mercury, biſmuth, or nickel, when mixed with nitrous acid, yield nitrous air in great quantities. Some of them, eſpecially mercury, require the aid of heat in order to produce the elaſtic fluid; the flame of a candle applied to the phial is ſufficient; but others, eſpecially copper and iron, do not want the application of any heat. Gold, platina, and the regulus of antimony, when put in aqua regia, yield nitrous air pretty readily.

Among the ſemi-metals, zinc gives the weakeſt nitrous air, when diſſolved in nitrous acid. The elaſtic fluid produced from it is moſtly phlogiſticated air. From four pennyweights and 17 grains of zinc, diſſolved in ſpirit of nitre diluted with an equal quantity of water, Dr. Prieſtley obtained about 12 ounce-meaſures of very weak nitrous air. It occaſioned a very ſlight effervefcence when mixed with common air. The Doctor obtained nitrous air even from ſome flowers of zinc.

Nitrous air is obtained from various kinds of metals, all of which materially differ in their produce. Braſs yields nitrous air of a more uniform nature than iron: copper is ſuperior to braſs; but pure mercury is ſtill ſuperior to copper: and indeed this is the metal which, conſidering its nature, uniformity of ſubſtance, and eaſy ſolution, is upon the whole the moſt uſeful for this purpoſe.

In order to obtain nitrous air from the ſolution of animal and vegetable ſubſtances in nitrous acid, often ſome degree of heat muſt be applied. The acid alſo ſometimes muſt be very concentrated, and in other caſes it muſt be diluted; but it is hardly worth while, or practicable, to determine with exactneſs all thoſe particular caſes.

To produce Dephlogiſticated Air.

This is no other than exceeding pure atmoſpherical air, entirely free from thoſe heterogeneous vapours which contaminate the air we commonly breathe. The eaſieſt method of procuring this air is to put ſome red-lead into the bottle, together with ſome good ſtrong oil of vitriol, but without any water. Let the red-lead fill about a quarter of the bottle, and the vitriolic acid be about the ſame quantity or very little leſs; then apply the bent tube to the bottle. But it muſt be remarked, that without heat this mixture of red-lead and vitriolic acid will not give any dephlogiſticated air, or it yields an inconſiderable quantity of it; for which reaſon the flame of a candle, that of a wax taper is ſufficient, muſt be applied under the bottom of the bottle; which for this purpoſe muſt be rather thin, otherwiſe it will be eaſily cracked. In this manner the red-lead will yield a good quantity of elaſtic fluid, the greateſt part of which is dephlogiſticated air; but not the whole quantity of it, for a large portion of fixed air comes out with it. In order to ſeparate the fixed from the dephlogiſticated air, the inverted bottle, when filled with the compound of both, as it is emitted from the red-lead, muſt be ſhook in the baſin for impregnating water with fixed air; by which means the water will abſorb the whole quantity of fixed air, and leave the dephlogiſticated air by itſelf.

It appears, from every experiment, that dephlogiſticated air, if it could be readily obtained, and at a cheap rate, would be a moſt valuable manufacture. The heat communicated by means of it to burning fuel is incredible.

It has been found by experience, that animals will live much longer in this kind of air than in an equal quantity of common air; whence it is ſuppoſed that the breathing of it muſt be much more healthy, and contribute to longevity much more than the common atmoſphere. Nay, there are not wanting ſome who attribute the longevity of the Antediluvians to the great purity of the atmoſphere at that time; the whole maſs being afterwards tainted by the deluge, in ſuch a manner that it could never regain its former purity and ſalubrity. But all this as yet is mere conjecture; and excepting the ſingle fact, that animals live much longer in a quantity of dephlogiſticated than of common air, there is no evidence that the former contributes more to longevity than the latter. Dr. Prieſtley even throws out a conjecture, that the uſe of dephlogiſticated air might, perhaps, wear out the ſyſtem much ſooner than common air, in the ſame manner as it conſumes fuel much faſter than common air. The great quantity, however, even of the pureſt air, which is requiſite to ſupport animal life, and the expence and trouble of the moſt ready methods of procuring it, have hitherto prevented any fair trial from being made. Yet philoſophers, conſidering the probability there is of this kind of air being ſalutary in many diſeaſes, have beſtowed ſome pains in attempting to find out methods of procuring it eaſily and in large quantities.

To procure Vitriolic Acid Air.

This conſiſts of the vitriolic acid, united with ſome phlogiſton, which volatilizes and renders it capable of aſſuming the form of a permanently elaſtic fluid. To obtain it, ſome ſtrong concentrated vitriolic acid muſt be put into the uſual bottle, together with ſome ſubſtance capable of furniſhing phlogiſton. Olive oil anſwers very well. The oil of vitriol ſhould be about three or four times as much as the ſweet oil, and both together ſhould fill about one-third or half the bottle. A gentle degree of heat is then required, in order to let theſe materials yield any elaſtic fluid; which may be done by applying the flame of a wax taper, as directed for the production of dephlogiſticated air.

To procure Marine Acid Air.

This is no other than the marine acid itſelf, and which, without any addition, becomes a permanently elaſtic fluid. Put ſome ſea ſalt, or common kitchen ſalt, into the uſual bottle in which the materials for producing elaſtic fluids are generally put, ſo as to fill about a fourth part of it, and upon this ſalt pour a ſmall quantity of good concentrated vitriolic acid; then apply the bent tube to the bottle, and introduce it through the quickſilver into the receiver filled with and inverted in quickſilver after the uſual method, and the elaſtic fluid is copiouſly produced.

To procure Nitrous Acid Air.

This may be obtained from heated nitrous acid, the vapour of which acquires a permanent elaſticity, and it has been found to remain uncondenſed into a viſible fluid by any cold to which it has been hitherto expoſed. The great difficulty is to find a fluid capable of confining this acid air; becauſe it is eaſily and abundantly abſorbed by water, which is one of its properties by which it differs from nitrous air. It acts upon quickſilver, and alſo upon oils: hence its examination cannot be made but very imperfectly; for ſubſtances muſt be expoſed to it, or mixed with it, whilſt it is actually changing its nature by acting on the mercury or other fluid that confines it.—*The Engraver has referred the Plates of* Experiments on Air *to the Syſtem of* Aerology, *but as they will come more conſiſtently under* Pneumatics, *we refer our Readers to the deſcriptions of thoſe Plates under that Syſtem.*

AEROMANCY, a ſpecies of divination performed by means of air, wind, &c.

AEROMELI, honey. The word is alſo uſed for manna.

AEROMETRY, a term formerly uſed for the ſcience of meaſuring the air; but has long ſince been generally called Pneumatics.

AERONAUT, a perſon who attends and guides an air balloon.

AERONAUTICA, from αηρ and ναυτικος, derived from ναυς, ſhip: the art of ſailing in a veſſel, or machine, through the atmoſphere, ſuſtained as a ſhip in the ſea.

AEROPHYLACEA, a term uſed by naturaliſts for certain receptacles of air, which have been ſuppoſed to exiſt in the earth. And, according to Kircher, theſe caverns generate the various ſpecies of the mineral kingdom of nature.

AEROSIS denotes the attenuating and converting the blood into aura, for the ſupport of vital ſpirits and the animal flame of life, uſually termed natural vigour.

AEROSTATICA implies that branch of Pneumatics which treats of the weight, preſſure, and balance of the atmoſphere.

A NEW SYSTEM of AEROSTATION.

AEROSTATION, in the modern acceptation of the word, implies aerial navigation, or the art of navigating a machine, called a balloon, through the atmoſphere.

The name of this aeroſtatic vehicle is derived from the globular figure of its conſtruction and contents, being uſually known by the term Air Balloon.

As Aeroſtation has engaged the attention of almoſt all ranks of people in Europe, I ſhall commence its hiſtory from the æra in which the invention of ſuch celebrity took its riſe.

In the year 1782 Meſſrs. Stephen and John Montgolfier, paper-makers of Annonay in France, made the firſt experiment at Avignon, by filling a ſilk bag of a parallelopiped ſhape with the ſmoak of burnt paper, which roſe to the height of 70 feet. But what is moſt extraordinary, thoſe gentlemen took into conſideration the idea of the aſcenſion of ſmoak as rarified air, capable of carrying a covering with it to its congenial region in the atmoſphere, thereby aſſuring themſelves that it muſt aſcend until the confined air, or rather ſmoak, ſhould become condenſed.

From this aſſurance an experiment, on a more enlarged ſcale, was projected; and a new machine, containing about 650 cubic feet, was made, which broke the cords that confined it, and roſe to the height of about 600 feet. Another of 35 feet in diameter roſe about 1000 feet high, and fell to the ground three quarters of a mile from the place where it aſcended.

A public exhibition was next made on the 5th of June 1783, at Annonay, where a vaſt number of ſpectators aſſembled. An immenſe bag of linen, lined with paper, and containing upwards of 23,000 cubic feet, was found to have a power of lifting about 500 pounds, including its own weight. The operation was begun by burning chopped ſtraw and wool under the aperture of the machine, which immediately began to ſwell; and after being ſet at liberty aſcended into the atmoſphere. In ten minutes it had aſcended 6000 feet; and when its force was exhauſted, it fell to the ground at the diſtance of 7668 feet from the place from whence it ſet out.

Some time after this experiment had been made, one of the brothers arrived at Paris, where he was invited by the Academy of Sciences to repeat his experiments at their expence. In conſequence of this invitation he conſtructed, in a garden in the Fauxbourg of St. Germain, a large balloon of an elleptical form. In a preliminary experiment this machine lifted up from the ground eight perſons who held it, and would have carried them all off if more had not quickly come to their aſſiſtance. Next day the experiment was repeated in preſence of the members of the academy; the machine was filled by the combuſtion of 50 pounds of ſtraw made up in ſmall bundles, upon which about 12 pounds of chopped wool were thrown at intervals. The uſual ſucceſs attended this exhibition: the machine ſoon ſwelled; endeavoured to aſcend; and immediately after ſuſtained itſelf in the air, together with the charge of between 4 and 500 pounds weight. It was evident that it would have aſcended to a great height; but as it was deſigned to repeat the experiment before the king and royal family at Verſailles, the cords by which it was tied down were not cut. But in conſequence of a violent rain and wind which happened at this time, the machine was ſo far damaged, that it became neceſſary to prepare a new one for the time that it had been determined to honour the experiment with the royal preſence; and ſuch expedition was uſed, that this vaſt machine, of near 60 feet in height and 43 in diameter, was made, painted with water-colours both within and without, and finely decorated, in no more than four days and four nights. With this machine was ſent a wicker cage, containing a ſheep, a cock, and a duck, which were the firſt animals ever ſent through the atmoſphere. The full ſucceſs of the experiment was prevented by a violent guſt of wind which tore the cloth in two places near the top before it aſcended: however, it roſe to the height of 1440 feet; and, after remaining in the air about eight minutes, fell to the ground at the diſtance of 10,200 feet from the place of its ſetting out. The animals contained in it did not receive the leaſt injury.

From the great power of theſe aeroſtatic machines, and their very gradual deſcent in falling to the ground, it was reaſonably ſuppoſed that they were capable of conveying people through the air with all imaginable ſafety; and this was further confirmed by the experiment already mentioned.

Encouraged by the ſucceſs of theſe experiments, M. Montgolfier propoſed to make a new aeroſtatic machine of a firmer and better conſtruction than the former; and M. Pilatre de Rozier offered himſelf to be the firſt aerial adventurer.

This new machine was conſtructed in a garden in the Fauxbourg of St. Antoine. It was of an oval ſhape, about 48 feet in diameter and 74 in height; elegantly painted on the outſide with the ſigns of the zodiac, cyphers of the king's name, and other ornaments. A proper gallery, grate, &c. were appended; ſo that it was eaſy for the perſon who aſcended to ſupply the fire with fuel, and thus keep up the machine as long as he pleaſed. The weight of the whole apparatus was upwards of 1600 pounds.

The experiment was performed on the 15th of October 1783. M. Pilatre having placed himſelf in the gallery, the machine was inflated, and permitted to aſcend to the height of 84 feet, where he kept it afloat for about four minutes and a half; after which it deſcended very gently: and ſuch was its tendency to aſcend, that it rebounded to a conſiderable height after touching the ground.

Two days after, he repeated the experiment with the ſame ſucceſs as before; but the wind being ſtrong, the machine did not ſuſtain itſelf ſo well as formerly. However, on repeating the experiment in calmer weather, he aſcended to the height of 210 feet. His next aſcent was 262 feet; and in the deſcent a guſt of wind having blown the machine over ſome large trees of an adjoining garden, M. Pilatre ſuddenly extricated himſelf from ſo dangerous a ſituation, by throwing ſome ſtraw and chopped wool on the fire, which raiſed him at once to a ſufficient height. On deſcending again, he once more raiſed himſelf to a proper height by throwing ſtraw on the fire. Some time after he aſcended in company with M. Girond de Villette to the height of 330 feet; hovering over Paris at leaſt nine minutes in ſight of all the inhabitants, the machine, during the time, keeping quite ſtationary.

From theſe experiments it was evident, that the aeroſtatic machines might be raiſed or lowered at the pleaſure of the perſons who aſcended: they had likewiſe diſcovered, that keeping them faſt with ropes was no advantage; but, on the contrary, that this was attended with inconvenience and hazard.

On the 21ſt of November 1783 M. Pilatre determined to undertake an aerial voyage in which the machine ſhould be ſet at full liberty. Every thing being got in readineſs, the balloon was filled in a few minutes; and M. Pilatre placed himſelf in the gallery, counterpoiſed by the Marquis d'Arlandes, who occupied the other ſide. It was intended to make ſome preliminary experiments on the aſcending power of the machine: but the violence of the wind prevented this from being done, and even damaged the balloon eſſentially; ſo that it would have been entirely deſtroyed had not timely aſſiſtance been given. The extraordinary exertions of the workmen, however, repaired it again in two hours, and the adventurers ſet out. They met with no inconvenience during their voyage, which laſted about 25 minutes; during which time they had paſſed over a ſpace of above five miles. From the account given by the Marquis d'Arlandes, it appeared that they met with ſeveral different currents of air, the effect of which was, to give a very ſenſible ſhock to the machine, and the direction of the motion ſeemed to be from the upper part downwards. It appeared alſo that they were in ſome danger of having the balloon burnt altogether; as the Marquis obſerved ſeveral round holes made by the fire in the lower part of it, which alarmed him conſiderably, and, indeed, not without reaſon. However, the progreſs of the fire was eaſily ſtopped by the application of a wet ſponge, and, in a ſhort time, all appearance of danger ceaſed.

This voyage of M. Pilatre and the Marquis d'Arlandes may be ſaid to conclude the hiſtory of thoſe aeroſtatic machines which are elevated by means of fire; for though many other attempts have been made upon the ſame principle, moſt of them have either proved unſucceſsful or of little conſequence. They have therefore given place to the other kind, filled with inflammable air; which, by reaſon of its ſmaller ſpecific gravity, is both more manageable, and capable of performing voyages of greater length, as it does not require to be ſupplied with fuel like the others. This was invented a very ſhort time after the diſcovery made by M. Montgolfier. This gentleman had, indeed, deſigned to keep his method in ſome degree a ſecret from the world; but as it could not be concealed, that a bag filled with any kind of fluid lighter than the common atmoſphere would riſe in it, inflammable air was naturally thought of as a proper ſuccedanium for the rarefied air of M. Montgolfier.

The firſt experiment was made by two brothers named Roberts, and M. Charles, a profeſſor of experimental philoſophy. The bag which contained the gas was compoſed of luteſtring, varniſhed over with a ſolution of the elaſtic gum called *caoutchouc*; and that with which they made their firſt eſſay was only about 13 Engliſh feet in diameter. Many difficulties occurred in filling it with the inflammable air, chiefly owing to their ignorance of the proper apparatus; inſomuch, that, after a whole day's labour from nine in the morning, they had got the balloon only one third part full. Next morning they were ſurpriſed to find that it had fully inflated of itſelf during the night: but, upon enquiry, it was found, that they had inadvertently left open a ſtop-cock connected with the balloon, by which the common air gaining acceſs, had mixed itſelf with the inflammable air; forming a compound ſtill lighter than the common atmoſphere, but not ſufficiently light to anſwer the purpoſes of aeroſtation. Thus they were obliged to renew their operation; and, by ſix o'clock in the evening, of next day, they found the machine conſiderably lighter than the common air; and, in an hour after, it made a ſtrong effort to aſcend. The public exhibition, however, had been announced only for the third day after; ſo that the balloon was allowed to remain in an inflated ſtate for a whole day; during which they found it had loſt a power of aſcent equal to about three pounds, being one ſeventh part of the whole. When it was ſet at liberty, after having been well filled with inflammable air, it was 35 pounds lighter than an equal bulk of common air. It remained in the atmoſphere only three quarters of an hour, during which it had traverſed 15 miles. It deſcended very ſuddenly, which was ſuppoſed to have been owing to a rupture that had taken place in the balloon.

The ſucceſs of this experiment, and the aerial voyage made by Meſſrs. Rozier and Arlandes, naturally ſuggeſted the idea of undertaking ſomething of the ſame kind with a balloon filled with inflammable air. The machine uſed on this occaſion was formed of gores of ſilk, covered over with a varniſh made of *caoutchouc*, of a ſpherical figure, and meaſuring 27½ feet in diameter. A net was ſpread over the upper hemiſphere, and faſtened to an hoop which paſſed round the middle of the balloon. To this a ſort of car, or rather boat, was ſuſpended by ropes, in ſuch a manner as to hang a few feet below the lower part of the balloon; and, in order to prevent the burſting of the machine, a valve was placed in it; by opening of which ſome of the inflammable air might be occaſionally let out. A long ſilken pipe communicated with the balloon, by means of which it was filled. The boat was made of baſket-work, covered with painted linen, and beautifully ornamented; being 8 feet long, 4 broad, and 3½ deep; its weight 130 pounds. At this time, however, as at the former, they met with great difficulties in filling the machine with inflammable air, owing to their ignorance of the moſt proper apparatus. But at laſt, all obſtacles being removed, the two adventurers took their ſeats at three quarters after one in the afternoon of the firſt of December 1783. Perſons ſkilled in mathematics were conveniently ſtationed with proper inſtruments to calculate the height, velocity, &c. of the balloon. The weight of the whole apparatus, including that of the two adventurers, was found to be 604¼ pounds, and the power of aſcent when they ſet out was 20 pounds; ſo that the whole difference betwixt the weight of this balloon and an equal bulk of common air was 624 pounds. But the weight of common atmoſphere diſplaced by the inflammable gas was calculated to be 771 pounds, ſo that there remains 147 for the weight of the latter; and this calculation makes it only 5¼ times lighter than common air.

At the time the balloon left the ground the thermometer ſtood at 9° of Fahrenheit's ſcale, and the quickſilver in the barometer at 30.18 inches; and, by means of the power of aſcent with which they left the ground, the balloon roſe till the mercury fell to 27 inches, from which they calculated their height to be about 600 yards. By throwing out ballaſt occaſionally as they found the machine deſcending by the eſcape of ſome of the inflammable air, they found it practicable to keep at pretty near the ſame diſtance from the earth during the reſt of their voyage; the quickſilver fluctuating between 27 and 27.65 inches, and the thermometer between 53° and 57°, the whole time. They continued in the air for the ſpace of an hour and three quarters, when they alighted at the diſtance of 27 miles from Paris; having ſuffered no inconvenience during their voyage, nor experienced any contrary currents of air, as had been felt by Meſſrs. Pilatre and Arlandes. As the balloon ſtill retained a great quantity of inflammable gas, Mr. Charles determined to take another voyage by himſelf. Mr. Robert accordingly got out of the boat, which was thus lightened by 130 pounds, and of conſequence the aeroſtatic machine now had nearly as much power of aſcent. Thus he was carried up with ſuch velocity, that in twenty minutes he was almoſt 9000 feet high, and entirely out of ſight of terreſtrial objects. At the moment of his parting with the ground the globe had been rather flaccid; but it ſoon began to ſwell, and the inflammable air eſcaped from it in great quantities through the ſilken tube. He alſo frequently drew the valve that it might be the more freely emitted, and the balloon effectually prevented from burſting. The inflammable gas being conſiderably warmer than the external air, diffuſed itſelf all round, and was felt like a warm atmoſphere; but in ten minutes the thermometer indicated a variation of temperature as great as that between the warmth of ſpring and the ordinary cold of winter. His fingers were benumbed by the cold, and he felt a violent pain in his right ear and jaw, which he aſcribed to the dilatation of the air in theſe organs as well as to the external cold. The beauty of the proſpect which he now enjoyed, however, made amends for theſe inconveniences. At his departure the ſun was ſet on the vallies; but the height to which Mr. Charles was got in the atmoſphere rendered him again viſible, though only for a ſhort time. He ſaw, for a few ſeconds, vapours riſing from the vallies and rivers. The clouds ſeemed to aſcend from the earth, and collect one upon the other, ſtill preſerving their uſual form; only their colour was grey and monotonous for want of ſufficient light in the atmoſphere. By the light of the moon he perceived that the machine was turning round with him in the air; and he obſerved that there were contrary currents which brought him back again. He obſerved alſo, with ſurpriſe, the effects of the wind, and that the ſtreamers of his banners pointed upwards; which, he ſays, could not be the effect either of his aſcent or deſcent, as he was moving horizontally at the time. At laſt, recollecting his promiſe of returning to his friends in half an hour, he pulled the valve, and accelerated his deſcent. When within 200 feet of the earth, he threw out two or three pounds of ballaſt, which rendered the balloon again ſtationary: but, in a little time afterwards, he gently alighted in a field about three miles diſtant from the place whence he ſet out; though, by making allowance for all the turnings and windings of the voyage, he ſuppoſes that he had gone through nine miles at leaſt. By the calculations of M. de Maunier, he roſe at this time not leſs than 10,500 feet high; a height ſomewhat greater than that of Mount Ætna. A ſmall balloon, which had been ſent off before the two brothers ſet out on their voyage, took a direction oppoſite to that of the large one, having met with an oppoſite current of air, probably at a much greater height.

The ſubſequent aerial voyages differ ſo little from that juſt now related, that any particular deſcription of them ſeems to be ſuperfluous. It had occurred to Mr. Charles, however, in his laſt flight, that there might be a poſſibility of directing the machine in the atmoſphere; and this was ſoon attempted by M. Jean-Pierre Blanchard, a gentleman who had, for ſeveral years before, amuſed himſelf with endeavours to fly by mechanical means, though he had never ſucceeded in the undertaking. As ſoon as the diſcovery of the aeroſtatic machines was announced, however, he reſolved to add the wings of his former machine to a balloon, and made no doubt that it would then be in his power to direct himſelf through the air at pleaſure. In his firſt attempt he was fruſtrated by the impetuoſity of a young gentleman, who inſiſted, right or wrong, on aſcending along with him. In the ſcuffle which enſued on this occaſion, the wings and other apparatus were entirely deſtroyed; ſo that M. Blanchard was obliged to commit himſelf to direction of the wind; and in another attempt it was found, that all the ſtrength he could ſupply was ſcarce ſufficient to counteract the impreſſion of the wind in any degree. In his voyage, he found his balloon, at a certain period, acted upon by two contrary winds; but, on throwing out four pounds of ballaſt, he aſcended to a place where he met with the ſame current he had at ſetting out from the earth. His account of the ſenſations he felt during this voyage, was ſomewhat different from that of Mr. Charles; having, in one part of it, found the atmoſphere very warm, in another cold; and having ounce found himſelf very hungry, and at another time almoſt overcome by a propenſity to ſleep. The height to which he aroſe, as meaſured by ſeveral obſervations with mathematical inſtruments, was thought to be very little leſs than 10,000 feet; and he remained in the atmoſphere an hour and a quarter.

The attempts of M. Blanchard to direct his machine through the atmoſphere were repeated in the month of April 1784. Meſſrs. Morveau and Bertrand at Dijon, who raiſed themſelves with an inflammable air-balloon to the height, as it was thought, of 13,000 feet; paſſing through a ſpace of 18 miles in an hour and 25 minutes. M. Morveau had prepared a kind of oars for directing the machine through the air; but they were damaged by a guſt of wind, ſo that only two of them remained ſerviceable; by working theſe, however, they were able to produce a ſenſible effect on the motion of the machine. In a third aerial voyage performed by M. Blanchard, he ſeemed to produce ſome effect by the agitation of his wings, both in aſcending, deſcending, moving ſidewiſe, and even in ſome meaſure againſt the wind; however, this is ſuppoſed, with ſome probability, to have been a miſtake, as, in all his ſucceeding voyages, the effects of his machinery could not be perceived.

The ſucceſs of Meſſrs. Charles and Robert in their former experiments, encouraged them ſoon to repeat them, with the addition of ſome machinery to direct their courſe. Having enlarged their former balloon to the ſize of an oblong ſpheroid 46½ feet long and 27½ in diameter, they made it to float with its longeſt parallel to the horizon. The wings were made in the ſhape of an umbrella without the handle, to the top of which a ſtick was faſtened parallel to the aperture of the umbrella. Five of theſe were diſpoſed round the boat, which was near 17 feet in length. The balloon was filled in three hours, and, with the addition of 450 pounds of ballaſt, remained *in æquilibrio* with the atmoſphere. About noon, on the 19th of September 1784, they began to aſcend very gently in conſequence of throwing out 24 pounds of ballaſt, but were ſoon obliged to throw out eight pounds more in order to avoid running againſt ſome trees. Thus they roſe to the height of 1400 feet, when they perceived ſome thunder-clouds near the horizon. On this they aſcended and deſcended, to avoid the danger, as the wind blew directly towards the threatening clouds; but, from the height of 600 feet to that of 4200 above the ſurface of the earth, the current was quite uniform and in one direction. During their voyage they loſt one of their oars; but found, that by means of thoſe which remained, they conſiderably accelerated their courſe. From the account of their voyage, it appeared that they had paſſed ſafely through the thunder-clouds; as we are informed, that, about 40 minutes after three, they heard a loud clap of thunder; and, three minutes after, another much louder; at which time the thermometer ſunk from 77 to 59 degrees. This ſudden cold occaſioned by the approach of the clouds, condenſed the inflammable air ſo that the balloon deſcended very low, and they were obliged to throw out 40 pounds of ballaſt; yet on examining the heat of the air within the balloon, they found it to be 104°, when that of the external atmoſphere was only 63. When they had got ſo high that the mercury in the barometer ſtood only at 23,94 inches, they found themſelves becalmed; ſo that the machine did not go even at the rate of two feet in a ſecond, though it had before gone at the rate of 24 feet in a ſecond. On this they determined to try the effect of their oars to the utmoſt; and, by working them for 35 minutes, and marking the ſhadow of the balloon on the ground, they ſound, in that time, that they had deſcribed the ſegment of an ellipſis whoſe longeſt diameter was 6000 feet. After having travelled about 150 miles, they deſcended, only on account of the approach of night, having ſtill 200 pounds of ballaſt left.

Having thus related all that has been done with regard to the conducting of aeroſtatic machines through the atmoſphere, we ſhall now relate the attempts that has been made to leſſen their expence, by falling upon ſome contrivance to aſcend without throwing out ballaſt, and to deſcend without loſing any of the inflammable air.

The firſt attempt of this kind was made by the Duke de Chartres; who, on the 15th of July 1784, aſcended with the two brothers, Charles and Robert, from the Park of St. Cloud. The balloon was of an oblong form, made to aſcend with its longeſt diameter horizontally, and meaſured 55 feet in length and 24 in breadth. It contained within it a ſmaller balloon filled with common air; by blowing into which with a pair of bellows, and thus throwing in a conſiderable quantity of common air, it was ſuppoſed that the machine would become ſufficiently heavy to deſcend, eſpecially as, by the inflation of the internal bag, the inflammable air in the external one would be condenſed into a ſmaller ſpace, and thus become ſpecifically heavier. The voyage, however, was attended with ſuch circumſtances as rendered it impoſſible to know what would have been the event of the ſcheme. The power of aſcent with which they ſet out ſeems to have been very great: as, in three minutes after parting with the ground, they were loſt in the clouds, and involved in ſuch a denſe vapour that they could ſee neither the ſky or the earth. In this ſituation they ſeemed to be attacked by a whirlwind, which, beſides turning the balloon three times round from right to left, ſhocked and beat it ſo about, that they were rendered incapable of uſing any of the means propoſed for directing their courſe, and the ſilk ſtuff of which the helm had been compoſed was even torn away. No ſcene can be conceived more terrible than that in which they were now involved. An immenſe ocean of ſhapeleſs clouds rolled one upon another below them, and ſeemed to prevent any return to the earth, which ſtill continued inviſible, while the agitation of the balloon became greater every moment. In this extremity they cut the cords which held the interior balloon, and of conſequence it fell down upon the aperture of the tube that came from the large balloon into the boat, and ſtopped it up. They were then driven upwards by a guſt of wind from below, which carried them to the top of that ſtormy vapour in which they had been involved. They now ſaw the ſun without a cloud; but the heat of hisrays, with the diminiſhed denſity of the atmoſphere had ſuch an effect on the inflammable air, that the balloon ſeemed every moment ready to burſt. To prevent this they introduced a ſtick through the tube, in order to puſh away the inner balloon from its aperture; but the expanſion of the inflammable air puſhed it ſo cloſe, that all the attempts of this kind proved ineffectual. It was now, however, become abſolutely neceſſary to give vent to a very conſiderable quantity of the inflammable air; for which purpoſe the Duke de Chartres himſelf bored two holes in the balloon, which tore open for the length of ſeven or eight feet. On this they deſcended with great rapidity; and would have fallen into a lake, had they not haſtily thrown out 60 pounds of ballaſt, which enabled them juſt to reach the water's edge.

The ſucceſs of the ſcheme for raiſing or lowering aeroſtatic machines by means of bags filled with common air being thus rendered dubious, another method was thought of. This was to put a ſmall aeroſtatic machine with rarefied air under an inflammable air-balloon, but at ſuch a diſtance that the inflammable air of the latter might be perfectly out of the reach of the fire uſed for inflating the former; and thus, by increaſing or diminiſhing the fire in the ſmall machine, the abſolute weight of the whole would be conſiderably diminiſhed or augmented. This ſcheme was unhappily put in execution by thecelebrated M. Pilatre de Rozier, and another gentleman named M. Romaine. Their inflammable-air balloon was about 37 feet in diameter, and the power of the rarefied-air one was equivalent to about 60 pounds. They aſcended without any appearance of danger or ſiniſter accident; but had not been long in the atmoſphere when the inflammable-air balloon was ſeen to ſwell very conſiderably, at the ſame time that the aeronauts were obſerved, by means of teleſcopes, very anxious to get down, and buſied in pulling the valve and opening the appendages to the balloon, in order to facilitate the eſcape of as much inflammable air as poſſible. A ſhort time after this the whole machine was on fire, when they had then attained the height of about three quarters of a mile from the ground. No exploſion was heard; and the ſilk which compoſed the air balloon continued expanded, and ſeemed to reſiſt the atmoſphere for about a minute; after which it collapſed, and the remains of the apparatus deſcended along with the two unfortunate travellers ſo rapidly, that both of them were killed. M. Pilatre ſeemed to have been dead before he came to the ground; but M. Romaine was alive when ſome perſons came up to the place where he lay, though he expired immediately after. Theſe are the moſt remarkable attempts that have been made to improve the ſcience of aeroſtation; though a great number of other expeditions through the atmoſphere have taken place.

But of all the voyages which had been hitherto projected or put in execution, the moſt daring was that of M. Blanchard and Dr. Jeffries acroſs the ſtraits of Dover, which ſeparate Britain from France. This took place on the 7th of January 1785, being a clear froſty morning, with a wind, barely perceptible, at N. N. W. The operation of filling the balloon began at 10 o'clock, and, at three quarters after twelve, every thing was ready for their departure. At one o'clock M. Blanchard deſired the boat to be puſhed off, which now ſtood only two feet diſtant from that precipice ſo finely deſcribed by Shakeſpeare in his tragedy of King Lear. As the balloon was ſcarcely ſufficient to carry two, they were obliged to throw out all their ballaſt except three bags of 10 pounds each; when they at laſt roſe gently, though making very little way on account of there being ſo little wind. At a quarter after one o'clock, the barometer, which on the cliff ſtood at 29.7 inches, was now fallen to 27.3, and the weather proved fine and warm. They had now a moſt beautiful proſpect of the ſouth coaſt of England, and were able to count 37 villages upon it. After paſſing over ſeveral veſſels, they found that the balloon, at 50 minutes after one, was deſcending, on which they threw out a ſack and an half of ballaſt; but as they ſaw that it ſtill deſcended, and that with much greater velocity than before, they now threw out all the ballaſt. This ſtill proving ineffectual, they next threw out a parcel of books they carried along with them, which made the balloon aſcend when they were about midway betwixt France and England. At a quarter paſt two, finding themſelves again deſcending, they threw away the remainder of their books, and, ten minutes after, they had a moſt enchanting proſpect of the French coaſt. Still, however, the machine deſcended; and as they had now no more ballaſt, they were obliged to throw away their proviſions for eating, the wings of their boat, and every other moveable they could poſſibly ſpare. "We threw away, ſays Dr. Jeffries, our only bottle, which, in its deſcent, caſt out a ſteam like ſmoke, with a ruſhing noiſe; and when it ſtruck the water, we heard and felt the ſhock very perceptibly on our car and balloon." All this proving inſufficient to ſtop the deſcent of the balloon, they next threw out their anchors and cords, and at laſt ſtripped off their cloths, faſtening themſelves to certain ſlings, and intending to cut away the boat as their laſt reſource. They had now the ſatisfaction, however, to find that they were riſing; and as they paſſed over high lands between Cape Blanc and Calais, the machine roſe very faſt, and carried them to a greater height than they had been at any former part of their voyage. In a ſhort time after they deſcended ſafely among ſome trees in the foreſt of Guiennes.

It would be tedious as well as unneceſſary to recount all the other aerial voyages that have been performed in our own or other countries: it appeared ſufficient for the purpoſe of this article to notice thoſe which were moſt remarkable and intereſting; and therefore an account of the ingenious Mr. Baldwin's excurſion from Cheſter, with the particular circumſtances attending it, ſhall now cloſe our enumeration.

On the 8th of September 1785, at forty minutes paſt one P. M. Mr. Baldwin aſcended from Cheſter in Mr. Lunardi's balloon. After traverſing in a variety of different directions, he firſt alighted, at 28 minutes after three, about twelve miles from Cheſter, in the neighbourhood of Frodſham; then re-aſcending and purſuing his excurſion, he finally landed at Rixton moſs, five miles N. N. E. of Wavington, and 25 miles from Cheſter. Mr. Baldwin has publiſhed his Obſervations and Remarks made during his voyage, and taken from minutes. Our limits will not admit of relating many of his obſervations; but the few following are ſome of the moſt important and curious. "The ſenſation of aſcending is compared to that of a ſtrong preſſure from the bottom of the car upwards againſt the ſoles of his feet. At the diſtance of what appeared to him ſeven miles from the earth, though by the barometer ſcarcely a mile and a half, he had a grand and moſt enchanting view of the city of Cheſter and its adjacent places below. The river Dee appeared of a red colour; the city very diminutive; and the town entirely blue. The whole appeared a perfect plain, the higheſt building having no apparent height, but reduced all to the ſame level, and the whole terreſtrial proſpect appeared like a coloured map. Juſt after his firſt aſcent, being in a well-watered and maritime part of the country, he obſerved a remarkable and regular tendency of the balloon towards the ſea; but ſhortly after riſing into another current of air, he eſcaped the danger; this upper current, he ſays, was viſible to him at the time of his aſcent, by a lofty ſound ſtratum of clouds flying in a ſafe direction. The perſpective appearance of things to him was very remarkable. The loweſt bed of vapour that firſt appeared as cloud was pure white, in detached fleeces, increaſing as they roſe: they preſently coaleſced, and formed, as he expreſſes it, a ſea of cotton, tufting here and there by the action of the air in the undiſturbed part of the clouds. The whole became an extended white floor of cloud, the upper ſurface being ſmooth and even. Above this white floor he obſerved, at great and unequal diſtances, a vaſt aſſemblage of thunder-clouds, each parcel conſiſting of whole acres in the denſeſt form: he compares their form and appearance to the ſmoke of pieces of ordnance, which had conſolidated as it were into maſſes of ſnow, and penetrated through the upper ſurface or white floor of common clouds, there remaining viſible and at reſt. Some clouds had motions in ſlow and various directions, forming an appearance truly ſtupendous and majeſtic. He endeavours to convey ſome idea of the ſcene as repreſented in *fig.* 11. *A* repreſents a circular view he had from the car of the balloon, himſelf being over the centre of the view, looking down on the white floor of clouds and ſeeing the city of Cheſter through an opening, which diſcovered the landſcape below, limited by ſurrounding vapour, to leſs than two miles in diameter. The breadth of the outer margin defines his apparent height in the balloon, viz. four miles above the white floor of clouds. Mr. Baldwin alſo gives a curious deſcription of his tracing the ſhadow of the balloon over tops of volumes of clouds. At firſt it was ſmall, in ſize and ſhape like an egg; but ſoon encreaſed to the magnitude of the ſun's diſc, ſtill growing larger, and attended with a moſt captivating appearance of an iris encircling the whole ſhadow at ſome diſtance round it, the colours of which were remarkably brilliant. The regions did not feel colder, but rather warmer, than below. The ſun was hotteſt to him when the balloon was ſtationary. The diſcharge of a cannon when the balloon was at a conſiderable height, was diſtinctly heard by the aeronaut; and a diſcharge from the ſame piece, when at the height of 30 yards, ſo diſturbed him as to oblige him for ſafety to lay hold firmly of the cords of the balloon. At a conſiderable height he poured down a pint-bottle full of water; and as the air did not oppoſe a reſiſtance ſufficient to break the ſteam into ſmall drops, it moſtly fell down in large drops. In the courſe of the balloon's track it was found much affected by the water, a circumſtance obſerved in former aerial voyages. At one time the direction of the balloon kept continually over the water, going directly towards the ſea, ſo much as to endanger the aeronaut; the mouth of the balloon was opened, and he in two minutes deſcended into an under current blowing from the ſea: he kept deſcending, and landed at Bellair farm in Rinſley, 12 miles from Cheſter. Here he lightened his car by 31 pounds, and inſtantly re-aſcending, was carried into the interior part of the country, performing a number of different manœuvres. At his greateſt altitude he found his reſpiration free and eaſy. Several bladders which he had along with him crackled and expanded very conſiderably. Clouds and land, as before, appeared on the ſame level. By way of experiment, he tried the upper valve two or three times, the neck of the balloon being cloſe; and remarked, that the eſcape of the gas was attended with a growling noiſe like mill-ſtones, but not near ſo loud. Again, round the ſhadow of the balloon, on the clouds, he obſerved the iris. A variety of other circumſtances and appearances he met with is fancifully deſcribed; and at 53 minutes paſt three he finally landed.

The frequency of aerial voyages, accompanied with particular details of trifling and unintereſting circumſtances, and apparently made with a view to promote the intereſt of particular perſons, regardleſs of any advancement in knowledge, have now ſunk the ſcience of aeroſtation ſo low in the opinion of moſt people, that before giving any account of the moſt proper method of conſtructing theſe machines, it may ſeem neceſſary to premiſe ſomething concerning the uſes to which they may poſſibly be applied. Theſe, according to Mr. Cavallo, are the following:

" The ſmall balloons, eſpecially thoſe made of paper, and raiſed by means of ſpirit of wine, may ſerve to explore the direction of the winds in the upper regions of the atmoſphere, particularly when there is a calm below: they may ſerve for ſignals in various circumſtances, in which no other means can be uſed; and letters or other ſmall things may be eaſily ſent by them, as for inſtance from ſhips that cannot ſafely land on account of ſtorms, from beſieged places, iſlands, or the like. The larger aeroſtatic machines may anſwer all the abovementioned purpoſes in a better manner; and they may, beſides, be uſed as a help to a perſon who wants to aſcend a mountain, a precipice, or to croſs a river; and perhaps one of thoſe machines tied to a boat by a long rope, may be, in ſome caſes, a better ſort of ſail than any that is uſed at preſent. The largeſt ſort of machines, which can take up one or more men, may evidently be ſubſervient to various œconomical and philoſophical purpoſes. Their conveying people from place to place with great ſwiftneſs, and without trouble, may be of eſſential uſe, even if the art of guiding them in a direction different from that of the wind ſhould never be diſcovered. By means of thoſe machines the ſhape of certain ſeas and lands may be better aſcertained; men may aſcend to the tops of mountains they never viſited before; they may be carried over marſhy and dangerous grounds; they may by that means come out of a beſieged place, or an iſland; and they may, in hot climates, aſcend to a cold region of the atmoſphere, either to refreſh themſelves, or to obſerve the ice, which is never ſeen below; and, in ſhort, they may be thus taken to ſeveral places, to which human art hitherto knew of no conveyance.

" The philoſophical uſes, to which theſe machines may be ſubſervient, are numerous indeed; and it may be ſufficient to ſay, that hardly any thing which paſſes in the atmoſphere is known with preciſion, and that principally for want of a method of aſcending into it. The formation of rain, of thunder-ſtorms, of vapours, hail, ſnow, and meteors in general, require to be attentively examined and aſcertained. The action of the barometer, the refraction and temperature of the air in various regions, the deſcent of bodies, the propagation of ſound, &c. are ſubjects that all require a ſeries of obſervations and experiments, the performance of which could never have been properly expected before the diſcovery of aeroſtatic machines."

To thoſe uſes we may add the gratification of curioſity and pleaſure as very ſtrong inducements to the practice of an art, in which, with any tolerable degree of caution, there appears not to be the ſmalleſt danger. Every one who has tried the experiment teſtifies, that the beauty of the proſpect afforded by an aſcent, or the pleaſure of being conveyed through the atmoſphere, cannot be exceeded. No one has felt the leaſt of that giddineſs conſequent upon looking from the top of a very high building or of a precipice, nor have they any of the ſickneſs ariſing from the motion of a veſſel at ſea. Many have been carried by balloons at the rate of 30, 40, or even 50 miles an hour, without feeling the leaſt inconvenience, or even agitation of the wind; the reaſon of which is, that as the machine moves with nearly the velocity of the wind itſelf, they are always in a calm, and without uneaſineſs. Some have apprehended danger from the electricity of the atmoſphere; and have thought that a ſtroke of lightning, or the ſmalleſt electric ſpark, happening near a balloon, might ſet fire to the inflammable air, and deſtroy both the machine and the adventurers. Mr. Cavallo has ſuggeſted ſeveral conſiderations for diminiſhing apprehenſions of this kind. Balloons have been already raiſed in every ſeaſon of the year, and even when thunder has been heard, without injury. In caſe of danger, the aeronauts may either deſcend to the earth, or aſcend above the region of the clouds and thunder-ſtorms. Beſides, as balloons are formed of materials that are not conductors of electricity, they are not likely to receive ſtrokes, eſpecially as by being encompaſſed with air they ſtand inſulated. Moreover, inflammable air by itſelf, or unmixed with a certain quantity of common air, will not burn; ſo that if an electric ſpark ſhould happen to paſs through the balloon, it would not ſet fire to the inflammable air, unleſs a hole was made in the covering.

The general principles of aeroſtation are ſo little different from thoſe of hydroſtatics, that it may ſeem ſuperfluous to inſiſt much upon them. It is a fact univerſally known, that when a body is immerſed in any fluid, if its weight be leſs than an equal bulk of that fluid, it will riſe to the ſurface; but if heavier, it will ſink; and if equal, it will remain in the place where it is left. For this reaſon ſmoak aſcends into the atmoſphere, and heated air in that which is colder. The aſcent of the latter is ſhown in a very eaſy and ſatisfactory manner by bringing a red-hot iron under one of the ſcales of a balance, by which the latter is inſtantly made to aſcend; for, as ſoon as the red-hot iron is brought under the ſcale, the hot air being lighter than that which is colder, aſcends, and ſtrikes the bottom, which is thus impelled upwards, and the oppoſite ſcale deſcends, as if a weight had been put into it.

Upon this ſimple principle depends the whole theory of areoſtation; for it is the ſame thing whether we render the air lighter by introducing a quantity of heat into it, or incloſing a quantity of gas ſpecifically lighter than the common atmoſphere in a certain ſpace; both will aſcend, and for the ſame reaſon. A cubic foot of air, by the moſt accurate experiments, has been found to weigh about 554 grains, and to be expanded by every degree of heat, marked on Fahrenheit's thermometor, about one part in 500 of the whole. By heating a quantity of air, therefore, to 500 degrees of Fahrenheit, we will juſt double its bulk when the thermometer ſtands at 54 in the open air, and in the ſame proportion we will diminiſh its weight; and if ſuch a quantity of this hot air be incloſed in a bag, that the exceſs of the weight of an equal bulk of common air weighs more than the bag with the air contained in it, both the bag and air will riſe into the atmoſphere, and continue to do ſo until they arrive at a place where the external air is naturally ſo much rarefied that the weight becomes equal; and here the whole will float.

The power of hot air in raiſing weights, or rather that by which it is itſelf impelled upwards, may be ſhown in the following manner: Roll up a ſheet of paper in a conical form, and, by thruſting a pin into it near the apex, prevent it from unrolling. Faſten it then, by its apex, under one of the ſcales of a balance by means of a thread, and, having properly counterpoiſed it by weights, put it into the oppoſite ſcale; apply the flame of a candle underneath, you will inſtantly perceive the cone to ariſe, and it will not be brought into equilibrium with the other, but by a much greater weight than thoſe who have never ſeen the experiment would believe. If we try this experiment with more accuracy, by getting proper receptacles made which contain determinate quantities of air, we ſhall find that the power of the heat depends much more on the capacity of the bag which contains it than could well be ſuppoſed. Thus, let a cubical receptacle be made of a ſmall wooden frame covered with paper capable of containing one foot of air, and let the power of a candle be tried with this as above directed for the paper cone. It will then be found that a certain weight may be raiſed; but a much greater one will be raiſed by having a receptacle of the ſame kind which contains two cubic feet; a ſtill greater by one of three feet; a yet greater by one of four feet, &c. and this even though the very ſame candle be made uſe of; nor is it known to what extent even the power of this ſmall flame might be carried.

From theſe experiments it appears, that in the aeroſtatic machines conſtructed on Montgolfier's plan, it muſt be an advantage to have them as large as poſſible; becauſe a ſmaller quantity of fire will then have a greater effect in raiſing them, and the danger from that element, which in this kind of machines is chiefly to be dreaded, will be in a great meaſure avoided. On this ſubject it may be remarked, that as the cubical contents of a globe, or any other figure of which balloons are made, increaſe much more rapidly than their ſurfaces, there muſt ultimately be a degree of magnitude at which the ſmalleſt imaginable heat would raiſe any weight whatever. Thus, ſuppoſing any aeroſtatic machine capable of containing 500 cubic feet, and the air within it to be only one degree hotter than the external atmoſphere; the tendency of this machine to riſe, even without the application of artificial heat, would be near an ounce. Let its capacity be increaſed 16 times; and the tendency to ariſe will be equivalent to a pound, though this may be done without making the machine 16 times heavier than before. It is certain, however, that all aeroſtatic machines have a tendency to produce or preſerve heat within them, which would by no means be imagined by thoſe who have not made the experiment. When Meſſrs. Charles and Roberts made their longeſt aerial voyage of 150 miles, they had the curioſity to try the temperature of the air within their balloon, in compariſon with that of the external atmoſphere; and at this time they found that, when the external atmoſphere was 63°, the thermometer within the balloon ſtood at 104°. Such a difference of temperature muſt have given a machine of the magnitude which carried them a conſiderable aſcending power, independent of any other cauſe, as it amounted to 41 grains on every cubic foot; and therefore in a machine containing 50,000 ſuch feet would have been almoſt 200 pounds. Hence we may eaſily account for what happened at Dijon, and is recorded by M. Morveau. "A balloon, intended to be filled with inflammable air, being completed, was, by way of trial, filled with common air, and in that ſtate expoſed to the atmoſphere. Now it was obſerved, and indeed a ſimilar obſervation had been made before, that the air within the balloon was much hotter than the circumambient air: the thermometer in the former ſtood at 120°; whereas in the latter, even when the ſun ſhone upon it, the thermometer ſtood at 84°. This ſhowed a conſiderable degree of rarefaction within the balloon; and conſequently it was ſuſpected, that, by means of this rarefaction alone, eſpecially if it were to increaſe a little, the balloon might aſcend. On the 30th of May, about noon, the wind being rather ſtrong, agitated the balloon ſo that two men were employed to take care of it; but, notwithſtanding all their endeavours, it eſcaped from its confinement, and, lifting up about 65 pounds weight of cords, equatorial circle, &c. roſe many feet high, and paſſing over ſome houſes, went to the diſtance of 250 yards, where at length it was properly ſecured.

This difference between the external and internal heat being ſo very conſiderable, muſt have a great influence upon aeroſtatic machines, and will undoubtedly influence thoſe filled with inflammable air as well as the other kind. Nor is it unlikely, that the ſhort time which many aerial voyagers have been able to continue in the atmoſphere, may have been owing to the want of a method of preſerving this internal heat. It may naturally be ſuppoſed, and indeed it has always been found, that balloons, in paſſing through the higher regions of the atmoſphere, acquire a very conſiderable quantity of moiſture, not only from the rain or ſnow they ſometimes meet with, but even from the dew and vapour which condenſes upon them. On this an evaporation will inſtantly take place; and, as it is the property of this operation to produce a very violent cold, the internal heat of the balloon muſt be ſoon exhauſted in ſuch a manner as to make it become ſpecifically heavier than the common atmoſphere, and conſequently deſcend in a much ſhorter time than it would have done by the mere loſs of air. To this, in all probability, we are to aſcribe the deſcent of the balloon which carried Meſſrs. Blanchard and Jeffries; and which ſeemed ſo extraordinary to many people, that they were obliged to have recourſe to an imaginary attraction in the waters of the ocean in order to ſolve the phenomenon. This ſuppoſition is rejected by Mr. Cavallo; who explains the matter, by remarking, that in two former voyages made with the ſame machine, it could not long ſupport two men in the atmoſphere; ſo that we had no occaſion to wonder at its weakneſs on this occaſion. "As for its riſing higher, ſays he, juſt when it got over the land, that may be eaſily accounted for. In the firſt place, the two travellers threw out their clothes juſt about that time; ſecondly, in conſequence of the wind's then increaſing, the balloon travelled at a much greater rate than it had done whilſt over the ſea; which increaſe of velocity leſſened its tendency to deſcend: beſides which, the viciſſitudes of heat and cold may produce a very conſiderable effect; for if we ſuppoſe, that the air over the land was colder than that over the ſea, the balloon coming into the latter from the former, continued to be hotter than the circumambient air for ſome time after; and conſequently it was comparatively much lighter when in the cold air over the land, than when in the hotter air over the ſea; hence it floated eaſier in the former than in the latter caſe."

It ſeems indeed very probable, that there was ſomething uncommon in the caſe of Mr. Blanchard's balloon while paſſing over the ſea; for, as it roſe higher after reaching the land than in any former period of the voyage, and likewiſe carried them to the diſtance over land more than half of that which they had paſſed over water, we can ſcarce avoid ſuppoſing, that it had a tendency to deſcend when over the water more than when over land, independent of any loſs of air. Now, it does not appear that the air over the ſea is at all warmer than that above land; on the contrary, there is every reaſon to believe, that the ſuperior reflective power of the land renders the atmoſphere above it warmer than the ſea can do; but it is very natural to ſuppoſe, that the air above the ſea is more moiſt than that above land; and conſequently, by letting fall its moiſture upon the balloon, muſt have occaſioned an evaporation that would deprive the machine of its internal heat, which it would partly recover after it entered the warmer and drier atmoſphere over land.

I ſhall now proceed to the conſtruction of aeroſtatic machines; of which the ſmaller are only for amuſement, or ſome ſlight experiments, and are very eaſily made. As in all of them, however, it is of the utmoſt conſequence to have the weight as little as poſſible, the ſhape becomes an object of great conſideration.

For this purpoſe a ſpherical figure has been mathematically demonſtrated to be the beſt; as capable of containing a greater quantity under a ſmaller ſurface than any other. Thus a perfect ſphere contains leſs ſurface in proportion to its ſolidity than a ſpheroid; a ſpheroid leſs than a cylinder; the latter leſs than a cube; and a cube ſtill leſs than a parallelopiped.

In all caſes, therefore, where we can fill the whole capacity of the balloon with air equally light, the ſpherical figure is undoubtedly to be preferred; and this holds good with regard to all inflammable air-balloons, whether their ſize be great or ſmall; but in the rarefied air ones, where the under part muſt neceſſarily be much colder than the upper, the globular ſhape ſeems not ſo proper. An inverted cone, or truncated pyramid, with the ſmaller part undermoſt, ſeems then to be moſt proper, as it allows the heated air, which has a great tendency to expand as well as to aſcend, to collect in the wide part at the top, while the uſeleſs ſurface in the lower part, and which, in any other figure, would contain only the colder and heavier air, is thus thrown aſide. In fact it has been found, that aeroſtatic machines, raiſed by means of rarefied air, when made of the ſhape of a parallelopiped, or even one deviating ſtill more from the ſhape of a globe, have anſwered the purpoſe as well as they could have been ſuppoſed to do, had ever ſo much care been taken in forming them exactly to that ſhape.

The very firſt machine made by M. Montgolfier was in form of a parallelopiped; and though it contained only 40 cubic feet, ſhowed a very conſiderable power of aſcent. A very large one, 74 feet high, which M. Montgolfier had deſigned to exhibit before the royal family, had the middle part of it priſmatic for about the height of 25 feet; its top was a pyramid of 29 feet; and its lower part was a tuncated cone of near 20 feet. It weighed 1000 pounds; and, notwithſtanding its ſhape, in a very ſhort time manifeſted a power of aſcent equal to 500 pounds.

Another aeroſtatic machine of a ſmall ſize, but of the figure of a parallelopiped, being ſuffered to aſcend with thirty ſheets of oiled paper fixed in a wire frame, and ſet on fire, roſe to a great height, and in 22 minutes could not be ſeen. It ſeems therefore, that, with regard to the ſhape of theſe machines, it is by no means neceſſary to adhere rigidly to that of a ſphere; but that any oblong form anſwers very well.

For experimental purpoſes, both the inflammable and rarefied air-balloons may be made of paper: the former being made of that kind called thin-poſt, varniſhed over with linſeed-oil; the latter either of that or any other kind, without varniſh. In order to avoid the danger of burning, however, it has been propoſed to impregnate the paper of which theſe ſmall rarefied air-balloons are made with ſolution of ſal-ammoniac, alum or ſome other ſalt; but this does not ſeem to be neceſſary. Thoſe filled with inflammable air have been made of gold-beater ſkin or peeled bladders; but the cheaper material of paper is undoubtedly preferable.

For aeroſtatic machines of a larger ſize, the material univerſally employed is varniſhed ſilk; and for thoſe of the rarefied air kind, linen painted over with ſome ſize colour, or lined with paper. The beſt varniſh for an inflammable air-balloon is that made with bird-lime, and recommended by M. Faujas de Saint-Fond, in a treatiſe publiſhed on the ſubject. The following is his method of preparing it: "Take one pound of bird-lime, put it into a new proper earthen pot that can reſiſt the fire, and let it boil gently for about one hour, viz. till it ceaſes to crackle; or, which is the ſame thing, till it is ſo far boiled, as that a drop of it being let fall upon the fire will burn: then pour upon it a pound of ſpirits of turpentine, ſtirring it at the ſame time with a wooden ſpatula, and keeping the pot at a good diſtance from the flame, leſt the vapour of this eſſential oil ſhould take fire. After this, let it boil about ſix minutes longer, then pour upon the whole three pounds of boiling oil of nuts, linſeed or poppy, rendered drying by means of lithrage; ſtir it well, let it boil for a quarter of an hour longer, and the varniſh is made. After it has reſted for 24 hours, and the ſediment has gone to the bottom, decant it into another pot; and when you want to uſe it, warm, and apply it with a flat bruſh upon the ſilk ſtuff, whilſt that is kept well ſtretched. One coat of it may be ſufficient; but if two are neceſſary, it will be proper to give one on each ſide of the ſilk, and to let them dry in the open air while the ſilk remains extended."

Mr. Cavallo gives the following method of preparing this varniſh, which he prefers to that of M. de Saint-Fond. "In order to render linſeed-oil drying, boil it with two ounces of ſaccharum ſaturni and three ounces of lithrage, for every pint of oil, till the oil has diſſolved them, which will be accompliſhed in half an hour; then put a pound of bird-lime and half a pint of the drying oil into a pot, iron or copper pots are the ſafeſt for this purpoſe; the capacity of which may be equal to about one gallon, and let it boil very gently over a charcoal fire till the birdlime ceaſes to crackle, which will be about half or three quarters of an hour; then pour upon it two pints and a half more of drying oil, and let it boil for one hour longer, ſtirring it very frequently with an iron or wooden ſpatula. As the varniſh, whilſt boiling, and eſpecially when it is nearly done, ſwells very much, care ſhould be had to remove, in thoſe caſes, the pot from the fire, and to replace it when the varniſh ſubſides, otherwiſe it will boil over. Whilſt the ſtuff is boiling, the operator ſhould, from time to time, examine whether the varniſh has boiled enough; which is thus known. Take ſome of it upon the blade of a knife, and then, after rubbing the blade of another knife upon it, ſeparate the knives; and when, on this ſeparation, the varniſh begins to form threads between the two, you may conclude that it is done; and, without loſing time, it muſt be removed from the fire. When it is almoſt, though not quite, cold, add about an equal quantity of ſpirit of terpentine; mix it well together, and let it reſt till the next day; when, having warmed it a little, ſtrain and bottle it. If it is too thick, add ſome more ſpirit of terpentine. When this varniſh is laid upon the ſilk, the ſtuff ſhould be made perfectly dry, and ſtretched; ſo that the varniſh, which ought to be uſed lukewarm, may fill up the pores of the ſtuff. The varniſh ſhould be laid once very thin upon one ſide of the ſtuff; and, about 12 hours after, two other coats ſhould be laid on, one on each ſide; and, 24 hours after, the ſilk may be uſed, though, in cold weather, it may be left to dry ſome time longer."

Much has been ſaid in France of their elaſtic gum-varniſh, and its compoſition kept a ſecret; but Mr. Baldwin, after many expenſive trials, declares to the world what he conſiders as the ſecret; and it is merely this: "Take any quantity of caoutchouc, as two ounces averdupois; cut it into ſmall bits with a pair of ſciſſars; put a ſtrong iron ladle, like that uſed by plumbers, over a common pitcoal or other fire. The fire muſt be gentle, glowing, and without ſmoke. When the ladle is hot, much below a red heat, put a ſingle bit into the ladle. If *black* ſmoke iſſues, it will preſently flame and diſappear, or it will evaporate without flame: the ladle is then too hot. When the ladle is leſs hot, put in a ſecond bit, which will produce a *white* ſmoke. This *white* ſmoke will continue during the operation, and evaporate the caoutchouc: therefore no time is to be loſt; but little bits are to be put in, a few at a time, till the whole are melted. It ſhould be continually and gently ſtirred with an iron or braſs ſpoon. Two pounds or one quart of the beſt drying oil, or of raw linſeed-oil, which, together with a few drops of neats-foot oil, has ſtood a month, or not ſo long, on a lump of quick-lime, to make it more or leſs drying, is to be put into the melted caoutchouc, and ſtirred till hot, and the whole poured into a glazed veſſel, through a coarſe gauze or fine ſieve. When ſettled and clear, which will be in a few minutes, it will be fit for uſe either hot or cold." Mr. Baldwin is not at liberty, he obſerves, to publiſh the art of laying on the varniſh: but ſays, that it conſiſts in making no *inteſtine motion* in the varniſh, which would create minute bubbles; that therefore bruſhes are improper. M. Blanchard's method of making elaſtic-gum varniſh for the ſilk of a balloon, is the following: "Diſſolve elaſtic gum, caoutchouc, cut ſmall, in five times its weight of ſpirit of turpentine, by keeping them ſome days together; then boil one ounce of this ſolution in eight ounces of drying linſeed-oil for a few minutes; laſtly, ſtrain it. It muſt be uſed warm." The pieces of ſilk for the balloon muſt be cut out of a proper ſize, according to the dimenſions, after the varniſh is ſufficiently dry. They may be joined by laying about half an inch of the edge of one piece over the edge of the other, and ſewing them by a double ſtitching. M. Blanchard uſes expeditiouſly the following method. He lays about half an inch of the edge of one piece flat over the edge of the other, and paſſes a hot iron over it; in doing which a piece of paper ought to be laid both under and over the ſilk. The joining may be rendered more ſecure by running it with a ſilk thread, and ſticking a ribband over it. The ribbands laid over ſeams may be ſtuck with common glue, provided the varniſh of the ſilk is properly dried. When the glue is quite dry, the ribbands ſhould be varniſhed over, to prevent their being unglued by the rain.

The beſt method of cutting the pieces of ſilk that are to form a balloon, is to deſcribe a pattern of wood or ſtiff card-paper, and then to cut the ſilk upon it. As the edges of ſuch a pattern are not perfect circles, they cannot be deſcribed by a pair of compaſſes: but the beſt method of drawing them is as follows: Firſt, draw, on a flat ſurface two right lines AE *fig.* 1. and BC, perpendicular to each other. Secondly, find the circumference anſwering to the given diameter of the balloon in feet and decimals of a foot; and make AD and DE each equal to a quarter of the circumference, ſo that the whole length AE of the pattern may be equal to half the circumference. Thirdly, divide AD into 18 equal parts; and to the points of diviſion apply the lines *fg*, *hi*, *kl*, &c. parallel to each other, and perpendicular to AD. Fourthly, divide the whole circumference in twice the given number of pieces, and make DC and BB each equal to the quotient of this diviſion; ſo that the whole, BC, is equal to the greateſt breadth of one of theſe pieces. Fifthly, multiply the above-mentioned quotient by the decimals annexed to *fg*, viz. 099619, and then the product expreſſes the length of *fg*; again multiply the ſame length of DE by the decimals annexed to *hi*, and the product expreſſes the length of *hi*; and, in ſhort, the product ariſing from the multiplication of the length of DC by the decimals annexed to each of the parallel lines, gives the length of that line. Laſtly, having found the lengths of all theſe lines, draw by hand a curve-line paſſing through all the extremities of the ſaid lines, and that is the edge of one quarter of the pattern. The other quarters may be eaſily deſcribed, by applying to them a piece of paper cut according to that already found. Suppoſe, for example, that the diameter of the balloon to be conſtructed is 20 feet, and that it is required to make it of 12 pieces: then, in order to draw the pattern for thoſe pieces, find the circumference of the balloon, which is 62.83 feet, and, dividing it by four, the quotient is 15.7 feet; make therefore AD equal to 15.7 feet, and DE likewiſe of the ſame length. Divide the circumference 62.83 by 24, which is double the number of pieces that are to form the balloon, and the quotient, 2.618 feet, is the length of DC and likewiſe of BD; ſo that BC is equal to 5.236 feet. Then, having divided the line AD into 18 equal parts, and having drawn the parallel lines from thoſe points of diviſion, find the length of each of thoſe lines by multiplying 2.618 by the decimals annexed to that line. Thus, 2.618, multiplied by 0.99619, gives 2.608 feet for the length of *fg*; and again, multiplying 2.618 by 0.98481, gives 2.578 feet for the length of *hi*; and ſo of the reſt. In cutting the pieces after ſuch a pattern, care ſhould be taken to leave them about three quarters of an inch all round larger than the pattern, which will be taken up by the ſeams.

To the upper part of the balloon there ſhould be adapted, and well fitted in, a valve opening inwards; to which ſhould be faſtened a ſtring paſſing through a hole made in a ſmall piece of round wood fixed in the loweſt part of the balloon oppoſite to the valve, the end of this ſtring faſtened in the car below, ſo that the aeronaut may open the valve when occaſion requires. The action of this valve may be underſtood from *fig.* 2. A round braſs plate AB has a round hole CD, about two or three inches diameter, covered on both ſides with ſtrong ſmooth leather. On the inſide there is a ſhutter E, alſo of braſs, covered with leather, which is to cloſe the hole CD; being about two inches larger in diameter than the hole. It is faſtened to the leather of the plate AB; and by a ſpring, which need not be very ſtrong, it is kept againſt the hole. The elaſticity of the gas itſelf will help to keep it ſhut. To this ſhutter the ſtring is faſtened, by which it is occaſionally opened for the eſcape of gas. A ſmall ſtring or other ſecurity ſhould be fixed to the ſhutter and the plate, ſo as not to admit the ſhutter to be opened beyond a certain ſafe diſtance. To the lower part of the balloon two pipes ſhould be fixed, made of the ſame ſtuff as the envelope; 6 inches diameter for a balloon of 30 feet, and proportionably larger for balloons of a greater capacity. They muſt be long enough for the car. For balloons of 18 feet and leſs diameter, one neck or pipe will be ſufficient. Theſe pipes are the apertures through which the inflammable gas is introduced into the balloon.

The car or boat is beſt made of wicker-work, covered with leather, and well painted or varniſhed over; and the proper method of ſuſpending it, is by ropes proceeding from the net which goes over the balloon. This net ſhould be formed to the ſhape of the balloon, and fall down to the middle of it, with various cords proceeding from it to the circumference of a circle about two feet below the balloon; and from that circle other ropes ſhould go to the edge of the boat. This circle may be made of wood, or of ſeveral pieces of ſlender cane bound together. The meſhes of the net may be ſmall at top, againſt which part of the balloon the inflammable air exerts the greateſt force; and increaſe in ſize as they recede from the top. A hoop has ſometimes been applied round the middle of the balloon to faſten the net. This, though not abſolutely neceſſary, is beſt made of pieces of cane bound together, and covered with leather.

With regard to the rarefied-air machines, Mr. Cavallo recommends firſt to ſoak the cloth in a ſolution of ſal-ammoniac

Representation of Various Baloons, with the methods of constructing and filling them, & the Implements neceſsary for accelarating or retarding their Motion. See System of Aerostation.

and common ſize, uſing one pound of each to every gallon of water; and when the cloth is quite dry, to paint it over in the inſide with ſome earthy colour, and ſtrong ſize or glue. When this paint has dried perfectly, it will then be proper to varniſh it with oily varniſh, which might dry before it could penetrate quite through the cloth. Simple drying linſeed oil will anſwer the purpoſe as well as any, provided it be not very fluid.

It now only remains to give ſome account of the method by which aeroſtatic machines may be filled with their proper gas, in order to give them their power of aſcending into the atmoſphere; and here we are enabled to determine with much greater preciſion concerning the inflammable-air balloons than the others. With regard to them, a primary conſideration is, the moſt proper method of procuring the inflammable air. But the moſt advantageous methods are, by applying acids to certain metals; by expoſing animal, vegetable, and ſome mineral ſubſtances, in a cloſe veſſel to a ſtrong fire; or by tranſmitting the vapour of certain fluids through red-hot tubes.

1. In the firſt of theſe methods, iron, zinc, and vitriolic acid, are the materials moſt generally uſed. The vitriolic acid muſt be diluted by five or ſix parts of water. Iron may be expected to yield in the common way 1700 times it own bulk of gas; or one cubic foot of inflammable air to be produced by $4\frac{1}{2}$ ounces of iron, the like weight of oil of vitriol, and $22\frac{1}{2}$ ounces of water. Six ounces of zinc, an equal weight of oil of vitriol, and 30 ounces of water, are neceſſary for producing the ſame quantity of gas. It is more proper to uſe the turnings or chippings of great pieces of iron, as of cannon, &c. than the filings of that metal, becauſe the heat attending the effervеſcence will be diminiſhed; and the diluted acid will paſs more readily through the interſtices of the turnings when they are heaped together, than through the filings, which ſtick cloſer to one another. The weight of the inflammable air thus obtained by means of acid of vitriol, is, in the common way of procuring it, generally one ſeventh part of the weight of common air; but with the neceſſary precautions for philoſophical experiments, leſs than one-tenth of the weight of common air. Two other ſorts of elaſtic fluids are ſometimes generated with the inflammable air. Theſe may be ſeparated from it by paſſing the inflammable air through water in which quicklime has been diſſolved. The water will abſorb theſe fluids, cool the inflammable air, and prevent its over heating the balloon when introduced into it.

Fig. 3. repreſents an apparatus deſcribed by Mr. Cavallo as proper for filling balloons of the ſize of two or three feet in diameter with inflammable air, after paſſing it through water. A is the bottle with the ingredients; BCD a tube faſtened in the neck at B, and paſſing through C, the cork of the other bottle, in which there is another hole made to receive the tube on which the balloon is tied. Thus it is plain, that the inflammable air coming out of the tube D will paſs firſt through the water of the bottle E and then into the balloon. Two ſmall caſks may be uſed inſtead of the bottles A and E.

2. Inflammable air may be obtained at a much cheaper rate by the action of fire on various ſubſtances; but the gas which theſe yield is not ſo light as that produced by the effervеſcence of acids and metals. The ſubſtances proper to be uſed in this way are, pit-coal, aſphaltum, amber, rock-oil, and other minerals; wood, and eſpecially oak, camphor-oil, ſpirits of wine, ether, and animal ſubſtances, which yield air in different degrees, and of various ſpecific gravities: but pit-coal is the preferable ſubſtance. A pound of this expoſed to a red heat, yields about three cubic feet of inflammable air, which, whether it be paſſed through water or not, weighs about one-fourth of the weight of common air. Dr. Prieſtley found, as we have elſewhere noticed, that animal or vegetable ſubſtances will yield ſix or ſeven times more inflammable air when the fire is ſuddenly increaſed than when it is gently raiſed, though it be afterwards made very ſtrong. Mr. Cavallo obſerves, that the various ſubſtances above enumerated generally yield all their inflammable air in about one hour's time. The general method is, to incloſe the ſubſtances in iron or earthen veſſels, and thus expoſe them to a ſtrong fire ſufficient to make the veſſels red-hot: the inflammable air proceeding from the aperture of the veſſel is received into a tube or refrigeratory, and, paſſing through the tube or worm, is at laſt collected in a balloon or other veſſel. A gun-barrel has often been uſed for eſſays of this kind. The ſubſtance is put into it ſo as to fill ſix or eight inches of its loweſt part, the remainder filled with dry ſand: a tube, adapted to the mouth of the barrel, is brought into a baſin of water under an inverted receiver; and the part of the barrel containing the ſubſtance being put into the fire and made red-hot, the inflammable air is collected in the inverted receiver. As the gun-barrel cannot ſerve for producing a large quantity of inflammable air, Mr. Cavallo recommends, as the moſt advantageous ſhape, the following contrivance: let the veſſel be made of clay, or rather of iron, in the ſhape of a Florence flaſk, ſomewhat larger, and whoſe neck is longer and larger (as ABC, *fig*. 4.) Put the ſubſtance to be uſed into this veſſel, ſo as to fill about four-fifths or leſs of its cavity AB. If the ſubſtance is of ſuch a nature as to ſwell much by the action of the fire, lute a tube of braſs, or firſt a braſs and then a leaden tube, to the neck C of the veſſel; and let the end D of the tube be ſhaped as in the figure, ſo that going into the water of a tube HI, it may terminate under a ſort of inverted veſſel EF, to the upper aperture of which the balloon G is adapted. Things thus prepared, if the part AB of the veſſel is put into the fire, and made red-hot, the inflammable air produced will come out of the tube CD, and paſſing through the water will at laſt enter into the balloon G. Previous to the operation, as a conſiderable quantity of common air remains in the inverted veſſel EF, which it is more proper to expel, the veſſel EF ſhould have a ſtop-cock K, through which the common air may be ſucked out, and the water aſcend as high as the ſtop-cock. The dimenſions of ſuch an apparatus Mr. Cavallo gives thus: Diameter of largeſt part of the veſſel ABC ſeven inches, length of whole veſſel 16 inches; diameter of its aperture one inch, diameter of the cavity of tube CD three-fourths of an inch; lower aperture of the veſſel EF ſix inches, leaſt height of the veſſel EF 24 inches; its aperture F about two inches. The aperture of the veſſel EF ſhould be at leaſt one foot below the ſurface of the water in HI. Care muſt be taken that the fire uſed in this proceſs be at a ſufficient diſtance, otherwiſe it may happen to fire the inflammable air which may eſcape out of the veſſel EF.

3. The laſt method of obtaining inflammable air was lately diſcovered by Mr. Lavoiſier, and alſo by Dr. Prieſtley. Mr. Lavoiſier made the ſteam of boiling water paſs through the barrel of a gun, kept red-hot by burning coals. Dr. Prieſtley uſes, inſtead of the gum-barrel, a tube of red-hot braſs, upon which the ſteam of water has no effect, and which he fills with the pieces of iron which are ſeparated in the boring of cannon. By this method he obtains an inflammable air, the ſpecific gravity of which is to that of common air as 1 to 13. In this method, not yet indeed reduced to general practice, a tube, about three quarters of an inch in diameter, and about three feet long, is filled with iron turnings; then the neck of a retort, or a cloſe boiler, is luted to one of its ends, and the worm of a refrigeratory is adapted to its other extremity. The middle part of the tube is then ſurrounded with burning coals, ſo as to keep about one foot in length of it red-hot, and a fire is always made under the retort or boiler ſufficient to make the water boil with vehemence. In this proceſs a conſiderable quantity of inflammable air comes out of the worm of the refrigeratory. It is ſaid that iron yields one half more air by this means than by the action of vitriolic acid.

For filling large balloons, a greater apparatus is neceſſary; and the only materials that can, with any certainty of ſucceſs, be employed for producing the proper gas, are, oil of vitriol, and iron filings or turnings.

It has indeed been recommended to uſe zinc inſtead of iron filings, becauſe white vitriol, the ſalt produced by the union of the vitriolic acid and zinc, is much more valuable than the green ſort produced by the union of the ſame acid with iron. But though this is undoubtedly the caſe, it will as certainly be found, upon trial, that the ſuperior price of the zinc will be more than an equivalent for all the advantage that can be derived from the additional price of the white vitriol. For a balloon of 30 feet diameter, Mr. Cavallo recommends 3900 pounds of iron turnings, as much oil of vitriol, and 19,500 pounds of water. Theſe proportions, however, appear too great with reſpect to the acid and metal, and too little with reſpect to the water. Oil of vitriol will not exert its power upon iron unleſs it be diluted with five or ſix times its quantity of water; in which caſe, a much ſmaller quantity of both acid and metal will ſerve. Mr. Lunardi, who from the number of his voyages had certainly much practical knowledge in aeroſtation, filled his balloon at Edinburgh and Glaſgow with about 2000 pounds of iron, as much vitriolic acid, and 12,000 pounds of water. The iron was placed in his veſſels in layers, with ſtraw between them, in order to increaſe the ſurface. His apparatus was not materially different from that of Mr. Cavallo, repreſented by *fig*. 5. where AA are two tubs, about three feet in diameter and nearly two feet deep, inverted in large tubs BB filled with water. In the bottom of each of the inverted tubs a hole is made, and a tube E of tin adapted, which is about ſeven inches in diameter, and ſeven or eight long. To theſe tubes the ſilken ones of the balloon are to be tied. Round each of the tubs B, five, ſix, or more ſtrong caſks are placed; in the top of each two holes are made, and to one of theſe holes a tin tube is adapted, and ſo ſhaped, that, paſſing over the edge of the tub B, and through the water, it may terminate with its aperture under the inverted tub A. The other hole of theſe caſks ſerves for the introduction of materials, and is ſtopped with a wooden plug. When the balloon is to be filled, put the net over it, and let it be ſuſpended as ſhown by CDF; and having expelled all the common air from it, let the ſilken tubes be faſtened round the tin ones EE; and the materials being put into the caſks, the inflammable air, paſſing into the balloon, will ſoon diſtend, and render it capable of ſupporting itſelf; after which the rope GH may be ſlipped off. As the balloon continues to be filled, the net is adjuſted properly round it; the cords that ſurround it are faſtened to the hoop MN; then the boat IK being placed between the two ſets of caſks, is faſtened to the hoop MN;

and every thing that is required to be ſent up, as ballaſt, inſtruments, &c. is placed in it. At laſt, when the balloon is little more than three quarters full, the ſilken tubes are ſeparated from the tin ones of the inverted tubs, and their extremities being tied up, are placed in the boat. Laſtly, the aeronauts being ſeated in the boat, the lateral ropes are ſlipped off, and the machine is abandoned to the air. This apparatus was at laſt reduced by Mr. Lunardi to its utmoſt ſimplicity, by uſing only two large caſks, and ſuffering the vapour to go into the balloon without paſſing through water. Thus his balloon was filled in leſs than half an hour, when, before, it had required two hours at leaſt. The ſinking of his caſks in the ground was alſo an additional convenience, as it created no confuſion, and rendered the materials much more eaſily conveyed into them.

With regard to the rarefied-air balloons, the method of filling them is as follows: A ſcaffold ABCD, *fig.* 6. the breadth of which is at leaſt two-thirds of the diameter of the machine, is elevated about ſix or eight feet above the ground. From the middle of it deſcends a well E, riſing about two or three feet above it, and reaching to the ground, furniſhed with a door or two, through which the fire in the well is ſupplied with fuel. The well ſhould be conſtructed of brick or of plaſtered wood, and its diameter ſhould be ſomewhat leſs than that of the machine. On each ſide of the ſcaffold are erected two maſts HI, KL, each of which has a pulley at the top, and rendered firm by means of ropes KG, KP, HP, HG. The machine to be filled is to be placed on the ſcaffold, with its neck round the aperture of the well. The rope paſſing over the pullies of the two maſts, ſerves, by pulling its two ends, to lift the balloon about 15 feet or more above the ſcaffold; and the reſt of the machine is repreſented by the dotted lines in the figure MNO. The machine is kept ſteady, and held down, whilſt filling, by ropes paſſing through loops or holes about its equator; and theſe ropes may eaſily be diſengaged from the machine, by ſlipping them through the loops when it is able to ſuſtain itſelf. The proper combuſtibles to be lighted in the well, are thoſe which burn quick and clear, rather than ſuch as produce much ſmoke; becauſe it is hot air, and not ſmoke, that is required to be introduced into the machine. Small wood and ſtraw have been found to be very fit for this purpoſe. Mr. Cavallo obſerves, as the reſult of many experiments with ſmall machines, that ſpirits of wine are upon the whole the beſt combuſtible; but its price may prevent its being uſed for large machines. As the current of hot air aſcends, the machine will ſoon dilate, and lift itſelf above the ſcaffold and gallery which was covered by it. The paſſengers, fuel, inſtruments, &c. are then placed in the gallery. When the machine makes efforts to aſcend, its aperture muſt be brought, by means of the ropes annexed to it, towards the ſide of the well a little above the ſcaffold; the fire-place is then ſuſpended in it, the fire lighted in the grate, and the lateral ropes being ſlipped off, the machine is abandoned to the air. It has been determined by accurate experiments, that only one-third of the common air can be expelled from theſe large machines; and therefore the aſcending power of the rarefied air in them can be eſtimated as only equal to half an ounce averdupoiſe for every cubic foot.

The conduct of balloons, when conſtructed, filled, and actually aſcending in the atmoſphere, is an object of great importance in the practice of aeroſtation. The method generally uſed for elevating or lowering the balloons with rarefied air, has been the increaſe or diminution of the fire; and this is entirely at the command of the aeronaut, as long as he has any fuel in the gallery. The inflammable-air balloons have been generally raiſed or lowered by diminiſhing the weight in the boat, or by letting out ſome of the gas through the valve: but the alternate eſcape of the air in deſcending, and diſcharge of the ballaſt for aſcending, will by degrees render the machine incapable of floating; for in the air it is impoſſible to ſupply the loſs of ballaſt, and very difficult to ſupply that of inflammable air. Theſe balloons will alſo riſe or fall by means of the rarefaction or condenſation of the incloſed air, occaſioned by heat and cold. It has been propoſed to aid a balloon in its alternate motion of aſcent and deſcent, by annexing to it a veſſel of common air, which might be condenſed for lowering the machine, and rarefied again, by expelling part of it, for raiſing the machine: but a veſſel adapted to this purpoſe muſt be very ſtrong; and, after all, the aſſiſtance afforded by it would not be very conſiderable. M. Meunier, in order to attain this end, propoſes to incloſe one balloon filled with common air in another filled with inflammable air: as the balloon aſcends, the inflammable air is dilated, and of courſe compreſſes the internal balloon containing the common air; and by diminiſhing its quantity, leſſens its weight. If it ſhould be neceſſary to ſupply this loſs, he ſays it may be eaſily done by a pair of bellows fixed in the gallery. Others have propoſed to annex a ſmall machine with rarefied air to an inflammable-air balloon by ropes, at ſuch a diſtance that the fire of the former might not affect the inflammable air of the latter: the whole apparatus, thus combined, of balloons formed on the two principles of heated and inflammable air, might be raiſed or lowered by merely increaſing or diminiſhing the fire in the lower balloon.

Wings or oars are the only means of this ſort that have been uſed with ſome ſucceſs; and, as Mr. Cavallo obſerves, they ſeem to be capable of conſiderable improvement. Although great effects are not to be expected from them, when the machine goes at a great rate, the beſt methods of moving thoſe wings are by the human ſtrength applied ſimilarly to the oars of a waterman. They may be made in general of ſilk ſtretched between wires, tubes, or ſticks; and when uſed, muſt be turned edgewiſe when they are removed in the direction in which the machine is intended to be impelled, but flat in the oppoſite direction. *Fig.* 7. is the repreſentation of one of M. Blanchard's wings. *Fig.* 8. is one of thoſe by M. Lunardi, which conſiſts of many ſilk ſhutters or valves, ABCD, DECF, &c. every one of which opens on one ſide only, viz. ADBC, opens upon the line AB, DECF opens upon the line DC, &c. In conſequence of this conſtruction, this ſort of oars do not need being turned edgewiſe. *Fig.* 9. repreſents one of the wings uſed by the brothers Roberts in the aerial voyage of the 19th September 1784; and *fig.* 10. repreſents one of the wings conſtructed by Count Zambeccari, which conſiſts of a piece of ſilk ſtretched between two tin tubes ſet at an angle; but theſe wings are ſo contrived as to turn edgewiſe by themſelves when they go on one direction. Other contrivances have been made to direct aeroſtatic machines, but they have moſtly been invented to effect power upon them as upon a ſhip. It appears, however, that they can have no effect when a machine is only moved by the wind alone, becauſe the circumambient air is at reſt in reſpect to the machine. The caſe is quite different with a veſſel at ſea, becauſe the water on which it floats ſtands ſtill whilſt the veſſel goes on; but it muſt be time and experience that can realize the expectations ſuggeſted by theſe contrivances.

ÆRUGINOUS, an epithet given to ſuch things as reſemble or partake of the nature of the ruſt of copper.

ÆRUGINOUS, in ornithology, the trivial name of a ſpecies of the falco.

ÆRUGO, in natural hiſtory, properly ſignifies the ruſt of copper, whether natural or artificial. The former is found about copper mines, and the latter, called verdegris, made by corroding copper-plates with acids.

ÆRUSCATORES, in antiquity, a kind of ſtrolling beggars, not unlike gypſies, who drew money from the credulous by fortune-telling, &c. It was alſo a denomination given to griping exactors, or collectors of the revenue. The Galli, or prieſts of Cybele, were called *æruſcatores magnæ matris*; and μητραγυρται, on account of their being or collecting alms in the ſtreets; to which end they had little bells whereby to draw peoples attention to them, much like ſome orders of mendicants abroad.

AERY, or **AIRY**, among ſportſmen, the neſts or brooding places of birds.

ÆS properly ſignifies copper or money coined of that metal.

ÆS UXORIUM, in antiquity, a ſum paid by bachelors, as a penalty for living ſingle to old age. This tax for not marrying ſeems to have been firſt impoſed in the year of Rome 350, under the cenſorſhip of M. Furius Camillus and M. Poſthumus. At the cenſus, or review of the people, each perſon was aſked, *Et tu ex anima ſententia uxorem habes liberum quærendorum cauſa?* He who had no wife was hereupon fined after a certain rate, called *æs uxorium.*

ÆS *per et libram* was a formula in the Roman law, whereby purchaſes and ſales are ratified. Originally the phraſe ſeems to have been only uſed in ſpeaking of things ſold by weight, or by the ſcales; but it afterwards was uſed on other occaſions. Hence even in adoptions, as there was a kind of imaginary purchaſe; the formula whereof expreſſed, that the perſon adopted was bought *per æs et libram.*

ÆS *Flavum*, yellow copper, among the Romans, an appellation given to the coarſer kinds of braſs.

ÆS *Caldarium*, a term uſed by the German mineraliſts, for a ſubſtance which ſometimes occurs to thoſe who work upon cobalt, and is uſed for the making the fine blue colour called ſmalt.

ÆS *Uſtum*, a chemical preparation, made of thin leaves of copper, ſulphur, and nitre, placed ſtratum ſuper ſtratum in a crucible and ſet in a charcoal fire till all the ſulphur is conſumed; after which, the copper is taken out of the crucible, and reduced to powder. Some quench the leaves of copper in vinegar, and repeat the calcination. Its principal uſe is in colouring glaſs, to which it gives a beautiful tincture. The ſurgeons uſe it as a deterſive, and ſome have given it internally; but it is certainly a very dangerous medicine, and ſhould be avoided.

ÆSALON, in zoology, the name of a ſpecies of the hawk of the long winged kind, called by Engliſh writers the merlin. It is the ſmalleſt of the hawk kind, and formerly much uſed in the diverſion of hawking.

ÆSCH, in zoology, a name by which ſome have called the grayling, or tumbler, a fiſh of the truttaceous kind.

ÆSCHNA, in natural hiſtory, the name of a ſpecies of water-fly, of an aſh colour, with four wings and a long body, hairy near the tail.

ÆSCHYNOMENE, **BASTARD SENSITIVE-PLANT**: A genus of the decandria order, belonging to the diadelphia claſs of plants. For the characters, ſee Syſtem of Botany.

Of this genus there are reckoned ſix ſpecies, 1. The Aſpera. 2. The Americana, 3. The Arborea. 4. The Seſban. 5. The Pumila. 6. The Grandiflora. Theſe plants are propagated by ſeeds, which ſhould be ſown yearly in the ſpring, on a hot bed; and when the plants have ſtrength enough to be removed, they ſhould each be put into a ſeparate pot filled with light earth, and plunged into a hot-bed.

ÆSCHYNOMENOUS, plants among botaniſts, are thoſe properly called ſenſitive plants.

ÆSCULAPII Anguis, an harmleſs ſort of ſnake found in Spain and Italy.

ÆSCULAPIUS, in Heathen mythology, the god of phyſic, was the ſon of Apollo and the nymph Coronis. Alſo the antient name for the conſtellation Ophiucus.

ÆSCULUS, the Horse-chesnut: A genus of the monogynia order, belonging to the heptandria claſs of plants; and ranking, in the natural method, under the 39th order, Trihilatæ. For the characters, ſee Syſtem of Botany.

There are two ſpecies of this plant. 1. The hippocaſtanum, or common horſe-cheſnut. It was brought from the northern parts of Aſia about the year 1550. This tree makes a noble appearance all the month of May, the extremities of the branches being terminated by fine ſpikes of flowers ſpotted with roſe colours, ſo that the whole tree ſeems covered with them.

2. The pavia, or ſcarlet-flowering horſe-cheſnut, a native of Carolina, the Braſils, and the Eaſt. The firſt ſpecies is propagated from the nuts. In autumn, therefore, when they fall, a ſufficient quantity ſhould be gathered. Theſe ſhould be ſown ſoon afterwards in drills, about two inches aſunder. The ſecond ſpecies is propagated by budding it upon the young plants of the horſe-cheſnut.

ÆSNECY, in law, priority of age among copartners.

ÆSPING, in zoology, a ſpecies of coluber.

ÆSTPHARA, incineration or burning of the fleſh, or any part of the body.

ÆSTIMATIO capitis, a term met with in old law-books for a fine anciently ordained to be paid for offences committed againſt perſons of quality, according to their ſeveral degrees.

ÆSTIVAL, in a general ſenſe, denotes ſomething connected with, or belonging to, ſummer. Hence æſtival ſign, æſtival ſolſtice, &c.

ÆSTRUS, a ſpecies of the beetle.

ÆSTUARIA, in geography, denotes an arm of the ſea, which runs a good way within land. Such is the Briſtol channel, and many of the friths of Scotland.

ÆSTUARIES, in ancient baths, were ſecret paſſages from the hypocauſtum into the chambers.

ÆSTUARY, among phyſicians, a vapour-bath, or any other inſtrument for conveying heat to the body.

ÆSYMNIUM, in antiquity, a monument erected to the memory of the heroes, by Æſymnus the Megarean. He conſulting the oracle in what manner the Megareans might be moſt happily governed, anſwered, "If they held conſultation with the more numerous:" whom he taking for the dead, built the ſaid monument, and a ſenate-houſe that took within its compaſs the monument: imagining, that thus the dead would aſſiſt at their conſultations.

ÆSYMNETIC *Monarchy*, implies an elective government, the ſame as Germany, Poland, &c.

ÆTATE *Probando*, in law, a writ to enquire the ages of the king's tenants; now diſuſed. Vide Stat. Car. 2. Reg. Orig. 294.

ÆTHALE, ſignifies the ſoot of metallurgic furnaces.

ÆTHER, is uſually underſtood of a thin, ſubtile matter, or medium, much finer and rarer than air; which commencing from the limits of our atmoſphere, poſſeſſes the whole heavenly ſpace. The philoſophers cannot conceive that the largeſt part of the creation ſhould be perfectly void; and therefore they fill it with a ſpecies of matter under the denomination of æther. But they vary extremely as to the nature and character of this æther. Some conceive it as a body *ſui generis*, appointed only to fill up the vacuities between the heavenly bodies; and therefore confined to the regions above our atmoſphere. Others ſuppoſe it of ſo ſubtile and penetrating a nature, as to pervade the air, and other bodies, and poſſeſs the pores and other intervals thereof. Others deny the exiſtence of any ſuch ſpecific matter; and think the air itſelf, by that immenſe tenuity and expanſion it is found capable of, may diffuſe itſelf through the interſtellar ſpaces, and be the only matter found therein.

In effect, æther, being no object of our ſenſe, but the mere work of imagination, brought only upon the ſtage for the ſake of hypotheſis, or to ſolve ſome phenomenon, real or imaginary; authors take the liberty to modify it how they pleaſe. Some ſuppoſe it of an elementary nature, like other bodies; and only diſtinguiſhed by its tenuity, and the other affections conſequent thereon: which is the philoſophical æther. Others will have it of another ſpecies, and not elementary; but rather a ſort of fifth element, of a purer, more refined, and ſpirituous nature, than the ſubſtances about our earth; and void of the common affections thereof, as gravity, &c. The heavenly ſpaces being the ſuppoſed region or reſidence of a more exalted claſs of beings, the medium muſt be more exalted in proportion. Such is the ancient and popular idea of æther, or ætherial matter.

The term æther being thus embarraſſed with a variety of ideas, and arbitrarily applied to ſo many different things, the later and ſeverer philoſophers chooſe to ſet it aſide, and in lieu thereof ſubſtitute other more determinate ones. Thus the Carteſians uſe the term *materia ſubtilis*; which is their æther: and Sir Iſaac Newton, ſometime a *ſubtile ſpirit*, as in the cloſe of his *Principia*; and ſometimes a *ſubtile* or *ætherial medium*, as in his *Optics*.

The truth is, there are abundance of conſiderations, which ſeem to evince the exiſtence of ſome matter in the air, much finer than the air itſelf. There is an unknown ſomething, which remains behind when the air is taken away; as appears from certain effects which we ſee produced *in vacuo*. Heat, Sir Iſaac Newton obſerves, is communicated through a vacuum almoſt as readily as through air: but ſuch communication cannot be without ſome interjacent body, to act as a medium. And ſuch body may be ſubtile enough to penetrate the pores of glaſs; and may be very well concluded to permeate thoſe of all other bodies, and conſequently be diffuſed through all the parts of ſpace which anſwers to the full character of an æther. See Heat.

The exiſtence of ſuch an ætherial medium being ſettled, that author proceeds to its properties; inferring it to be not only rarer and more fluid than air, but exceedingly more elaſtic and active: in virtue of which properties, he ſhows, that a great part of the phenomena of nature may be produced by it. To the weight, e. g. of this medium, he attributes gravitation, or the weight of all other bodies; and to its elaſticity, the elaſtic force of the air and of nervous fibres, and the emiſſion, refraction, reflection, and other phenomena of light; as alſo, ſenſation, muſcular motion, &c. In fine, this ſame matter ſeems the *primum mobile*, the firſt ſource or ſpring of phyſical action in the modern ſyſtem.

The Carteſian æther is ſuppoſed not only to pervade, but adequately to fill, all the vacuities of bodies; and thus to make an abſolute plenum in the univerſe.

But Sir Iſaac Newton overturns this opinion, from divers conſiderations; by ſhowing, that the celeſtial ſpaces are void of all ſenſible reſiſtance: for, hence it follows, that the matter contained therein muſt be immenſely rare, in regard the reſiſtance of bodies is chiefly as their denſity; ſo that if the heavens were thus adequately filled with a medium or matter, how ſubtile ſoever, they would reſiſt the motion of the planets and comets much more than quickſilver or gold.

The late diſcoveries in electricity have thrown great light upon this ſubject, and rendered it extremely probable that the æther ſo often talked of is no other than the electric fluid, or ſolar light, which diffuſes itſelf throughout the whole ſyſtem of nature.

Æther, in chemiſtry, the lighteſt, moſt volatile, and moſt inflammable of all liquids, is produced by diſtillation of acids with rectified ſpirit of wine.

ÆTHERIAL, Etherius, ſomething that belongs to, or partakes of, the nature of æther. Thus we ſay, the *ætherial ſpace*, *ætherial regions*, &c.

Some of the ancients divided the univerſe, with reſpect to the matter contained therein, into elementary and ætherial.

Under the ætherial world was included all that ſpace above the uppermoſt element, viz. fire. This they ſuppoſed to be perfectly homogeneous, incorruptible, unchangeable, &c. See Corruption. The Chaldees placed an ætherial world between the empyreum and the region of the fixed ſtars. Beſide which, they ſometimes alſo ſpeak of a ſecond ætherial world, meaning by it the ſtarry orb; and a third ætherial world, by which is meant the planetary region.

ÆTHIOPS, *Mineral*, *Martial*, and *Antimonial*, explained under thoſe heads.

ÆTHUSA, in botany, a genus of the pentandria digynia claſs; and, in the natural method, ranking under the 45th order, *Umbellatæ*. For its characters, ſee Syſtem of Botany. There is but one ſpecies, viz. the æthuſa ſynapium, fools-parſley, or leſſer hemlock, a native of Britain, which grows in corn-fields and gardens. This plant, from its reſemblance to common parſley, hath ſometimes been miſtaken for it; and when eaten, it occaſions ſickneſs. If the curled-leaved parſley only was cultivated in our gardens, no ſuch miſtakes would happen in future. Cows, horſes, ſheep, goats, and ſwine, eat it. It is noxious to geeſe.

AETIANS, in church-hiſtory, a branch of Arians who maintained, that the Son and Holy Ghoſt are in all things diſſimilar to the Father.

ÆTIOLOGY, is that part of pathology which is employed in exploring the cauſes of diſeaſes.

ÆTITES, or Eagle-stone, in natural hiſtory, a flinty or cruſtated ſtone, hollow within, and containing a nucleus, which, on ſhaking, rattles within. It was formerly in repute for ſeveral extraordinary magic as well as medical powers; ſuch as preventing abortion, diſcovering thieves, and other ridiculous properties. The word is formed from αετος, "eagle;" the popular tradition being, that it is found in the eagle's neſt, whither it is ſuppoſed to be carried while the female ſits, to prevent her eggs from being rotten. It is found in ſeveral parts: near Trevoux in France, one can ſcarce dig a few feet, without finding conſiderable ſtrata or beds of the coarſer or ferruginous kind. They are originally ſoft, and of the colour of yellow oaker. But the fineſt and moſt valued of all the eagle-ſtones are accidental ſtates of one or other of our common pebbles.

ÆTNA SALT, Sal Ætnæ, a name given by ſome authors to the ſal ammoniac, which is found on the ſurface and ſides of the openings of Mount Ætna, and other burning mountains, after their eruptions; and ſometimes on the ſurface of the ferruginous matter which they throw out. This ſalt makes a various appearance in many caſes: it is ſometimes found in large and thick cakes, ſometimes only in form of a thin powder, ſcattered over the ſurface of the earth and ſtones. Some of this ſalt is yellow, ſome white, and ſome greeniſh. This ſalt is a concrete of nitre, ſulphur, and vitriol, burnt and ſublimed together: Borelli found once a vaſt quantity of this ſalt on Mount Ætna, and tried many experiments on it; from whence he concluded, that this ſalt is ſo far from occaſioning the exploſions of that mountain, as ſome have ſuppoſed, that it does not exiſt in it, but is formed during the burning. Phil. Tranſ. Nº. 100.

AFFA, a weight uſed on the Gold Coaſt of Guinea. It is equal to an ounce, and the half of it is called eggeba. Moſt of the blacks on the Gold Coaſt give theſe names to thoſe weights.

AFFECTIO Bovina, a diſorder incident to cattle, occaſioned by a little worm bred between the fleſh and the ſkin, whick works its way all over the body.

AFFECTION, in a general ſenſe, implies an attribute inſeperable from its ſubject. Thus magnitude, figure, weight, &c. are affections of all bodies; and love, fear, hatred, &c. are affections of the mind.

Affection (ſignifying a ſettled bent of mind toward a particular being or thing) occupies a middle ſpace between diſpoſition on the one hand, and paſſion on the other. It is diſtinguiſhable from Diſpoſition, which being a branch of one's nature, originally, muſt exiſt before there can be an opportunity to exert it upon any particular object; whereas affection can never be original, becauſe, having a ſpecial relation to a particular object, it cannot exiſt till the object has once at leaſt been preſented. It is alſo diſtinguiſhable from Paſſion, which, depending on the real or ideal preſence of its object, vaniſhes with its object: whereas Affection is a laſting connection; and, like other connections, ſubſiſts even when we do not think of the perſon. A familiar example will illuſtrate this. There may be in one perſon's mind a diſpoſition to gratitude, which, through want of an object, happens never to be exerted; and which therefore is never diſcovered even by the perſon himſelf. Another, who has the ſame diſpoſition, meets with a kindly office that makes him grateful to his benefactor: an intimate connection is formed between them, termed affection; which, like other connexions, has a permanent exiſtence, though not always in view. The affection, for the moſt part, lies dormant, till an opportunity offers for exerting it: in that circumſtance, it is converted into paſſion of gratitude; and the opportunity is eagerly ſeized of teſtifying gratitude in the warmeſt manner.

Affection, among phyſicians, ſignifies the ſame as diſeaſe. Thus the hyſteric affection is the ſame with the hyſteric diſeaſe.

AFFERERS, or Afferors, in law, perſons appointed in court-leets, court-barons, &c. to ſettle, upon oath, the fines to be impoſed upon thoſe who have been guilty of faults arbitrarily puniſhable.

AFFETUOSO, or Con Affetto, in the Italian muſic, intimates that the part to which it is added ought to be played in a tender moving way, and conſequently rather ſlow than faſt.

AFFIANCE, in law, denotes the mutual plighting of troth between a man and woman to marry each other.

AFFIDATIO Dominorum ſignifies an oath taken by the lords in parliament.

AFFIDATUS, in law, denotes a tenant by fealty.

AFFIDAVIT, ſignifies an oath in writing, ſworn before ſome perſon who is authoriſed to take the ſame.

AFFILLIATION, ſynonymous with adoption.

AFFINAGE implies the refining of gold or other metals.

AFFINITY, among civilians, implies a relation contracted by marriage; in contradiſtinction to conſanguinity, or relation by blood.—Affinity does not found any real kinſhip; it is no more than a kind of fiction, introduced on account of the cloſe relation between huſband and wife. It is even ſaid to ceaſe when the cauſe of it ceaſes: hence a woman who is not capable of being a witneſs for her huſband's brother during his life-time, is allowed for a witneſs when a widow, by reaſon the affinity is diſſolved. Yet with regard to the contracting marriage, affinity is not diſſolved by death, though it be in every thing elſe.

There are ſeveral degrees of affinity, wherein marriage was prohibited by the law of Moſes: thus, the ſon could not marry his mother, nor his father's wife, Lev. xviii. 7. et ſeq. The brother could not marry his ſiſter, whether ſhe were ſo by the father only or by the mother only, and much leſs if ſhe was his ſiſter both by the ſame father and mother: the grand-father could not marry his grand-daughter, either by his ſon or daughter. No one could marry the daughter of his father's wife; nor the ſiſter of his father or mother. Nor the uncle his niece; nor the aunt her nephew. Nor the nephew the wife of his uncle by the father's ſide. The father-in-law could not marry his daughter-in-law: nor the brother the wife of his brother, while living; nor even after the death of his brother, if he left children. If he left no children, the ſurviving brother was to raiſe up children to his deceaſed brother, by marrying his widow. It was forbidden to marry the mother and the daughter at one time, or the daughter of the mother's ſon, or the daughter of her daughter, or two ſiſters together. It is true the patriarchs before the law married their ſiſters, as Abraham married Sarah, who was his father's daughter by another mother; and two ſiſters together, as Jacob married Rachel and Leah; and their own ſiſters by both father and mother, as Seth and Cain. But theſe caſes are not to be conſidered as examples: becauſe in ſome they were authoriſed by neceſſity; in others by cuſtom; and the law was not then in being. If ſome other examples may be found, either before or ſince the law, the ſcripture expreſsly diſapproves of them, as Reuben's inceſt with Balah his father's concubine, and the action of Ammon with his ſiſter Tamar; and that of Herod-Antipas, who married Herodias his ſiſter-in-law, his brother Philip's wife, while her huſband was yet living.

Affinity is alſo uſed to denote conformity or agreement: thus we ſay, the affinity of languages, the affinity of words, the affinity of ſounds, &c.

Affinity, or Elective Attraction, are terms uſed by modern chemiſts to expreſs that peculiar propenſity which different ſpecies of matter have to unite and combine with certain other bodies excluſively, or in preference to any other connection.

AFFION, the ſame as opium.

AFFIRMATION, in logic, the aſſerting the truth of any propoſition.

Affirmation, in law, denotes an indulgence allowed to the people called Quakers; who, in caſes where an oath is required from others, may make a ſolemn affirmation that what they ſay is true; and if they make a falſe affirmation, they are ſubject to the penalties of perjury. But this relates only to oaths taken to the government, and on civil occaſions; for Quakers are not permited to give their teſtimony in any criminal caſe, &c.

Affirmation is alſo uſed for the ratifying or confirming the ſentence or decree of ſome inferior court: Thus we ſay, the houſe of lords affirmed the decree of the lord-chancellor, or the decree of the lords of ſeſſion.

AFFIRMATIVE, in grammar. Authors diſtinguiſh affirmative particles; ſuch is, *yes*.—The term *affirmative* is ſometimes alſo uſed ſubſtantively. Thus we ſay, the affirmative is the more probable ſide of the queſtion: there were ſo many votes, or voices, for the affirmative.

AFFIX, in grammar, a particle added at the cloſe of a word, either to diverſify its form, or alter its ſignification. We meet with *affixes* in the Saxon, the German, and other northern languages; but more eſpecially in the Hebrew, and other oriental tongues. The Hebrew *affixes* are ſingle ſyllables, frequently ſingle letters, ſubjoined to nouns and verbs; and contribute not a little to the brevity of that language. The oriental languages are much the ſame as to the radicals, and differ chiefly from each other as to *affixes* and *prefixes*.

AFFLATUS, literally denotes a blaſt of wind, breath, or vapour, ſtriking with force againſt another body. The word is Latin, formed from *add* "to," and *flare*, "to blow." Naturaliſts ſometimes ſpeak of the afflatus of ſerpents. Tully uſes the word figuratively, for a divine inſpiration; in which ſenſe he aſcribes all great and eminent accompliſhments to a divine afflatus.

AFFLICTION, in a general ſenſe, ſignifies any thing that cauſes a ſenſation of pain; a diſagreeable circumſtance; a calamity; miſery, adverſity, diſtreſs. "All affliction is naturally grievous." Hooker.

Affliction is not itſelf, in propriety of medical ſpeech, a diſeaſe, but it produces many: for whatever excites envy, anger or hatred, produces diſeaſes from tenſe fibres; as whatever excites fear, grief, joy, or delight, begets diſeaſes from relaxation.

AFFLUX, in electricity, is oppoſed to efflux; and both terms were uſed by the Abbé Nolet, as alſo by Dr. Watſon, previous to the diſcovery of poſitive and negative electrics.

AFFORAGE, in the French cuſtoms, a duty paid to the lord of a diſtrict, for permiſſion to ſell wine, or other liquors, within his ſeignory. Afforage is alſo uſed for the rate or price of proviſions laid and fixed by the provoſt or ſheriffs of Paris.

AFFORCEMENT, in antient fortification, implies a fortified caſtle, or country-houſe well ſecured for defence.

AFFORESTING, Afforestatio, the turning ground into foreſt. William the Conqueror, and his ſucceſſors, continued afforeſting the lands of the ſubject for many reigns; till the grievance became ſo notorious, that people of all degrees and denominations were brought to ſue for relief; which was at length obtained, and commiſſions were granted to ſurvey and perambulate the foreſt, and ſeperate all the new afforeſted lands, and re-convert them to the uſes of their proprietors, under the name and quality of *purlieu* or *pouralle land*.

AFFRA, or Affrayment, in law, formerly ſignified the crime of affrighting other perſons, by appearing in unuſual armour, brandiſhing a weapon, &c. but, at preſent, it denotes a ſkirmiſh or fight between two or more.

AFFRONTEE, in heraldry, an appellation given to animals facing one another on an eſcutcheon; a kind of bearing which is otherwiſe called *confrontee*, and ſtands oppoſed to *adoſſee*.

AFFUIAGE, in ancient records, ſignifies the right of fuel from a certain foreſt, a ſtipulation uſual and neceſſary in grants to a leſſee.

AFFUSION, the act of pouring ſome fluid ſubſtance on another body. Dr. Grew gives ſeveral experiments of the luctation ariſing from the affuſion of divers menſtruums on all ſorts of bodies. Divines and church hiſtorians ſpeak of baptiſm by affuſion; which amounts to much the ſame with what we now call ſprinkling.

AFLOAT, in ſea language, ſignifies the ſtate of a ſhip when ſhe is buoyed up by the water from the ground.

AFOBA, in botany, the kidney-bean produced in Guinea, which the natives apply to expel cutaneous foulneſſes. Philoſ. Tranſ. N°. 232.

AFRICAN COMPANY, a ſociety of merchants, eſtabliſhed by king Charles II. for trading to Africa; which trade is now laid open to all his majeſty's ſubjects, paying 10 per cent. for maintaining the forts.

AFRICANUS FLOS, a flower of little or no repute in the botanical ſyſtem.

AFRICTA ſignifies the wafers uſed by the ancients in their ſacrifices.

AFSLAGERS, perſons appointed by the burgomaſters of Amſterdam to preſide over the public ſales made in that city. They muſt always have a clerk of the ſecretary's office with them, to take an account of the ſale. They are much the ſame as our brokers or auctioneers.

AFT, in the ſea language, the ſame with ABAFT.

AFTER-BIRTH, in midwifery, ſignifies the membranes which ſurround the infant in the womb, generally called the ſecundines.

AFTERMATH, in huſbandry, ſignifies the graſs which ſprings or grows up after mowing.

AFTERNOON, the latter half of the artificial day, or that ſpace between noon and night.

AFTER-PAINS, in midwifery, exceſſive pains felt in the groin, loins, &c. after the woman is delivered.

AFTER-SWARMS, in the management of bees, are thoſe which leave the hive ſome time after the firſt have ſwarmed.

AFTO, in botany, ſo called by the natives of Guinea in Africa, the ſame as Eryſimum, or hedge-muſtard, uſually adminiſtered by thoſe people for the head-ach. Phil. Tranſ. N°. 232.

AGA, in the Turkiſh language, ſignifies a great lord or commander. Hence the aga of the Janiſſaries is the commander in chief of that corps; as the general of horſe is denominated *ſpahiclar aga*. The aga of the Janiſſaries is an officer of great importance. He is the only perſon who is allowed to appear before the Grand Seignior without his arms acroſs his breaſt in the poſture of a ſlave. Eunuchs at Conſtantinople are in poſſeſſion of moſt of the principal poſts of the ſeraglio. The title *aga* is given to them all, whether in employment or out. This title is alſo given to all ſuch men without employ, and eſpecially to wealthy land-holders.—We find alſo *agas* in other countries. The chief officers under the Khan of Tartary are called by this name. And among the Algerines, we read of *agas* choſen from among the *boluk baſhis* (the firſt rank of military officers), and ſent to govern in chief the towns and garriſons of that ſtate. The *aga* of Algiers is the preſident of the divan, or ſenate. For ſome years the *aga* was the ſupreme officer, and governed the ſtate in the place of baſhaw, whoſe power dwindled to a ſhadow. But the ſoldiery riſing againſt the *boluk baſhis*, or *agas*, maſſacred moſt of them, and transferred the ſovereign power to the calif, with the title of Dey, or King.

AGALACTIA, in phyſic, implies an inſufficiency of milk in the breaſts of a nurſe.

AGALLOCHUM, ſynonymous with the wood of aloes.

AGALMATA, in antiquity, a term originally uſed to ſignify any kind of ornaments in a temple; but afterwards for the ſtatutes only, as being moſt conſpicuous.

AGANIPPIDES, in antient poetry, a deſignation given to the muſes, from a fountain of mount Helicon, called Aganippe.

AGANIPPE, in antiquity, a fountain of Bœotia at mount Helicon, on the borders between Phocis and Bœotia, ſacred to the muſes, and running into the river Permeſſeus. Ovid ſeems to make Aganippe and Hippocrene the ſame. Solinus more truly diſtinguiſhes them, and aſcribes the blending them to poetical licence.

AGAPE, in eccleſiaſtical hiſtory, the love-feaſt, or feaſt of charity, in uſe among the primitive Chriſtians; when a liberal contribution was made by the rich to feed the poor. The word is Greek, and ſignifies *love*. St. Chryſoſtom gives the following account of this feaſt, which he derives from the apoſtolical practice. He ſays, "the firſt Chriſtians had all things in common, as we read in the Acts of the Apoſtles; but when that equality of poſſeſſions ceaſed, as it did even in the apoſtles time, the agape, or love-feaſt, was ſubſtituted in the room of it. Upon certain days, after partaking of the Lord's Supper, they met at a common feaſt; the rich bringing proviſions, and the poor who had nothing being invited." It was always attended with receiving the holy ſacrament; but there is ſome difference between the ancient and modern interpreters as to the circumſtance of time, viz. Whether this feaſt was held before or after the communion. St. Chryſoſtom is of the latter opinion; the learned Dr. Cave of the former. Theſe love-feaſts, during the three firſt centuries, were held in the church without ſcandal or offence; but, in after times, the heathens began to tax them with impurity. This gave occaſion to a reformation of theſe *agapæ*. The kiſs of charity, with which the ceremony uſed to end, was no longer given between different ſexes; and it was expreſsly forbidden to have any beds or couches, for the conveniency of thoſe who ſhould be diſpoſed to eat more at their eaſe. Notwithſtanding theſe precautions, the abuſes committed in them became ſo notorious, that the holding of them, in churches at leaſt, was ſolemnly condemned, at the council of Carthage, in the year 397.

AGAPETÆ, in eccleſiaſtical hiſtory, a name given to certain virgins and widows, who, in the ancient church, aſſociated themſelves with, and attended on, eccleſiaſtics, out of a motive of piety and charity.

In the primitive days there were women inſtituted Deaconeſſes; who, devoting themſelves to the ſervice of the church, took up their abode with the miniſters, and aſſiſted them in their functions. In the fervour of primitive piety, there was nothing ſcandalous in theſe ſocieties: but they afterwards degenerated into libertiniſm; inſomuch, that St. Jerome aſks, with indignation, *unde agapetarum peſtis in eccleſias introiit?* This gave occaſion to councils to ſuppreſs them. St. Athanaſius mentions a prieſt, named Leontius, who, to remove all occaſion of ſuſpicion, offered to mutilate himſelf, to preſerve his beloved companion.

AGARIC, in pharmacy, a kind of furious excreſcence, growing on the trunks and large branches of ſeveral trees; but chiefly upon ſome kinds of oak when old and decayed. It was in much eſteem among the ancients as a purge, but has been judiciouſly exploded by the moderns, from its occaſioning inſupportable nauſeas.

Mineral AGARIC, a marley earth reſembling the vegetable of that name in colour and texture. It is found in the fiſſures of rocks, and on the roofs of caverns; and is ſometimes uſed as an aſtringent in fluxes, hemorrhages, &c.

AGARICUS, or MUSHROOM, a genus of the order of fungi, belonging to the cryptogamia claſs of plants.

Botanical writers enumerate 55 ſpecies belonging to this genus; of which the moſt remarkable is the campeſtris, or common muſhroom: it has the top or cap firſt of a dirty cream colour, convex, and, if but juſt expanding, the under part, or what is called the gills, is of a bright fleſh red: this colour laſts but a little time before it turns darker; and when the plant is old, or has been ſome time expanded, the gills become of a dark brown, the cap almoſt flat, of a dirty colour, and often a little ſcaly.

AGASYLLIS, in materia medica, implies the Greek name of gum ammoniac.

AGATE, or ACHAT, among the Greeks and Latins, Αχατης, and *Achates*, from a river in Sicily, on the banks of which it was firſt found, a very extenſive genus of the ſemipellucid gems. Theſe ſtones are variegated with veins and clouds, but have no zones like thoſe of the onyx. They are compoſed of cryſtal debaſed by a large quantity of earth, and not formed, either by repeated incruſtations round a central nucleus, or made up of plates laid evenly on one another; but are merely the effect of one ſimple concretion, and variegated only by the diſpoſition given, by the fluid they were formed in, to their differently coloured veins or matters.

AGATE, among antiquaries, denotes a ſtone of this kind engraven by art. In this ſenſe, agates make a ſpecies of antique gems; in the workmanſhip whereof we find eminent proofs of the great ſkill and dexterity of the ſculptors. Several agates of exquiſite beauty are preſerved in the cabinets of the curious; but the facts or hiſtories repreſented on theſe antique agates, however well executed, are now become ſo obſcure, and their explications ſo difficult, that ſeveral diverting miſtakes and diſputes have ariſen among thoſe who undertook to give their true meaning.

AGATE is alſo a name of an inſtrument uſed by gold-wire-drawers; ſo called from the agate in the middle of it, which forms its principal part.

AGATY, the name of a mallaber tree of the kidney bean ſpecies.

AGAVE, the common American aloe: a genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 10th order, *Coronariæ*. For its characters ſee Syſtem of BOTANY.

Of the Americana, or great American aloe, the ſtems generally riſe upwards of 20 feet high, and branch out on every ſide towards the top, ſo as to form a kind of pyramid: the ſlender ſhoots being garniſhed with greeniſh yellow flowers, which ſtand erect, and come out in thick cluſters at every joint: theſe make a fine appearance, and continue long in beauty; a ſucceſſion of new flowers being produced for near three months in favourable ſeaſons, if the plant is protected from the autumnal colds. The ſeeds do not ripen in England. It has been generally thought, that theſe plants do not flower till they are 100 years old: but this is a miſtake; for the time of their flowering depends on their growth: ſo that in hot countries, where they grow faſt, and expand many leaves every ſeaſon, they will flower in a few years; but in colder climates, where their growth is ſlow, it will be much longer before they ſhoot up their ſtem. There is a variety of this ſpecies with ſtriped leaves, which are pretty common in the Engliſh gardens. The other ſorts are ſo tender, that they muſt conſtantly remain in the ſtove.

AGE, in the moſt general ſenſe of the word, ſignifies the duration of any being, from its firſt coming into exiſtence to the time of ſpeaking of it, if it ſtill continues; or to its deſtruction, if it has ceaſed to exiſt ſome time before we happen to mention it.

Among the ancient poets, this word was uſed for the ſpace of thirty years; in which ſenſe, *age* amounts to much the ſame with *generation.* Thus, Neſtor is ſaid to have lived *three ages* when he was 90 years old. By ancient Greek hiſtorians, the time elapſed ſince the beginning of the world is divided into three periods, which they called *ages.* The firſt reaches from the creation to the deluge which happened in Greece during the reign of Ogyges; this they called the *obſcure* or *uncertain* age, becauſe the hiſtory of mankind is altogether uncertain during that period. The ſecond they call the *fabulous* or *heroic* age, becauſe it is the period in which the fabulous exploits of their gods and heroes are ſaid to have been performed. It began with the Ogygian deluge, and continued to the firſt Olympiad; where the third or *hiſtorical* age commenced. This diviſion, however, it muſt be obſerved, holds good only with regard to the Greeks and Romans, who had no hiſtories earlier than the firſt Olympiad; the Jews, Egyptians, Phenicians, and Chaldees, not to mention the Indians and Chineſe, who pretended to much higher antiquity, are not included in it.

The time ſince the firſt formation of man has been divided by the poets into four *ages*, diſtinguiſhed by the epithets of *golden*, *ſilver*, *brazen*, and *iron.* During the *golden* age, Saturn was ſuppoſed to reign in heaven, and juſtice and innocence in this lower world. The earth then yielded her productions without culture; men held all things common, and lived in perfect friendſhip. This period is ſuppoſed to have laſted till the expulſion of Saturn from his kingdom. The *ſilver* age commenced when men began to deviate from the paths of virtue; and in conſequence of this deviation, their lives became leſs happy. The *brazen* age commenced on a farther deviation, and the *iron* age took place in conſequence of one ſtill greater. A late author, however, reflecting on the barbariſm of the firſt ages, will have the order which the poets aſſign to the four ages inverted; the firſt being a time of rudeneſs and ignorence, more properly denominated an *iron* than a *golden* age. When cities and ſtates were founded, the *ſilver* age commenced: and ſince arts and ſciences, navigation and commerce, have been cultivated, the *golden* age has taken place.

In ſome ancient northern monuments, the *rocky* or *ſtony* age correſponds to the *brazen* age of the Greeks. It is called *rocky*, on account of Noah's ark, which reſted on mount Ararat; whence men were ſaid to be deſcended or ſprung from mountains: or from Deucalion and Pyrrha reſtoring the race of mankind, by throwing ſtones over their heads. The northern poets alſo ſtyle the fourth age of the world the *aſhen* age, from a Gothic king Madenis, or Mannus, who on account of his great ſtrength, was ſaid to be made of aſh, or becauſe in his time people began to make uſe of weapons made of that wood.

Among the Jews, the duration of the world is alſo divided into three ages. 1. The *ſeculum inane*, or *void age*, was the ſpace of time from the creation to Moſes. 2. The *preſent* age, denotes all the ſpace of time from Moſes to the coming of the Meſſiah; and, 3. The *age to come*, denotes the time from the coming of the Meſſiah to the end of the world.

Various other diviſions of the duration of the world into *ages* have been made by hiſtorians. The Sibyline oracles, wrote according to ſome, by Jews acquainted with the prophecies of the Old Teſtament, divide the duration of the world into ten *ages*; and according to Joſephus, each age contained ſix hundred years. It appears, by Virgil's fourth eclogue, and other teſtimonies, that the age of Auguſtus was reputed the end of thoſe ten *ages*, conſequently as the period of the world's duration.

By ſome, the ſpace of time commencing from Conſtantine, and ending with the taking of Conſtantinople by the Turks in the 15th century, is called the *middle age*; but others chooſe rather to date the middle age from the diviſion of the empire made by Theodoſius at the cloſe of the 4th century, and extend it to the time of the emperor Maximilian I. in the beginning of the 16th century, when the empire was firſt divided into circles. The *middle* is by ſome denoted the *barbarous* age, and the latter part of it the *loweſt* age. Some divide it into the *non-academical* and *academical* ages. The firſt includes the ſpace of time from the 6th to the 9th centuries, during which ſchools or academies were loſt in Europe. The ſecond from the 9th century, when ſchools were reſtored, and univerſities eſtabliſhed, chiefly by the care of Charlemagne.

The ſeveral *ages* of the world may be reduced to three grand epochas, viz. the *age* of the law of nature, called by the Jews the *void age*, from Adam to Moſes; the *age* of the Jewiſh law, from Moſes to Chriſt; and the *age* of grace, from Chriſt to the preſent year.

AGE is alſo frequently uſed in the ſame ſenſe with *century*, to denominate a duration of 100 years.

AGE likewiſe ſignifies a certain period of the duration of human life; by ſome divided into four ſtages, namely, infancy, youth, manhood, and old age; the firſt extending to the 14th year, the ſecond to the 25th, the third to the 50th, and the fourth to the end of life: by others divided into infancy, childhood, youth, manhood, and old age.

AGE, in law, ſignifies a certain period of life, when perſons of both ſexes are enabled to do certain acts. Thus, one at twelve years of age ought to take the oath of allegiance to the king in a leet; at fourteen he may marry, chuſe his guardian, and claim his lands held in ſoccage. Twenty-one is called *full-age*, a man or woman being then capable of acting for themſelves, of managing their affairs, making contracts, diſpoſing of their eſtates, and the like.

AGE *of Trees.* Theſe after a certain age waſte. An oak at an hundred years old ceaſes to grow. The uſual rule for judging of the *age* of wood, is by the number of circles which appear in the ſubſtance of a trunk or ſtock cut perpendicularly, each circle being ſuppoſed the growth of a year: though ſome reject this method as precarious, alledging, that a ſimple circle is ſometimes the produce of ſeveral years; beſides that, after a certain age, no new circles are formed.

AGE-*prier*, in law, is when an action being brought againſt a perſon under age, for lands deſcended to him, he, by motion or petition, ſhews the matter to the court, praying the action may be ſtaid till his full age, which the court generally agrees to.

AGEMA, in Macedonian antiquity, was a body of ſoldiery, not unlike the Roman legion.

AGEMOGLANS, AGIAMOGLANS, or AZAMOGLANS, in the Turkiſh polity, are children purchaſed from the Tartars, or raiſed every third year, by way of tribute, from the Chriſtians tolerated in the Turkiſh empire. Theſe, after being circumciſed and inſtructed in the religion and language of their tyrannical maſters, are learnt the exerciſes of war, till they are of a proper age for carrying arms; and from this corps the Janiſſaries are recruited. With regard to thoſe who are thought unfit for the army, they are employed in the loweſt offices of the ſeraglio. Their appointments alſo are very ſmall, not exceeding ſeven aſpers and a half per day, which amount to about three-pence halfpenny of our money.

AGENDA, among philoſophers and divines, ſignifies the duties which a man lies under an obligation to perform: thus, we meet with the *agenda* of a chriſtian, or the duties he ought to perform; in oppoſition to the *credenda*, or things he is to believe.

AGENDA, among merchants, a term ſometimes uſed for a memorandum-book, in which is ſet down all the buſineſs to be tranſacted during the day, either at home or abroad.

AGENDA, among eccleſiaſtical writers, denotes the ſervice or office of the church. We meet with *agenda matutina & veſpertina*, "morning and evening prayers;" *agendi diei*, "the office of the day," whether feaſt or faſt day; *agenda mortuorum*, called alſo ſimply *agenda*, "the ſervice of the dead."

AGENDA is alſo applied to certain church-books, compiled by public authority, preſcribing the order and manner to be obſerved by the miniſters and people in the principal ceremonies and devotions of the church. In which ſenſe, *agenda* amounts to the ſame with what is otherwiſe called *ritual*, *liturgy*, *acalouthia*, *miſſal*, *formulary*, *directory*, &c.

AGENHINE, in our old writers, ſignifies a gueſt that has lodged at an inn for three nights, after which time he was accounted one of the family; and if he offended the king's peace, his hoſt was anſwerable for him.

AGENORIA, in mythology, the goddeſs of courage and induſtry, as *Vacuna* was of indolence.

AGENT, in a general ſenſe, denotes any active power or cauſe. Agents are either natural or moral. Natural agents are ſuch inanimate bodies as have a power to act upon other bodies in a certain and determinate manner; as, gravity, fire, &c. Moral agents, on the contrary, are rational creatures, capable of regulating their actions by a certain rule.

AGENT is alſo uſed to denote a perſon intruſted with the management of an affair, whether belonging to a ſociety, company, or private perſon.

AGENTES *in rebus*, one of the ranks of officers in the court of the Conſtantinopolitan emperors, whoſe buſineſs was to collect and convey the corn both for the army and houſhold; to carry letters and meſſages from court to all parts of the empire; to regulate couriers, and their vehicles; to make frequent journeys and expeditions through the provinces, in order to inſpect any motions, diſturbances, or machinations tending that way, and to give early notice thereof to the emperor.

The *agentes in rebus*, are by ſome made ſynonymous with our poſt-maſters, but their functions were of great extent. They correſpond to what the Greeks call ϖυροφοροι, and the Latins *veredarii*.

There were various orders or degrees of *agentes in rebus*; as, *tribuni, primicerii, ſenatores, ducenarii, biarchi, circitores, equites, tyrones*, &c. through all which they roſe *gradatim*. Their chief, who reſided at Conſtantinople, was denominated *princeps*; which was a poſt of great dignity, being reckoned on a level with that of proconſul. They were ſettled in every part of the empire; and are alſo ſaid to have ſerved as interpreters.

AGER, in Roman antiquity, a certain portion of land allowed to each citizen.

AGERATUM, BASTARD HEMP-AGRIMONY: a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ diſcoides*. For the characters, ſee Syſtem of BOTANY.

AGEROMETRIA, implies a deviation from the two principles of Geometry.

AGGADA, in Jewiſh antiquity, an ingenious tale, or ſtory; of which kind there are many in the Talmud. There are ſeveral books extant among the Jews under this title.

AGGER, in the ancient military art, a work of fortification, uſed both for the defence and the attack of towns, camps, &c. In which ſenſe it is the ſame with what was otherwiſe called *vallum*, and in later times *aggeſtum*: and among the moderns *lines*, ſometimes *cavaliers, terraſſes*, &c.

AGGER, in ancient writers, likewiſe denotes the middle part of a military road, raiſed into a ridge, with a gentle ſlope on either ſide, to make a drain for the water, and keep the way dry. The term is alſo uſed for the whole road, or military way. Where highways were to be made in low grounds, as between two hills, the Romans uſed to raiſe them above the adjacent land, ſo as to make them of a level with the hills. Theſe banks they called *aggeres*. Bergier mentions ſeveral in Gallia Belgica, which were thus raiſed ten, fifteen, or twenty feet above ground. They are ſometimes alſo called *aggeres calceati*; and now generally known by the name *chauſſees*, or *cauſeways*.

AGGLUTINANTS, in pharmacy, a general name for all medicines of a glutinous or viſcid nature; which, by adhering to the ſolids, contribute greatly to repair the loſs.

AGGLUTINATIO PILORUM, reducing the hairs of the eye-lids that grow inwards to their natural order and ſituation. This may be done by maſtic, applied with a probe, which bends the hairs back into their proper order.

AGGLUTINATION, in a general ſenſe, denotes the joining two or more things together, by means of a proper glue or cement.

AGGLUTINATION, among phyſicians, implies the action of returning the parts of a body, ſeparated by a wound, cut, &c. It is alſo applied to the action of ſuch internal medicines as are of an agglutinating quality, and which, by giving a glutinous conſiſtance to the animal-fluids, render them more proper for nouriſhing the body.

AGGREGATE, in a general ſenſe, denotes the ſum of ſeveral things added together, or the collection of them into one whole. Thus, a houſe is an aggregate of ſtones, wood, mortar, &c. It differs from a mixed or compound, inaſmuch as the union of theſe laſt is more intimate than between the parts of an aggregate.

AGGREGATE, in botany, is a term uſed to expreſs thoſe flowers, which are compoſed of parts or florets, ſo united by means either of the receptacle or calyx, that no one of them can be taken away without deſtroying the form of the whole. They are oppoſed to ſimple flowers, which have no ſuch common part, and are uſually divided into ſeven kinds, viz. the *aggregate*, properly ſo called, whoſe receptacle is dilated, and whoſe florets are ſupported by foot-ſtalks; ſuch are the blue daiſy, thrift, or ſea-pink, &c. the *compound*; the *umbellati*; the *cymoſe*; the *amentaceus*; the *glumoſe*; and the *ſpadiceous*.

AGGREGATION, in phyſics, a ſpecies of union whereby ſeveral things which have no natural dependence or connection with one another are collected together, ſo as in ſome ſenſe to conſtitute one. Thus a heap of ſand, or a maſs of ruins, are bodies by aggregation.

AGGRESSOR, in law, the firſt offender in any caſe where an action lies, whether civil or criminal.

AGGREVATION, the act of augmenting a crime, or the puniſhment due to it.

AGIADES, in the Turkiſh armies, a kind of pioneers employed in fortifying camps, ſmoothing of roads, and the like offices.

AGIAHALID, the name of an Egyptian tree, called alſo *licio* and *lycium*: it reſembles the wild pear.

AGILD, or AGILDE, in our antient cuſtoms, a perſon ſo vile that whoever killed him was to pay no mulct for his death.

AGILENOZ, in botany, a name uſed, by ſome, for the common hazel.

AGILITY, an aptitude of the ſeveral parts of the body to motion. The improving of agility was one of the chief objects of the inſtitution of games and exerciſes. The athletæ made particular profeſſion of the ſcience of cultivating and improving agility. Agility of body is often ſuppoſed peculiar to ſome people; yet it ſeems leſs owing to any thing peculiar, in their frame and ſtructure, than to practice.

AGILITY, in a grammatical ſenſe, implies a nimbleneſs of action.

AGILLAMIS, in ancient law, implied a herdſman, or keeper of cattle in an open unfenced field.

AGIO, in commerce, is a term chiefly uſed in Holland, and at Venice, to ſignify the difference between the value of bank-ſtock and the current coin. The agio in Holland is generally three or four per cent. and at Rome it is from 15 to 25 per cent. but at Venice the agio is fixed at 20 per cent.

AGIOSYMANDRUM, a wooden inſtrument uſed by the Greek and other churches under the dominion of the Turks, to call together aſſemblies of the people. The *agioſymandrum* was introduced in the place of bells, which the Turks prohibited their Chriſtian ſubjects the uſe of, leſt they ſhould make them ſubſervient to ſedition.

AGISTMENT, AGISTAGE, or AGISTATION, in law, the taking in other people's cattle to graze at ſo much per week. The term is peculiarly uſed for the taking cattle to feed in the king's foreſts, as well as for the profits ariſing from that practice. It is alſo uſed, in a metaphorical ſenſe, for any tax, burden, or change; thus, the tax levied for repairing the banks of Romney-marſh was called *agiſtamentum*.

AGISTOR, or AGISTATOR, an officer belonging to foreſts, who has the care of cattle taken in to be grazed, and levies the moneys due on that account. They are generally called *queſt-takers*, or *giſt-takers*, and are created by letters-patent. Each royal foreſt has four agiſtors.

AGITATION, the act of ſhaking a body, or toſſing it backwards and forwards.

AGITATION, in phyſics, is often uſed for an inteſtine commotion of the parts of a natural body. Fermentation and efferveſcence are attended with a briſk agitation of the particles.

AGITATION is reputed one of the ſymptoms of inſpiration. Petit informs us, that, in the laſt century, there aroſe in a church in Italy, for the ſpace of a year, a vapour of an extraordinary kind, which put all the people into trembling and agitations, and unleſs they got away betimes, ſet them a dancing, with ſtrange contortions and geſticulations. This ſeems to verify what has been related of the temple of Delphi.

AGITATION is alſo uſed in medicine for a ſpecies of exerciſe generally called *ſwinging*. Maurice, prince of Orange, found this method a relief againſt the ſevere pains of the gout and ſtone. Bartholine mentions fits of the tooth-ach, deafneſs, &c. removed by vehement agitations of the body.

AGITATOR, in antiquity, a term ſometimes uſed for a charioteer, eſpecially thoſe who drove in the circus at the curule games.

AGITATORS, in the Engliſh hiſtory, certain officers ſet up by the army in 1647, to take care of its intereſts. Cromwell joined the agitators, only with a view to ſerve his own ends; which being once accompliſhed, he found means to get them aboliſhed.

AGLAIA, the name of the youngeſt of the three graces, eſpouſed to Vulcan.

AGLAOPHOTIS, in botany, the ſame as piony.

AGLECTS, amongſt floriſts, implies the pendants of flowers.

AGLIA, in phyſic, ſignifies a ſpot on the pupil of the eye.

AGME, in ſurgery, implies a fracture.

AGMEN, in antiquity, properly denotes a Roman army in march: in which ſenſe, it ſtands contradiſtinguiſhed from *acies*, which denoted the army in battle array; though, on ſome occaſions, we find the two words uſed indifferently for each other. The Roman armies, in their marches, were divided into *primum agmen*, anſwering to our vanguard; *medium agmen*, our main-battle; and *poſtremum agmen*, the rear-guard. The order of their march was thus: After the firſt ſignal with the trumpets, &c. the tents were taken down, and the baggage packed up; at the ſecond ſignal, the baggage was to be loaden on the horſes and carriages; and at the third ſignal, they were to begin their march. Firſt came the *extraordinarii*; then the auxiliaries of the firſt wing, with their baggage; theſe were followed by the legions. The cavalry marched either on each ſide or behind.

AGNATE, in law, any male relation by the father's ſide.

AGNEL, an ancient French gold coin, firſt ſtruck under the reign of St. Louis, worth about twelve ſols ſix deniers. The agnel is alſo called ſometimes *mouton d'or*, and *agnel d'or*. The denomination is ſuppoſed to have ariſen from the figure of a lamb, agnus, or ſheep, ſtruck on one ſide.

AGNOETÆ, from αγνοεω, to be *ignorant* of, in church-hiſtory, a ſect of ancient heretics, who maintained that Chriſt, conſidered as to his human nature, was ignorant of certain things, and particularly of the time of the day of judgment. Eulogius, patriarch of Alexandria, aſcribes this hereſy to certain ſolitaries in the neighbourhood of Jeruſalem, who built their opinion upon the text Mark xiii. 32. "Of that day and hour knoweth no "man, no not the angels who are in heaven, neither the Son, "but the Father only." The ſame paſſage was made uſe of by the Arians; and hence the orthodox divines of thoſe days were induced to give various explications thereof. Some alledge, that our Saviour here had no regard to his divine nature, but only ſpoke of his human. Others underſtand it thus, That the knowledge of the day of judgment does not concern our Saviour conſidered in his quality of Meſſiah, but God only: which is the moſt natural ſolution.

AGNOMEN, in Roman antiquity, a kind of fourth or honorary name, given to a perſon on account of ſome extraordinary action, virtue, or other accompliſhment. Thus the agnomen Africanus was beſtowed upon Publius Cornelius Scipio, on account of his great atchievements in Africa. The agnomen was the third in order of the three Roman names: thus, in Marcus Tullius Cicero, Marcus is the prænomen, Tullius the nomen, and Cicero the agnomen.

AGNUS, or Lamb, in zoology, the offspring of the ovis or ſheep.

Agnus *Caſtus*, in botany, the trivial name of a ſpecies of the vitex. See Vitex. The Greeks call it *αγνος*, *chaſte*; to which has ſince been added the reduplicative *caſtus*, q. d. chaſte chaſte. It was famous among the ancients as a ſpecific for the preſervation of chaſtity. The Athenian ladies, who made profeſſion of chaſtity, lay upon leaves of *agnus caſtus* during the feaſts of Ceres.

Agnus *Dei*, in the church of Rome, a cake of wax ſtamped with the figure of a lamb ſupporting the banner of the croſs. Theſe being conſecrated by the pope with great ſolemnity, and diſtributed among the people, are ſuppoſed to have great virtues; as, to preſerve thoſe who carry them worthily, and with faith, from all manner of accidents; to expel evil ſpirits, &c. The name literally ſignifies *Lamb of God*; this being ſuppoſed an image or repreſentation of the Lamb of God who took away the ſins of the world. They cover it up with a piece of ſtuff cut in form of a heart, and carry it very devoutly in their proceſſions. The Romiſh prieſts and religious derive conſiderable pecuniary advantage from ſelling theſe *Agnus Dei's* to ſome, and preſenting them to others. The pope provides a regular ſupply, by conſecrating once in ſeven years; they are diſtributed by the maſter of the wardrobe, and received by the cardinals and other prelates, with great reverence, in their caps and mitres. This ceremony they pretend to derive from an ancient cuſtom of the church, wherein part of the paſchal taper conſecrated on Holy Thurſday was diſtributed among the people, to perfume their houſes, fields, &c. in order to drive away devils, and to preſerve them from ſtorms and tempeſts. The *Agnus Dei* is forbidden to be brought into England under pain of incurring a *premunire*. See Stat. 13 Eliz. cap. 2.

Aguts *Dei* is alſo a popular name for that part of the maſs wherein the prieſt, ſtriking his breaſt three times, rehearſes, with a loud voice, a prayer beginning with the words *Agnus Dei*. The *Agnus Dei* is ſaid to have been firſt brought into the miſſal by pope Sergius I.

AGOGE, among ancient muſicians, a ſpecies of modulation, wherein the notes proceed by contiguous degrees.

AGON, among the ancients, implied any diſpute or conteſt, whether it had regard to bodily exerciſes or the accompliſhments of the mind; and therefore poets, muſicians, painters, &c. had their agones, as well as the athletæ. Games of this kind were celebrated at moſt of the heathen feſtivals, with great ſolemnity, either annually, or at certain periods of years. Among the latter were celebrated at Athens, the *agon gymnicus*, the *agon nemeus* inſtituted by the Argives in the 53d Olympiad, and the *agon Olympius* inſtituted by Hercules 430 years before the firſt Olympiad. The Romans alſo, in imitation of the Greeks, inſtituted conteſts of this kind. The emperor Aurelian eſtabliſhed one under the name of *agon ſolis*, the conteſt of the ſun; Diocleſian another, which he called *agon capitolinus*, which was celebrated every fourth year, after the manner of the Olympic games. Hence the years, inſtead of *luſtra*, are ſometimes numbered by *agones*.

Agon alſo ſignified one of the miniſters employed in the heathen ſacrifices, and whoſe buſineſs it was to ſtrike the victim. The name is ſuppoſed to have been derived from hence, that ſtanding ready to give the ſtroke he aſked, *Agon?* or *Agone?* Shall I ſtrike?

AGONALES, an epithet given to the Salii.

AGONALIA, in Roman antiquity, feſtivals celebrated in honour of Janus, or the god Agonius, whom the Romans invoked before undertaking any affair of importance.

AGONISMA, in antiquity, denotes the prize given to the victor in any combat or diſpute.

AGONISTARCHA, from *αγων* "combat," and *αρχος* "chief," in antiquity, ſeems to have been much the ſame with *agonotheta*; though ſome ſuggeſt a difference, making it the office of the former to preſide at and direct the private exerciſes of the athletæ, which they went through by way of practice, before they made their grand appearance on the public theatres or amphitheatres.

AGONISTICI, in church-hiſtory, a name given by Donatus to ſuch of his diſciples as he ſent to fairs, markets, and other public places, to propagate his doctrine; for which reaſon they were alſo called *Circuitores*, *Circelliones*, *Catropitæ*, *Coropitæ*, and at Rome *Montenſes*. They were called *Agoniſtici*, from the Greek *αγων*, "combat," in regard they were ſent as it were to fight and ſubdue the people to their opinions.

AGONIUM, in Roman antiquity, was uſed for the day on which the *rex ſacrorum* ſacrificed a victim, as well as for the place where the games were celebrated, otherwiſe called *agon*.

AGNOTHETA, or Agnothetes, in Grecian antiquity, was the preſident or ſuperintendant of the ſacred games; who not only defrayed the expences attending them, but inſpected the manners and diſcipline of the athletæ, and adjudged the prizes to the victors.

AGONY, any extreme pain. It is alſo uſed for the pangs of death. Much of the terror of death conſiſts in the pangs and convulſions wherewith the agony ſeems attended; though we have reaſon to believe that the pain in ſuch caſes is ordinarily not extremely acute; a courſe of pain and ſickneſs having uſually ſtupified and indiſpoſed the nerves for any quick ſenſations. However, various means have been thought of for mitigating the agony of death. Lord Bacon conſiders this as part of the province of a phyſician; and that not only when ſuch a mitigation may tend to a recovery, but alſo when, there being no further hopes of a recovery, it can only tend to make the paſſage out of life more calm and eaſy. Complacency in death, which Auguſtus ſo much deſired, is certainly no ſmall part of happineſs. Accordingly the author laſt cited ranks *euthanaſia*, or the art of dying eaſily, among the deſiderata of ſcience; and does not even ſeem to diſapprove of the courſe Epicurus took for that end,

—— *Hinc ſtygias ebrius hauſit aquas.*

Opium has been applied for this purpoſe, with the applauſe of ſome, but the condemnation of more.

AGONYCLITÆ, or Agonyclites, in church-hiſtory, a ſect of chriſtians, in the 7th century, who prayed always ſtanding, as thinking it unlawful to kneel.

AGORÆUS, in heathen antiquity, an appellation given to ſuch deities as had ſtatues in the market-places; particularly Mercury, whoſe ſtatue was to be ſeen in almoſt every public place.

AGORANOMUS, in Grecian antiquity, a magiſtrate of Athens, who had the regulation of weights and meaſures, the prices of proviſions, &c. The *agoranomi*, at Athens, were ten in number, five belonging to the city, and as many to the Piræus; though others make them fifteen in all, of whom they aſſign ten to the city. To theſe a certain toll or tribute was paid, by all who brought any thing to ſell in the market.

AGRARIAN Laws, among the Romans, thoſe relating to the diviſion and diſtribution of lands, of which there were a great number; but that called the Agrarian law, by way of eminence, was publiſhed by Spurius Caſſius, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres which each citizen might enjoy. The Roman lands were of ſeveral kinds; ſome conquered from the enemies, and not yet brought to the public account; others brought indeed to the public, but clandeſtinely uſurped by private great men; laſtly, others purchaſed with the public money, in order to be divided. Agrarian laws, either for dividing lands taken from the enemy, or the public lands, or thoſe purchaſed with the public money, were eaſily paſſed without diſturbance; but thoſe whereby private rich men were to be deprived of their lands, and the common people put in poſſeſſion of what had been held by the nobility, were never attempted without great diſturbances.

Several have pleaded for the neceſſity of Agrarian laws among us: but no author has entered ſo deeply into the ſubject as Mr. Harrington in his *Oceana*; which the reader who chooſes may conſult.

AGREEMENT, in law, the act whereby any two or more parties come to a final concluſion, by determining upon the points in diſpute to the ſatisfaction of each of them.

AGRESSES, in heraldry, the ſame as pellets.

AGRESSTA, in medicine, ſignifies an unripe or green grape, when applied as a cooler to the animal ſyſtem.

AGRIÆ, in natural hiſtory, implies the quadruped race which have no teeth, but have a very long cylindrical tongue.

AGRIAMPELOS, the wild vine, the production of the Aſiatic iſlands.

AGRICULTURE, in a general ſenſe, implies the art of tilling the ground, ſo as to render it fruitful; whether manuring, fallowing, ſowing, harrowing, reaping, mowing, &c. the management of the productions of different ſoils, and planting; together with the culture of foreſts, timber, &c.

The following Syſtem of Agriculture is the production of a gentleman, a practical farmer of Oxfordſhire, which I have peruſed with great attention, and conſider myſelf as highly indebted to him for his judicious treatiſe. It is a production which, I am convinced, will afford both entertainment and utility to the public, it being abridged of all that ſuperfluous theory and redundancy, which cannot be reduced to practice; and, from the preſcribed compaſs in which it is confined, from the nature of the work, I will preſume to denounce it the moſt complete Syſtem of Agriculture ever yet preſented to the public.

W. H. HALL.

A NEW SYSTEM of AGRICULTURE.

AS we commenced our undertaking with the intention of pruning Art and Science of that burthen of uſeleſs theory, with which other ſimilar publications have been loaded, we ſhall endeavour to collect, from the beſt information, ſuch theory as is conſiſtent with practice, and ſuch practice as we have known tried and approved.

In the important Art of Agriculture, now before us, moſt writers on the ſubject have been men of independent fortunes, making experiments in gardens and other ſmall, rich incloſures; and, on a favourable reſult, have committed their thoughts to the public as unerring maxims; not conſidering the expence, or the practicability of their ſchemes on a larger ſcale or inferior ſoil.

The more ſimple the plan of huſbandry, the more certain will be the farmer's ſucceſs; it being almoſt without a precedent that a book-learned farmer ever became wealthy; for which we can aſſign no other reaſon, than that former theories, being compoſed of undigeſted, ſpeculative materials, ſerve only to perplex, inſtead of inſtruct, the practitioner, who depends on them for knowledge.

Theſe are not the only defects to which lettered huſbandmen have been ſubject, and the compilers of dictionaries have copied, from whence every modern treatiſe on the ſubject is rendered unintelligible to a majority of thoſe whom it materially concerns, by being filled with pedantic terms of art, or, on the other hand, with provincial dialect.

We ſhall not fill page after page with the errors and inconſiſtencies of other writers, thinking it ſufficient to paſs them over with that diſregard they deſerve; and that our readers are entitled to ſomething of more intrinſic value, than Mr. Young's account of "feeding a lean hog fat in ten days with carrots;" and other miracles ſo frequently to be met with in the works of thoſe ſcientific writers. Where we meet with ingenious theory that claſhes with practice, we beg leave, with all ſubmiſſion, to adopt the idea, at the ſame time making due acknowledgment to whom we are indebted; and occaſionally we ſhall take the liberty to expoſe abſurdities, as we think the labours of others, as well as our own, lie open to candid criticiſm.

Hiſtory and Progreſs of Agriculture.

Agriculture unqueſtionably has been practiſed in the moſt remote ages of the world. As mankind advanced from a ſtate of nature their neceſſities increaſed, and invention made improvements on ſpontaneous vegetation.

The mode of cultivation uſed in the antediluvian world we muſt leave to the inveſtigation of thoſe who are reſolved to ſay ſomething on every ſubject, and, rather than be ſilent, fill up the chaſm with idle conjecture. The works of Heſiod and Virgil can add nothing to a ſyſtem of Britiſh huſbandry, although they abound with fine imagery, and, perhaps, the firſt information, the ſubject was capable of receiving, when practiſed in the warm luxuriant climate of Italy, where oil and wine are produced without human aid.

Leaving this unintereſting detail to thoſe we endeavour to amuſe, inſtead of inſtruct, we proceed to give a conciſe narrative of the progreſs of agriculture in our own country, where the hand of nature has been very ſparing of her gifts, as few of the neceſſaries of life flouriſh without the moſt unremitted induſtry. By nature our apples are crabs, and our plums, ſloes; but art and labour have changed the ſcene, and health-giving exerciſe has brought this kingdom to an unequalled ſituation of plenty and ſplendor.

The æra when the yeomanry of England, in a great meaſure, began to feel the benign effects of freedom, was in the reign of Henry VIII. after the diſſolution of the monaſteries; the heavy yoke of church tyranny being removed, all degrees of people, from the peaſant to the peer, began to ſee the happy effects of cultivation. Several acts of parliament were then paſſed for incloſing of waſte lands, improving the breed of cattle, and other good purpoſes, all which ſhew how highly, and of what importance, the legiſlature thought Agriculture.

It is evident that at this time tillage was extended as wide as it poſſibly could be, and manures, except the produce of the fold and ſtable, but little known, or, from the badneſs of roads, were but ſeldom applied. Moſt of the wood lands in the inland parts of the kingdom bear evident traces of the plough, which are now occupied by venerable decaying oaks, in all probability of three or four hundred years ſtanding. There are but few downs or ſheep walks that have not the marks of cultivation; but neither memory or tradition account for the time when they were in that ſtate. The grain produced at that time was the ſame as the preſent, except a much greater portion of rye, then almoſt in general uſe for bread, either alone or mixed with wheat. Saintfoin was introduced into England previous to this period, as alſo clover; but the value of artificial graſſes, or roots, for the ſupport of cattle, and improvement of land, were not in practice. Implements of huſbandry were very heavy and cumbrous, but nearly of the ſame principle as at preſent.

Dividing and incloſing waſte and commonable lands continued till the reign of Edward VI. when improvement received a very ſevere check; a number of perſons riotouſly aſſembled in various parts of the kingdom, and, by pulling up the fences, laid waſte, and deſpoiled, what induſtry and judicious management had effected. We may, from this circumſtance, infer, that incloſures were not conducted in that equitable and juſt manner as they are at the preſent day. A mob have generally ſome pretence for their conduct, and in the preſent inſtance the lower order of people, finding their property invaded, had recourſe to thoſe violent means for redreſs. This and the troubled ſtate of the nation rendered improvements in agriculture very ſlow in their progreſs during the troubleſome reign of Queen Mary and the former part of that of Elizabeth.

Fitzherbert, judge of the Common Pleas in the year 1525, was the firſt perſon who wrote on the ſubject of Agriculture in England, and whoſe familiar ſtile is a proof that he meant to ſerve the cauſe. His excellent inſtructions reſpecting the management of land and of cattle render him one of the greateſt ornaments of the age in which he lived. For the entertainment and information of our readers we give them a ſpecimen of his works in their native dreſs.

Directions to be obſerved in the choice of lean cattle for feeding, as well as thoſe which are already fat.

> " Theſe huſbandes and they that wyl thryve they
> " muſt have both kie, oxen, horſes, mares, and yong
> " cattel, and to reyre and brede every yere ſome calves
> " and foles, or els ſhal he be a byer. And if thou ſhalt
> " bie oxen for the plough, ſe that they be yonge and
> " nat gouty, nor broken of heare nother of tayle, nor
> " of pyſel. And if thou bye kye to the payle, ſe that
> " they be yong and good to mylke, and fede her calfes
> " wel. And yf thou bye keye or oxen to fede, the
> " yonger they be the rather they wyl fede, but loke wel
> " that the heare ſtare nat, and that he lycke him ſelfe,
> " and be whole mouthed, and want no teth. And
> " though he haue the goute, and be broken both of
> " tayle and pyſel, yet wyl he fede. But the gouty oxe
> " wyl nat be driuen far, and ſe that he haue a brode
> " ribbe and a thicke hyde, and to be louſe ſkinned, that
> " it ſticke nat harde nor ſtrait to his ribbes, for then he
> " will nat fede.
>
> " And yf thou ſhalt bye fat oxen or kye, handle them
> " and ſe that they be ſofte on the fore crop behynde the
> " ſhoulder and upon the hyndermoſt ryb and vpon the
> " hucklebone, and the nach by the tayle. And ſe the
> " oxe haue a great cod and the cowe a great nauyl, for
> " then it ſhulde ſeme that they ſhuld be wel talowed.
> " And take hede wher thou byeſt any leane cattel or fat,
> " and of whom, and wher it was bred; for yf thou bye
> " out of a better grounde then thou haſt thy ſelfe, that
> " cattel wyl nat lyke with the. Alſo loke that there be
> " no mener of ſicknes among the cattel in that towneſhyp
> " or paſture that thou byeſt thy cattel out of. For
> " if there be any murren or longſought, it is great
> " ieopardy, for a beaſt may take ſicknes ten or twelve
> " dayes or more, or it appere on him."

The practical directions given in this ſhort extract are alone ſufficient to prepoſſeſs every huſbandman in this good judge's favour. What grazier would wiſh for more wholeſome advice?

Sir Francis Bacon threw in his mine of philoſophy at this period. What art or ſcience was there this great genius did not illuminate?

A north-countryman of the name of Lawſon alſo employed his ruſtic pen, and although his writings contain a number of abſurdities, yet he frequently acquits himſelf like a farmer.

Several tranſlations from the French and other languages made their appearance about this time, containing ſo little to the purpoſe that it is obvious this country poſſeſſed a ſuperiority in Agriculture even at this period.

The celebrated botaniſt Gerrard publiſhed his great work about the latter end of the reign of Elizabeth, and was the firſt who taught the culture of potatoes. If we conſider the period at which Gerrard wrote, his voluminous publication, with the correctneſs and beauty of his work, we cannot withhold our aſtoniſhment at his unrivalled merits and induſtry.

From the beginning of James I. to the end of Charles I. little reſpecting huſbandry can be collected, every manœuvre was uſed and every opportunity taken by thoſe kings and their adherents to increaſe the prerogative of the crown: the event that followed need not be mentioned here; but we cannot help remarking, that when monarchial government ceaſed, art and induſtry rapidly improved, particularly ſcientific and practical Agriculture.

The writings of Sir Hugh Platt deſerve every praiſe, and prove him a man actuated by the pureſt of motives, the good of his country. Gabriel Plattes muſt likewiſe have made cultivation his principal ſtudy, as his writings conſiſt of ſeveral digreſſions, and good practical information.

But of all the writers on huſbandry, Captain Blyth ſtands foremoſt. His works in 4to are dedicated to Oliver Cromwell, and furniſh as complete a ſyſtem of practice as ever was produced by an individual. He treats largely on ſoils, and their different management; manures, and how to apply them to the beſt advantage. On the culture of various graſſes now in uſe, (which are generally thought to have been unknown at the period he wrote) alſo on turnips and other roots for the uſe of cattle. The improvement of meadow and paſture lands are, with very few exceptions, the beſt committed to print. Under-draining and cleanſing ſwampy ground were well known to this writer; and altho' the great improvement in draining fens has been ſo recently adopted, Captain Blyth gave a plate and accurate deſcription of engines for that purpoſe, nearly the ſame as thoſe now in uſe. He ſtrongly recommends incloſures, and the planting of coppices and timber, and frequently in a manner that proves him a complete maſter of his ſubject.

Samuel Hartlib lived in intimacy, and correſponded with, the writer before-mentioned, as did the immortal Milton,

During the common-wealth Agriculture flouriſhed, and the huſbandman met with every encouragement a wiſe government could beſtow; and however hiſtorians may brand the rulers of the day with puritanical fanatics, or fanaticiſm, and other opprobrious epithets, it is certain Art and Science flouriſhed, and thoſe who directed the helm of ſtate did not number the acquiſition of wealth among their ambitious purſuits. But this wiſe turn was not of long continuance. At the Reſtoration they generally became infected with that intoxication and love of pleaſure which ſucceeded. All their induſtry and knowledge were exchanged for neglect and diſſipation; and huſbandry deſcended as rapidly as it had lately improved.

Jethro Tull next followed, and endeavoured to cut up the old ſyſtem root and branch, and to introduce in its ſtead drilling and horſe-hoeing, without the uſe of manure. This novel mode has had many advocates, who, with too much credulity, taking Mr. Tull's *ipſe dixit* for matter of fact, have always relinquiſhed the plan, and on conſulting their pockets have found the idea mere quackery. Not that drilling is, in every reſpect, inconſiſtent with practical huſbandry. In many inſtances great good may accrue from the practice, when judiciouſly uſed, on ſome kinds of ſoil; but Mr. Tull and his diſciples, by attempting to make drilling general, have brought it into diſgrace with a great majority of thoſe who have given credit to their aſſertions.

Since the Revolution Agriculture has been materially improved, particularly the culture of graſſes and roots for the uſe of cattle in the winter, and early in the ſpring. Mr. Bradley, profeſſor of Botany in the univerſity of Cambridge, took up the cauſe of agriculture, and his writings on the ſubject do him great credit as a ſcientific and practical author. Mr. William Ellis, of Gadſden in Hertfordſhire, by his writings diſplayed conſiderable knowledge in Agriculture, and was the perſon who firſt made known without reward what Mr. Vagg has lately delivered to the public as his own invention,

Several others of leſs note have wrote on Agriculture; and ſeveral ſocieties have been pompouſly eſtabliſhed, to promote the art; but to writers and ſocieties we will venture to aſſert, a ſmall ſhare of praiſe is due. Improved roads and incloſures are the great ſource of agricultural improvement, and thoſe incloſures particularly which are exonerated from tythes.

The clergy in general are fickle, perhaps more ſo than any other order of ſociety, and nothing but a commutation in lieu of tythes can ſecure a farmer from that moſt unwelcome of all viſitants the tytheman. To toil, invent, and uſe expenſive means to improve land; to improve live ſtock at a great expence, and your neighbour to come and claim a tenth of your induſtry, is, of all taxes, the moſt cruel. Let our readers only weigh the matter one minute. We will ſuppoſe a farmer to cultivate his land nine ſucceſſive years, and to take the produce to his own uſe and benefit, and on the tenth plough and ſow as uſual, increaſe his live ſtock, make the beſt of the dairy, reap and mow, pay ſervants their wages, and every conſequent expence whatever; then comes the clergyman, and takes all the produce, leaving neither hay or corn for cattle, nor any thing to make manure for the ſucceeding years. This is eventually the caſe, by which the farmer is greatly injured, and the proprietor of tythes proportionably benefited.

When tythes are commuted and conſumed on the land where they grow, the farmer collects them without an additional expence, and what is of equal importance his land is not impoveriſhed, by loſing annually one tenth of its produce. The collector of tythes finds himſelf in quite a different predicament, being obliged to keep a team of horſes, and ſervants, to collect tythes over an extenſive pariſh, and when they are collected to draw the corn, &c. to market, and, except there are ſome glebe lands annexed to the living (which is frequently not the caſe, and the quantity always very ſmall) he has no place but a fold yard for the cattle, kept to eat the hay and ſtraw, and cannot diſpoſe of the manure to a proper advantage. Theſe are but few of the diſagreeable circumſtances which attend the collecting of tythes, and which every perſon acquainted with the buſineſs muſt be ſenſible of. The great national importance we conceive of agriculture led us to theſe conciſe obſervations reſpecting incloſures, and the commutation of tythes; being well convinced that was the plan generally adopted, all ranks of people would participate in the advantages; the clergy would become more eſteemed and reſpected, and inſtead of being the authors of feuds and law-ſuits, would have ſeldom reaſon to deviate from thoſe fine examples of their maſter the "MINISTER OF PEACE!"

Within theſe few years it has become a very prevailing idea with gentlemen of large landed property to refuſe leaſes to their tenants, particularly of any long continuance; under the notion that during the term of a leaſe the proprietor is not maſter of his property. If a landlord will aſſiſt his tenants in making improvements, lands may be rendered more fertile without being let on long leaſes, but admitting that to be the caſe, a farmer cannot exerciſe his ſkill and induſtry with that ſpirit which is requiſite in all important undertakings, without ſome probable ſecurity for the enjoyment of the fruits of his labour. In the inſtance before us, where can the tenant fix any hopes of reward! death may perhaps take from him a landlord on whom he could depend, and whoſe word was equal to his bond, and the eſtate devolve to another, who, regardleſs of the promiſe of his predeceſſor, gives his tenant notice to quit, or cruelly raiſes his rent. There is a variety of other cauſes by which a man may be turned out of his farm, before he has reaped any benefit from expenſive improvements—his dog may unfortunately kill a hare which has been bred and nouriſhed on the farm; or the ſame maſtiff may cruelly fall upon and beat a pointer or ſpaniel, when the gentleman his keeper, or ſteward was ſporting on the premiſes. On ſuch accidents as theſe, and others of equal conſequence, we have known gentlemen diſcard their tenants; we have likewiſe known tenants extremely impertinent and overbearing, knowing themſelves ſecure from their landlords reſentment, by having a leaſe of many years unexpired. On briefly conſidering and weighing matters between the leſſor and leſſee, we are well convinced, that a leaſe of not leſs than fourteen years will be of mutual benefit to both parties. And if at the commencement of a new incloſure, or where conſiderable improvements are neceſſary, ſuch leaſe ſhould extend to twenty-one years, otherwiſe the proprietor cannot expect his eſtate will be properly managed and improved, or the tenant will riſque his property and induſtry without a hope on which he can depend of making a return. Preſcribing a ſyſtem of management by leaſe to a tenant is curbing genius and tying the hands of induſtry; the reſult of various ſeaſons, and local circumſtances often require different modes of cultivation: we are ſorry to obſerve ſo impolitic a meaſure, ſo much in vogue amongſt landed gentlemen, being convinced improvements in agriculture are greatly impeded by ſuch means. Some reſtraints are certainly neceſſary, particularly the management of fences, not ſelling manure, or ſuch produce of the land which makes manure, and other ſimilar covenants; but always to enforce one unalterable round of cultivation is making an attorney the practical huſbandman, and the huſbandman of no more conſequence than a horſe in a mill. The three or four laſt years of a leaſe, it is neceſſary for the leſſor to bind the tenant in a particular manner for the benefit of the ſucceeding tenant provided he ſhould change, but enforcing a general ſeries of huſbandry will not improve an ignorant and ſlovenly man, and is ſure to injure him who is ingenious and aſſiduous.

In the choice of a tenant a gentleman ſhould look for a perſon of plain unaffected manners, by no means of a whimſical turn of mind, an early riſer, perſevering, induſtrious and honeſt, bred to and capable of performing all parts of the buſineſs, and poſſeſſed of property equal to the undertaking. Farms ſhould be rented in ſuch a manner, as the cultivator, by hazarding his property and exerciſing his induſtry, ſhould acquire a comfortable ſubſiſtence, and ſomething to render the decline of life pleaſant and happy. When this is the caſe, the landlord and tenant are generally pleaſed to meet each other, whereas on the contrary, a gentleman reluctantly views his own eſtate, as it neither yields him his income at the proper ſeaſon, nor receives that cultivation which he can ſee with pleaſure; for nothing reſtrains aſſiduity ſo much as labouring without a proſpect of gain. You will always perceive a farmer who rents his farm too high, inert and melancholy as a careleſs drunkard.

Mr. Young very juſtly obſerves, "that the cultivation of ſmall farms by their owners is generally productive of the beſt and moſt improveable mode of agriculture, as the farmer finds himſelf doubly encouraged by intereſt." In this, as in a number of other ideas, we perfectly agree with him, and think ourſelves juſtified on the ſame principle, to recommend leaſes to gentlemen inſtead of agreements from year to year, as intereſt will add vigour to improvements in one inſtance as well as the other.

As Arthur Young, eſq. has been a labourer in the field of agricultural improvements the greateſt part of his life, we cannot quit this part of the ſubject without taking ſome notice of ſuch of his works which we have had the pleaſure to ſee. When Mr. Young firſt ſtarted as a public man, whether profit or amuſement were his purſuits, we know not, or whether he entered himſelf for the public good; the high flattering manner in which he ſpeaks of the various noblemen and gentlemen he viſited, his inflated and poetic deſcription of their manſions and agriculture, and, above all, his conſtant advice to them to raiſe their rents, in order to make their tenants induſtrious and thrifty. Theſe are maxims which ſeem to indicate that Mr. Young wanted to curry favour with thoſe who were able to beſtow it; for we cannot believe oppreſſion can be exerciſed with ſucceſs, to ſtimulate induſtry. Indeed the fruitful manner in which Mr. Young delivers himſelf at the concluſion of the firſt volume of his annals, and in other places, are plain proofs that he is a diſappointed man. We hope experience and extenſive travelling have given him a better opinion of Engliſh huſbandmen than he entertained when firſt they were honoured with his viſits, and that he is convinced of the wide difference between ſpeculative theory and rational profitable practice. The variety of academic honours this author is enabled to annex to his name may be food for ambition, and add conſequence to a title page, but liberality of ſentiment, and a juſt record of events, are certainly of more value to the community. That the annals are in many inſtances a candid ſtatement of facts, elucidated with fair and liberal digreſſion, by Mr. Young the editor, we acknowledge with pleaſure, and admire the open manner in which he frequently delivers his ſentiments on agricultural improvements. We hope, likewiſe, Mr. Young has experienced the ſweets of his preſent publication, and could wiſh him to have ſome mercy on the purſes of his ſubſcribers, and only admit ſuch correſpondence as conveys ſome new idea, or to add to ſuch ſubjects as have been before ſlightly touched upon. By this time we ſhould ſuppoſe him ſufficiently experienced in theory and practice to be competent to the taſk of ſelecting the uſeful from the uſeleſs; as inconſiſtencies, and tedious repetition, are poor amuſement, and convey no inſtruction, however learned or high in life the author may be. Anonymous correſpondence being contrary to Mr. Young's plan, what can be his motive for ſo frequently admitting ſuch effuſions of uncertain experiments from unknown authors?

George Winter, eſq. a gentleman of independent fortune, who cultivates the land for health, amuſement, and to ſerve his unenlightened neighbours, has recently publiſhed a *compendious Syſtem of Huſbandry*, particularly recommending the drilling of grain and all kind of ſeeds. Mr. Winter has likewiſe had the good fortune to invent a new drill plough, for which he has obtained *his Majeſty's Letters Patent*. Had the inventor of the machine made the public good his ſtudy, we ſhould have given him credit for a ſhare of diſintereſted patriotiſm; but to publiſh information, and to ſell ſuch publication for nearly double the price he could have afforded it at, is not accomodating himſelf to thoſe who are in need of inſtruction. This compendious ſyſtem contains ſome ingenious and learned obſervations. But at the ſame time it has many diſtinguiſhed ſingularities in which we cannot agree with the writer, eſpecially in his treatment of pigs; in which he recommends, before they are turned out to graze, the uſe of ſpirits of hartſhorn, the uſual application to thoſe who are troubled with hyſterics. We do not wiſh to depreciate Mr. Winter's very novel improvements, but cannot help ſuggeſting, that beans, peas, or barley meal will anſwer the medical purpoſe, and are articles eaſier procured and better adapted to the conſtitution of the animal. There is very little public ſpirit in gentlemen procuring patents: ſuch monopolies are, in ſome inſtances, excuſable in mechanics; but a man who ſtiles himſelf independent in circumſtances and mind, muſt ſurely forget himſelf when he procures a patent, on purpoſe to enhance the price of a uſeful machine three times above its real value. Without an intention of giving offence to any individual, we are determined to ſpeak with the ſame freedom reſpecting our cotemporaries, as we ſhall of thoſe whoſe works are only left to anſwer for themſelves: and we are ſorry to obſerve, ſeveral gentlemen, profeſſors of agriculture, have obtained patents for inventions not their own, thereby injuring the working mechanic; and if any benefit would acrue to the public from ſuch inventions, thoſe who ſhould reap the advantage are precluded from their ſhare by the enormous price of thoſe experimental machines. This conduct may be conſiſtent with the old adage of "every man for himſelf," but there is very little fellow-feeling, or genuine philanthrophy, in the meaſure.

Thus having prefaced our ſyſtem of huſbandry in as conciſe a manner as poſſible, we ſhall proceed to the theory and practice of the art, thinking it will be moſt acceptable to our readers to blend them in the ſame ſection under the reſpective heads of

1. The various kinds of ſoils and obſervations.
2. Manures, and to what ſoil beſt adapted.
3. Wheat, and its cultivation.
4. Barley, ditto.
5. Oats, ditto.
6. Beans and peas, ditto.
7. Vetches, rye, buckwheat, and lentils or tills, ditto.
8. Clover, rye graſs, and trefoil, ditto.
9. Saintfoin and lucerne, ditto.
10. Other graſſes not generally in uſe, ditto.
11. Cabbage, turnip cabbage, and rape, ditto.
12. Turnips, ditto.
13. Potatoes, ditto.
14. Carrots, ditto.
15. Mangel Wuzzel, and other roots generally in uſe, ditto.
16. Hops, ditto.
17. Flax and hemp, ditto.
18. Madder, woad, &c.
19. Meadow and paſture overflowing, draining, and cleanſing, ditto.
20. Hay, its management.
21. Dividing and incloſing, with the management of fences.
22. Horſes and oxen, as uſed for huſbandry.
23. Cows and dairy.
24. Sheep.
25. Pigs.
26. Apples, pears, and the making of cyder.
27. Such timber and other trees as are connected with agriculture.
28. Implements in huſbandry.
29. Ploughing, harrowing, and cleaning land.
30. Sowing, drilling, and other means of depoſiting ſeed in the earth.

I. *The various kinds of Soil.*

Soils are generally diſtinguiſhed by loam, clay, ſand, and chalk, each of which has its reſpective kinds. As we do not purpoſe to enter into a chemical analyſis of their nature and quality, we mean to give a ſimple and plain deſcription of them, ſo far as we think conducive to vegetation. Whether phlogiſticated or dephlogiſticated air is the food of plants, it is not for the practical farmer to conſider, nor has every thing that art and ſophiſtry could invent and ſay on the ſubject had the leaſt tendency to the improvement of agriculture, but has frequently diſguſted and tired the reader, and driven him from a purſuit which he had previouſly followed with pleaſure.

The food of plants is earth or ſoil, which to manure and cultivate ſhould be the farmer's care: ſome kinds of ſoil cannot be ploughed and pulverized too much, others the leſs they are ſtirred the better, as frequently ploughing is found by experience to produce thiſtles, and a variety of other weeds, in much larger quantities than when the plough has been more ſparingly uſed. Soil is made fine or reduced, and is much improved by a courſe of drilling occaſionally: but more of this when the ſubject is before us.

Loam, or native mould, is the ſoil beſt adapted for vegetation; this in its higheſt or moſt pure ſtate is from decayed vegetables and other periſhable ſubſtances, and when acted upon by the ſun and air is rendered fertile. All other ſoils capable of nouriſhing plants are compoſed more or leſs of this mould, and other leſs fertile ingredients, as clay, ſand, chalk ſtones and the like; and according to this mixture, the ſoil is prolific or barren. The ſoil thus blended by nature ſhould be the farmer's firſt conſideration, for on that depends what is called the goodneſs of the land, or the eſſential matter to the growth of crops of corn, and other vegetables. This pure mould being the lighteſt of thoſe ſeveral ſubſtances which compoſe the earth, naturally lies on the ſurface or above the others, in various thickneſſes according to the nature of the ſoil; which mixed with the under layer, bed, or as ſome term it the pan (by too deep ploughing) generally injures the fertility of the lands. The loamy ſoil in the greateſt eſtimation is known by its tender ſoftneſs and blackiſh colour, being with eaſe crumbled to pieces; it is juſtly called the heart of the land, or principal nouriſhment to herbage.

When the greateſt part of the ſoil is compoſed of this rich or vegetable mould, it is likewiſe termed loam, or loamy earth, whether the admixture be clay, ſand, or other earthy ſubſtances; for this reaſon, loamy ſoils differ in colour and quality. When a reddiſh ſand makes a part with or without a ſmall portion of clay, it is called a yellow loam; and is land well adapted for all kinds of corn, roots, and moſt kinds of graſſes: it is eaſily worked, not ſo liable to touch graſs and other kinds of running weeds, therefore eaſily kept clean. There is likewiſe another kind of ſoil generally called a tough, ſour black loam. This is compoſed of a black or blue clay, and native or vegetable mould, and is fertile in proportion to the quantity of the latter. If this ſoil is without ſmall ſtones or gravel, it requires much ploughing, and occaſionally to be expoſed to winter's froſt and ſummer's ſun; for however ſpeculative theoriſts, and thoſe determined friends to the drilling ſyſtem, who figure away in Mr. Young's annals, may argue and attempt to prove to the contrary, we will venture to pronounce that no perſon can manage this kind of land, and a ſtiff clay, to a proper advantage, unleſs he ſometimes turns it up to the froſt and ſun; but this comes more properly under *the article following*. This ſoil is ſubject to a variety of weeds, as couch graſs, docks and others equally difficult to deſtroy, which renders frequent ploughing, and careful weeding the more neceſſary; wheat, oats and beans are the grain beſt ſuited to this kind of ſoil, and turnips, if cattle can eat them off in the winter, without injuring themſelves or the land by treading it;

or turnips may be drawn and carted off the land for cattle in houſes or on paſture. This method renders the crop of turnips very uſeful, but does not enrich the ground on which they grew. Clover and rye graſs, with a ſmall mixture of trefoil, are the beſt graſſes to ſow on a ſtrong loam; if it is continued graſs no more than one year, clover alone is preferable.

A loamy ſoil with a mixture of ſmall round ſtones is, beyond a doubt, the moſt pleaſant land a man can cultivate, and although not poſſeſſed of ſtrength equal to the land we have been juſt taking notice of, is, for general culture, ſuperior. All kinds of grain, graſſes of all ſorts, turnips, and potatoes, may be cultivated with advantage, and if the farmer does not covetouſly crop it too much, it will prove the moſt profitable land he can plough. Loam mixed with pebbles, or flints, is generally called a gravel loam; it works eaſy and may be cropped like a ſtoney loam, but requires more manure, and is not ſo certain.

Clays are of various colours, as red, blue and white, darker, or lighter, according to the ſort which is predominant: they all agree in their general nature, and may properly be treated of together. Clays are cold and tough, retain a great deal of moiſture; or, on the contrary, when completely dried, the ſurface becomes ſo very hard, that the rains do not eaſily penetrate. In proportion as clays are united with natural or vegetable earth, ſo is their fertility to be eſtimated, their colour is not to be regarded, but their quality. The ſun and froſt are friendly to all kinds of clay ſoil, and lying wet in winter is particularly injurious. The plough ſhould not be ſparingly uſed on clay in dry weather, and the rougher you lay it expoſed to the froſt or ſun the better. Cattle lying on clay in winter materially hurt the land, and it ſeldom benefits the cattle. Buck wheat, or tetches, ſowed and ploughed in, is a good and cheap improvement, which will be conſidered under the article *manures*. Wheat, rye, beans, and clover, ſeem beſt adapted to grow on clay.

There are ſeveral kinds of ſand diſtinguiſhed by their colours, as brown, red, yellow, and white; theſe ſands without a mixture of earth, or clay, are barren, being only the ſport of winds not ſufficiently adheſive to afford any nouriſhment to the roots of plants. Sand, when it thus forms the covering or ſurface of the earth, muſt be called the ſoil; but being ſo uſeleſs in its nature is ſeldom cultivated to any advantage. If clay, or marle, can be eaſily obtained it may be improved, but at too great an expence to fall upon a tenant; therefore, this kind of ſoil is not what we would wiſh the huſbandman to underſtand as a ſandy ſoil. We mean a ſoil in which ſand is predominant, although there are other kinds of earth in the mixture.

Sandy ſoil, when the ſand does not make too great a part, are cultivated with profit and eaſe, as they are worked in all ſeaſons with leſs difficulty than any other kind of land. Sandy ſoils are warm, or cold, according to the ſubſtances with which they are incorporated; thus, when mixed with pebbles, or flint, it yields its produce more early, and is ſubject, if paſture, to be burned up by a continuance of dry weather; and if arable, is rendered almoſt barren by what is called a dry ſummer. This is enriched by turnips, if cattle eat them off in a proper manner; crops of ruſk wheat, or other juicy vegetables, ploughed in before they bloſſom, alſo add much to its fertility, perhaps more ſo than on any other kind of ſoil. Wheat, barley, peas, and all kinds of graſſes, are adapted to the gravelly ſand; and ſtrong manures will always meet a welcome reception, and quickly loſe their virtue.

A ſandy ſoil with a mixture of red mortary earth, which runs to a conſiderable depth, is generally backward in yielding its produce, and not ſubject to burn, or feel the effects of a continuance of dry weather; this, although light in its nature, is ſuperior to the former, and is particularly adapted to oats, rye, and peas, as it ſeldom produces wheat, or barley, of a good colour, or quality. Turnips, potatoes, and particularly carrots, grow to great advantage on this kind of ſandy land: rye, graſs, trefoil, and clover, generally give good crops, and it is likewiſe well ſuited to natural graſs. On this ſoil the drill, or, what the ſpeculiſts call the new huſbandry, will be found a great improvement, as no more ploughing than juſt to keep it clean is the beſt management.

Without a mixture of other kinds of earth ſand is almoſt barren; but with a due proportion of other earthy ſubſtances it is fertile, requiring little labour and that performed with eaſe, except tough clay forms a part, in which caſe there is no ſoil more binding.

Chalk is of different kinds, ſome being hard as a ſtone, and others ſoft like marle: this renders a different mode of management neceſſary. One kind of chalky ſoil will be little benefited by what would improve the other. It is generally eſteemed the harder the chalk which makes part of the ſoil, of leſs value the land; and the ſofter the chalk, of greater value. It is much in favour of chalky ſoils, that they are the leaſt of any over-run with weeds, except ſome few of the annual kind which are eaſily kept under with little difficulty. The light, looſe, chalky ſoil, requires little ploughing, and too much is ſure to be an injury, by rendering it too fine and light to ſupport and nouriſh the roots of plants.

Folding of ſheep on this kind of ſoil is particularly ſerviceable, as, beſides the benefits which accrue from the manure, the treading of the ſheep gives it a firmneſs, which, by nature, it is much in need of; ſo ſaintfoin and rye graſs are uſeful. The ſoft kind of chalk requires more ploughing, and is naturally more fertile. Wheat, barley, and peas, are generally produced in good quantities, and of the beſt quality on the ſoft as marly chalk. It ſometimes happens unfortunate, when heavy rains immediately ſucceed the ſeeding, as by that means the ſurface is ſo firmly united that the plants cannot make their paſſage through the ſoil, conſequently the ſeed and labour are loſt: this may in ſome degree be prevented, at leaſt guarded againſt, by not harrowing too fine.

As we have ſhortly treated on the kinds of ſoil, which are in general cultivation in this country; if it ſhould be alledged, that there are ſome ſorts which we have not particularly noticed, we acknowledge there are; and at the ſame time are perſuaded, that if thoſe we have omitted are not exactly the ſame, yet they bear ſuch a ſimilarity in their nature, as their culture and produce will be nearly the ſame, and under the articles manures, or ploughing, &c. will be mentioned. To give or propoſe directions to any perſon for their choice in land, would be arrogantly aſſuming a province to which we by no means think ourſelves intitled, as we hope every farmer, before he changes his ſituation will be particular in eſtimating the goodneſs of the land, with the price per acre; what ſituation it has been in, in what manner managed, and the probable improvements that can be made, with the expences that will attend ſuch improvements, and particularly to conſider the term of his leaſe, that he may have it in his power to reap the profits of his induſtry. Mr. Wiſhaw, Mr. Black, and ſeveral other perſons who are employed by gentlemen of landed property, to put a value on their eſtates, have ſcientifically obtained the appellation of land taſters, by eſtimating the degrees of fertility which belonged to the ſoil and its quality, according to their palate. On what criterion theſe gentlemen found their ſkill, we cannot determine; but we can inform them and the public, that many induſtrious huſbandmen think their mouths muſt have been out of taſte, at the time the farms they rented were under their inſpection; for induſtry can ſeldom meet its reward, where thoſe ſpeculative appraiſers have made their appearance.

Strange as this may ſeem, it is really true, that it is at this time a prevailing cuſtom for gentlemen, when they think proper to raiſe their rents, to apply to an eminent *Land Taſter*, who perhaps reſides an hundred miles or upwards from the place where he is employed, and never ſaw the lands before, and whoſe reputation is in proportion to the oppreſſion he has been the cauſe of. When this important regulator arrives, his firſt buſineſs is to examine the *rent roll*, and make ſuch minutes as are neceſſary, to prevent his running into error: thus equipped he takes the field, and ſacrifices the ſucceſs and happineſs of thoſe individuals and their families, who are ſo unfortunate as to have their farms ſubſtituted to the teſt of this pretender's *taſte* and judgment.

It may be ſaid, if the tenant does not approve of the alteration, it is at his option to provide for himſelf in another place; he may ſo, but let it be recollected that thoſe advances are generally made at the time when a tenant has made expenſive improvements; which, with the difficulty and expence of removing, and the uncertainty attending agricultural concerns, frequently induce a man to endure an evil he knows ſomething of, than to hazard his property, where he is a ſtranger; beſides, *land taſters*, ſurveyors, and mercileſs landlords, are become ſo numerous, and taxation ſo high, that a tolerable farm is rare to be met with.

In oppoſition to thoſe gentlemen, and as friends to humanity and induſtry, we with reſpect mention the names of Mr. WILLIAM MARCO, Barrow, R. LEGRAND, Eſq. of Guilton houſe, WILLIAM HALL, Eſq. of Elmſtone, and ſome few others who correſpond with Mr. Young in his Annals. The writings of theſe gentlemen are evident proofs that they are friends to their country, to induſtry and agriculture; not judging as theoriſts, but as ingenious and liberal practitioners, who highly deſerve the farmer's moſt cordial thanks for their communications. As a contraſt to theſe characters, we cannot omit the reverend Mr. Fiſke, of Shimpling, near Bury, Suffolk. The following appears in one of his letters to Mr. Young, publiſhed in the 5th volume of his Annals, "Small farmers are obliged always to have ſome crop on their land, or they could not live, therefore, ſubſtitute clover, beans, peas, or ſomething inſtead of fallowing. Here is a ſtriking inſtance, that large rents encourage induſtry, and I believe nine times in ten advance in rent will be found of ſervice. For no ſooner is a farm raiſed but the farmer rouſes from his lethargy, opens his eyes, and contrives ſome method to pay the additional ſum." True, Reverend Sir! Otherwiſe he muſt go to gaol, and his family into the work-houſe, except, indeed, he turns his own executioner, and puts an end to a miſerable life; or another expedient, he might "contrive a method" to rob his neighbours; and then the law would find an executioner, and alſo a parſon to take care of his ſoul. Suppoſe we aſk the Reverend Mr. Fiſke, if a poor unfortunate curate who with the utmoſt ifficulty procures a neceſſary ſuſtenance for himſelf and family, s not a greater object of compaſſion than the fat and haughty ector who rolls in plenty, takes his tythes in kind, and tyrannizes n a truly Nabob ſtyle as far as his authority extends? If this is nſwered in the affirmative, ſuppoſe we transfer the analogy to poor hard working tenant, who labours hard, and fares badly; nd his wealthy landlord, who knows no want, but that of a ood appetite, and who, inſtead of feeling the excruciating pains ttendant on a poor *half-ſtarved rheumatiſm*, enjoys himſelf with *fine luxurious gout*.

The caſe being thus briefly drawn, do, Mr. **Fiske**, tell us in what manner this rich man, who lives in plenty and idleneſs, can beſt ſerve the poor man who owes his exiſtence to hard labour and active induſtry? Would it be charitable, or juſt, in either caſe, to rob the indigent man, and give to him that is opulent? This ſeems to be your opinion.

As you have already anſwered the queſtion, by aſſerting, that the way to make the farmer thrive, is to raiſe his rent. This, we think, needs no comment, as it ſufficiently ſpeaks for itſelf; we, therefore, take our leave of you for the preſent, in a few words. If thoſe, reverend ſir, are your ideas, as a man and citizen of the world, we deſpiſe your deſpotic notions, and feel for your dependents. If, as a chriſtian and a divine, we are apprehenſive you do not inculcate or practice thoſe fine morals which your religion teaches.

Being led from the obſervations which commenced this ſection, by accidentally meeting with the truly charitable opinion of this reverend gentleman, we return to the ſubject; and, although our opinion is in oppoſition to the whole *land taſting* fraternity, yet we take the liberty to recommend to the gentleman or farmer's notice, the general appearance of herbage and vegetation, in preference to the taſte or colour of the ſoil.

If winter happens to be the ſeaſon, the ſtrength and appearance of ſtubbles, with the dry or wet ſituation land appears in, and whether the land will endure treading by cattle or not: and if paſture, whether graſs appears thick or thin, if over grown with a ſtrong courſe of moſs; or if its general appearance is green, or of a whitiſh caſt; likewiſe what improvement can be made by draining, cleaning, and other operations?

In ſummer, if the ſeaſon has been regular and kind, the appearance of land ſpeaks for itſelf, nature has then clothed it in its beſt garment; whether good, bad, or indifferent, is the queſtion which the enquirer ſhould make himſelf acquainted with. Meadow and paſture are ſometimes very deceiving, when in the moſt luxuriant ſtate, as frequently the white bloſſomed clover and other delicate plants appear, in the greateſt plenty, on account of a friendly ſeaſon to this ſweet herbage, when on other ſeaſons nothing of the kind ſhews itſelf. Theſe circumſtances require a perſon ſhould conſult ſome one acquainted with the land. The beſt arable land may, indeed it does very often, bear an unkind aſpect from bad management, which a perſon with a ſlight knowledge of buſineſs will eaſily diſtinguiſh. For inſtance, if the growth of grain carries with it the appearance of poverty; the nature and ſituation of the weeds are evidences ſufficient with a diſcerning practical farmer; and as every country has ſuch uſeful men, we recommend the young and unſkilful to adviſe with ſome *ſage experienced neighbour*. It is a cuſtom with ſome perſons to take the growth of timber and other trees, and the favourable appearance of hedges, as a never failing rule to judge of the quality of the land; but this we can from experience refute; as very often trees and fences grow in the moſt luxuriant manner, and corn and graſs very indifferently; and on the contrary, good corn land frequently bears wood very badly. Beſides, one half of the hedges are ſpoiled by bad planting; or, perhaps, worſe management; of courſe, little information can be expected from ſuch a theory. By this we mean to guard the huſbandman againſt a too haſty determination; for deliberation on cauſes and effects, in general, amply pays thoſe who apply with careful caution.

SECT. II.

MANURES,

AND TO WHAT SOIL EACH IS BEST ADAPTED.

As we have conſidered the nature and cultivation of ſoils, and made ſome obſervations on their uſes; manures, the great ſupport and ſtamina of continued cultivation, come next before us. Pulverizing the land with the plough, and other implements adapted for the purpoſe, and the enriching it by natural and artificial compoſts and manures, are circumſtances on which good huſbandry chiefly depends.

We purpoſe treating of manures under the diſtinct heads, Animal, Artificial, and Natural Manures. To ſpeak of the dung of animals, as chymiſts, we do not conceive neceſſary: Why ſhould a farm yard be converted to a labaratory?

We cannot help taking notice of the **Encyclopædia**, publiſhed in Scotland; ſeveral numbers are taken up with a Syſtem of Agriculture. We ſhould have been happy to have improved our reading and experience, by conſulting that voluminous work occaſionally; but, on peruſal, we find a ſelection from Dr. Prieſtley's Philoſophical Labours, the Practice and Theory of Lord Kames and Mr. Anderſon, and a few of the Bath ſocieties papers, make a great part of their ſyſtem. However learned the editors of that great undertaking; in agriculture they are notoriouſly deficient; ſome few glaring errors we ſhall mention in the courſe of our ſyſtem; for ſhould any perſon be weak enough to follow their directions, in ſome matters, they would be inevitably miſled.

ANIMAL MANURE IN GENERAL.

As vegetation naturally exhauſts the land, ſo cattle which depaſture, by leaving the dung and urine, ſupply the defect, by returning from whence it came, what they had previouſly taken from the ſoil. If land is mowed and loſes its produce every year, and never receives any aſſiſtance from manures of any kind; ſuch land is greatly injured, and in proceſs of time the beſt ſoil may be reduced low and impoveriſhed. Animal manures ſtand foremoſt, and thoſe animals which feed the higheſt produce manure of the greateſt value; in fact, the virtue of animal manures may be eſtimated by the food which is given to the animal. Cattle of the cow kind, kept in a ſtraw yard, without any thing but ſtraw for their ſuſtenance, yield a poor light manure, little ſuperior to natural ſoil; when cows or oxen feeding on good hay, aſſiſted by corn, oil cake, or other envigorating food, yield a manure little inferior to the beſt horſe dung. Thus, the ſtronger manures are impregnated with animal ſalts, of more value they are; to preſerve ſuch ſalts requires the utmoſt care; and of all careleſs neglects in farmers this is the greateſt, it being deemed an object worth notice with but few.

Every huſbandman will tell you that one load of ſtable dung is worth five from the ſtraw yard, and yet, at the ſame time, permits his yards and dunghills to drain themſelves of their virtue, unnoticed and diſregarded. We will not comment on this miſmanagement, any further than by obſerving, that many gentlemen and experimental farmers have taken this matter into conſideration and practice, much to their credit and judicious diſcernment; while farmers who pay heavy rents, and ſhould let no opportunity of enriching their land eſcape, ſuffer the moſt eſſential part of their manure to paſs away as uſeleſs, and to anſwer no good purpoſe whatever. It is a cuſtom to turn dung and expoſe it to the air and weather in the yard; this is certainly founded in error; by ſuch means all fermentation is ſtopped, and its ſtrength is evaporated by wind and ſun; therefore let it be avoided. Should a leiſure time preſent itſelf, it is by all means to be recommended to the farmer to take the dung from his yard in its crude and undigeſted ſtate, near to the place he intends to uſe it, and mix it with earth taken from waſte roads, or if that is not in his power, from a headland or other part of the field which preſents itſelf.

It ſhould be obſerved, that in general the ſoil throwed up, and carted off with the manure, is amply reinſtated by the natural and unavoidable drainings from the compoſt heap. More on the preſervation of the virtues of manure we ſhall obſerve as we proceed.

The dung of animals, as we have obſerved before, poſſeſſes a fertilizing quality in proportion to the quantity of animal ſalts it contains: we ſhall rank them according to their quality, and the quantity of each, which can be procured to make it generally uſeful; as we deem it uſeleſs and unneceſſary to deſcribe every minutiæ of an article, which, from the nature of things, it is impoſſible to procure a ſufficient quantity to be of general uſe.

OF HORSE DUNG.

The Dung of Horſes, we mean thoſe which are kept in ſtables, is firſt in general utility, and improves all kinds of ſoil. Sir Hugh Platt ſays, that from experience he knows that "one load of grain or fruit well conſumed, and laid on a ſpot of ground, will enrich it more than ten load of common horſe dung." To give implicit credit to this circumſtance is more than we can readily aſſent to, although Sir Hugh's authority is very great; yet this may remove the doubts (if there are any) of thoſe who do not ſufficiently eſteem the dung from animals highly fed. Horſe dung ſhould be well fermented and decayed before it is laid upon the land; otherwiſe mixed in a freſh ſtate, with earth, which ſhould lie together until they are incorporated. This valuable manure laid on land too green or new, beyond a doubt encourages weeds, which we attribute to its ſuperior ſtrength or ſpirit; as what makes weeds grow luxuriant and ſtrong, will alſo make more valuable plants flouriſh with greater vigour.

As a Horſe chews his food but once, oats are ſeen frequently to paſs through them undigeſted; this often prevents thoſe who are curious in preſerving their corn for ſeed, from manuring their land intended for barley or wheat with the produce of the ſtadle: this obſtacle is entirely removed by letting it become rotten before it is uſed.

The dung of Horſes and all others of a warm kind, particularly benefit poor barren land; and on theſe we need give no caution reſpecting quantity, as people generally diſtribute their manure according to the land which wants it. It is certainly much the beſt way to manure land well when it is attempted, provided you do the leſs quantity.

Of good Horſe Dung, twenty cart loads upon an acre is thought a tolerable good dreſſing, each cart load a ſmart draft for three ſtrong horſes on level ground, perhaps thirty hundred weight.

On rich loamy land you may run into an error by too much kindneſs in manuring; ſhould that happen, we know of no better remedy in ſuch caſe, than a crop of flax or hemp, which will ſoon reduce it to the ſtandard for corn.

Every horſe dunghill is not of the ſame richneſs, although the horſes may feed the ſame; for there is much to be ſaid reſpecting the quantity of litter that has been uſed.

COW DUNG.

By Cow Dung is meant that of all horned or neat cattle. In treating on Horſe Dung, we have attempted to explain the occaſion of heat and cold in the effects of dung in general. As the higheſt fed cattle produce the ſtrongeſt manure from the goodneſs of their food, it follows by the ſame rule, that cow dung ſhould be cold and ſpiritleſs in proportion to the virtue of its feed.

Cow dung, eſpecially when the animal has good hay given, is an excellent manure, although not ſo ſtimulative as horſe dung; its nature is particularly adapted to promote vegetation. This animal manure deſerves more eſtimation than it really has; particularly that made in yards, and not lying in a ſituation to receive too much rain, nor to drain itſelf dry from urine and other moiſture.

The dung of horned cattle does not ferment ſo ſpeedily as that of horſes or pigs, provided the animal feeds equally high; perhaps this may be accounted for by the additional fermentation it receives in the ſtomach, by chewing its food a ſecond time.

On cold ſtiff clays, or loams approaching to the ſame nature, cow dung does not ſhew itſelf with equal advantage to thoſe of a warmer kind; but on warm gravel, or ſand, provided it has been carefully preſerved, it will not be found materially inferior.

The utmoſt care is neceſſary to keep this manure from being expoſed to the ſun and wind, and (indeed as you ſhould with all others) plough it in immediately as it is laid on the land; mixing it as ſoon as poſſible with earth, is good management.

HOGS DUNG.

Some of the old writers on Huſbandry diſcarded the manure made from pigs, which erroneous prejudice has been followed by ſome of a later date; but we will take the liberty to obſerve, that ſuch perſons could only write to increaſe the number of books.

The principal faults they diſcovered in the dung of hogs, was, that it "was poiſon to land, and produced nothing but weeds." Curious as this may appear, it is really a fact, that ſo fooliſh and abſurd a notion is not yet entirely exploded.

To any perſon of experience and obſervation, ſuch cenſure as this muſt be diſregarded; for it is rational, that what forwards the growth of one plant, will promote that of another.

The dung of pigs, particularly thoſe that are feeding, is unqueſtionably of the firſt quality, and laid on ploughed land in too large quantities, freſh from the PIGS COT, will cauſe weeds to grow; but reaſon ſhould direct every perſon in all their purſuits; and an error committed, is generally an ample leſſon to a circumſpect man.

It is rather foreign to our plan, to lay experiments before our readers, as we derive our information from a truly practical ſource, which we are of opinion, may be depended upon: but as an inſtance lately preſented itſelf much in favour of the manure now under our conſideration, we will preſent it to the public.

Mr. JOHN DAVIS, an ingenious practical farmer of LITTLE ROLLRIGHT, in the county of OXFORD, being led by curioſity to try the effects of pig dung, unmixed with any other, on a light ſtony loam mixed with ſand, manured about an acre with four cart loads of pig dung, not in a rotten and decayed ſtate. The acre on which this manure was laid, run acroſs the middle of a piece of about twenty acres which was under preparation for turnips, according to the uſuage of the country; or, more properly ſpeaking, a ſpring fallow, which generally happens in theſe hilly countries on oat ſtubble, after the land has been exhauſted by three preceding crops.

The lands on each ſide that we are mentioning, which was manured with pig dung, were dreſſed with about twelve or fourteen loads of good horſe dung to an acre, and all received the ſame plowing, harrowing, and other management. The reſult was, the acre on which the pig dung was laid, looked in a more kind and promiſing manner as ſoon as the turnips appeared; they were leſs annoyed by the fly or ſlug; and when at their full growth it was imagined produced double the quantity to any other part of the field of the ſame meaſurement.

The ſucceeding crop of barley bore a manifeſt ſuperiority on the pig dung manure; and the rye graſs and clover, ſowed among the barley, in order to lay the land down for two years, appears at this time more luxuriant, and of a darker colour than the lands manured with horſe dung on each ſide.

This circumſtance is evidently in favour of the dung made from pigs, as ſuch we think it worthy of notice; but it ſhould be conſidered, that it is the cuſtom in thoſe parts of OXFORDSHIRE, GLOCESTERSHIRE, and the adjacent country, not to litter their feeding pigs; of courſe the dung is entire, and free from any mixture of ſtraw or other ſubſtance. Neither do we ſuppoſe any fermentation has ever taken place, which renders the ferment more powerful with the ſoil: horſe dung uſed in the ſame manner, would in all probability be equal in virtue; the experiment might be eaſily proved.

Pigs in their nature are a very cleanly animal; this may, perhaps, be objected to by thoſe who are unacquainted with them particularly; although nature has not endowed them with thoſe ſenſitive organs of ſmelling and taſting, correſpondent with human delicacy, there is not an animal that will keep the place he ſleeps in, ſo clean as a pig will; provided the ſtye or cot is conſtructed in a proper manner.

The place of reſt or retirement ſhould be covered in, with the bottom paved with ſtone or ſome other materials, and a court adjoining walled in to give them their food.

It is uſeleſs to litter the place where they lie, as they enjoy themſelves in a cooler manner on the pavement; and there is not one pig in twenty but what will go into the court where he eats his food, and evacuate. If this court is littered or ſtrewed with ſtraw, or for want of ſtraw, earth or ſand to abſorb the urine, and keep the dung from drying, and frequently cleaned out, a great deal of valuable manure will be procured, and by that means preſerved.

Trivial as this obſervation may ſeem, it will be of more real advantage in practice, than will at firſt be imagined.

Pig dung on meadow or paſture is of great utility, mixed with ſoil it is uſed to the beſt advantage; and the moſt proper ſeaſon to lay it on is when the graſs begins to grow in the ſpring.

SHEEP DUNG

Is by experimentaliſts held in great eſtimation as a forcing ſtrong manure; certain it is that the folding of ſheep is much practiſed, and the ſucceſs attending it very great. But we do not believe it equal in virtue to either horſe or pig dung; as Mr. Davis who made an experiment with the manure from pigs, made alſo the like from ſheep, in a much larger quantity per acre, which by no means anſwered his expectation.

Folding, or penning upon land, is ſufficiently known to need any particular deſcription, and when a large flock are managed carefully, and the fold not hurried too faſt over the land, a good purpoſe is anſwered.

Land ſhould be ploughed as ſoon as poſſible after folding, otherwiſe no benefit is to be expected, except from the urine, which it is reaſonable to ſuppoſe, is in ſmall quantities, as ſheep ſeldom drink, ſometimes not when they live on dry food.

Sheep are often folded on light hollow ſandy lands, and dry hard chalk, after the ſeed is ſown, particularly wheat; this is intended to tread the land, and to improve it by making it more firm, as well as to add ſome benefit by manure: care ſhould be taken, and caution uſed in wet weather, alſo when the corn appears.

We have known ſheep drove morning and evening over turnips, when the fly or ſlug has been ſuppoſed to be buſy; and doubtleſs to a very good purpoſe, although ſuch exerciſe is by no means ſerviceable to the ſheep, particularly thoſe which bear heavy fleeces.

To houſe ſheep on nights, and litter them with ſtraw or haulm, or for want of thoſe, with ſand or fine gravelly loam, has furniſhed topics for many writers; the PLATTS, and more particularly the celebrated CAPTAIN BLYTHE, recommended the cuſtom very ſtrongly, and with as many pertinent remarks, and as much to the purpoſe as any writer of the preſent day.

This method on ſome kinds of ſoil would prove an admirable acquiſition; as a large quantity of excellent manure might by that means be obtained; to be uſed at pleaſure, and on ſtiff cold land, both that and the ſheep would be benefited; for treading ſuch ſoil does injury to both the ſheep and the land. Covered houſes, open on both ſides are preferable, with a court encloſed round according to the ſize of the flock.

On large paſture fields or downs, which are ſummer eat every year, (if ſheep are not driven to fold on ploughed or arable land) the upper part of ſuch fields will be rendered very rich and fertile by cattle, (ſheep in particular) lying on thoſe higher parts.

As the folding of ſheep on poor moſſy paſture is very improving, it would amply repay the trouble and expence to drive ſtore ſheep to fold to an adjoining paſture, which is occaſionally mowed for hay; it would be the means of helping land which wanted, without injuring that which was ſufficiently rich.

According to the preſent management of ſheep, their dung is not an important article in agriculture, any further than as they diſtribute it themſelves.

There is not a doubt that care and attention, by houſing them on nights as before deſcribed, with racks to give them hay or other food, as may be thought proper, would be a great advantage, and when put in practice attended with very little trouble.

Eating turnips off the land with ſheep, in a proper manner where the ſoil ſuits, is one of the greateſt points in the turnip culture; we ſhall be more particular under the head turnips.

The obſtacle to new methods are very formidable, in imagination, but deliberate perſeverance makes ſmall difficulties light and eaſy.

Having deſcanted on the uſe and properties of manure raiſed from thoſe domeſtic animals, which are conſidered neceſſary to the purpoſe of huſbandry in our own country, we ſhall proceed to poultry or fowl.

DUNG OF POULTRY.

By poultry we mean hens, ducks, geeſe, pigeons, and whatever elſe our readers think proper to rank with them, as no injury can accrue from uſing them as manures indiſcriminately.

Theſe contain large quantities of the eſſentials, which conſtitute ſtrong manures; and we believe principally to be attributed to fowl not having any evacuation by urine, and their feeding chiefly on corn.

In inland countries, where rich manures are not to be purchaſed, it is an object worthy the farmers notice to carefully preſerve every thing, be the quantity ſmall or large, which can add to the fertility of the land.

Prepoſſeſſed highly in favour of this method, we are certain a valuable ſource for manure lies neglected by the multitude with reſpect to the dung of fowls.

To litter with ſtraw, or lay ſand or dry mould where poultry lie, and clean them out often, and again repleniſh the litter, would produce more manure, and that of the beſt qualities, than any one not maturely conſidering the ſubject would imagine.

We would recommend this manure to be uſed on meadow, paſture, or arable lands, particularly on thoſe of a cold nature, and are well aſſured, all trouble and expence would be fully paid.

It is a cuſtom to uſe pigeons dung, by ſowing it upon young wheat for the rain to waſh it in; ſome advantage may attend ſuch a practice; but ploughing it in on arable land, is by far the moſt preferable method.

HUMAN ORDURE.

This ſhall be called, if you pleaſe, animal manure; but reſpect to our ſpecies prevented our connecting it with brute, although the word brute is frequently diſgraced by the compariſon.

An eminent writer on Agriculture, ſays, “ There is ſomething “ diſguſtful in the thought of uſing the excrement of our ſpecies, “ for the dreſſing of lands, as it is putting it again down our “ mouth.” This gentleman was certainly of a very delicate turn, as the celebrated **DEAN SWIFT** obſerves, “ Nice people have the moſt naſty ideas;” and a more filthy thought than this ſurely never entered the moſt delicate brain, even if we conſider that of a fine lady.

Do not let your nice feelings be alarmed, fair reader! For we are under the neceſſity of informing you, that the greateſt part of the vegetables and roots uſed near the metropolis and other large places, owe their forwardneſs and luxuriant appearance to the fertilizing manure now under our conſideration.

Of all others this makes the moſt exciting compoſt, and ſhould not be uſed until it has lain well mixed with earth, ſand, or clay, a conſiderable time; the mixture to ſuit the huſbandman's convenience, or the kind of ſoil he intends to uſe it upon.

Doctor Prieſtley, Mr. Young, Mr. Winter, and all the tribe of chymical and experimental farmers may diſpute, and try to diſcover the food of plants; but we defy any of them to find a more nutritive and ſubſtantial food for all kinds of plants, than this we are now ſpeaking of; if properly adminiſtered.

This manure, as previouſly obſerved, cannot be obtained, except near large cities or towns; therefore, we adviſe thoſe who have an opportunity of getting it, by no means to let it paſs unnoticed; obſerving to mix it well with earth, and let it lie thick near twelve months.

ARTIFICIAL MANURES.

This brings us to artificial manures: we deem thoſe artificial which are calcined or undergo ſome proceſs before they are rendered of uſe as manure, and which we diſtinguiſh by **LIME**, **SOOT**, **ASHES**, **RAGS**, and improving land by **PARING** and **BURNING**, commonly called breaſt plowing and burning.

LIME.

Uſing lime as a manure has been practiſed upwards of two hundred years in this country, and continues in uſe to the preſent time, which is certainly much in favour of its utility, and proof poſitive that it is advantageous. In ſome countries, where materials for fire are expenſive, it is uſed on land at the expence of eight-pence per buſhel; and perhaps fetched ſeven or eight miles diſtance, which conſiderably enhances the price.

Lime being a ſtrong alkali is ſuppoſed to fertilize land, by correcting and blunting the vitriolic acids with which moſt ſoils abound; when ſuch purpoſe is anſwered by deſtroying the effects of thoſe acids, it is ſuppoſed lime loſes its fertilizing quality and becomes uſeleſs, nay, ſome pronounce it injurious. In ſupport of this, it is generally known that lime is ſeldom uſed to ſo much advantage after the firſt or ſecond dreſſing.

In lime it is well known there is nothing of a nutricious or oily property, that can poſſibly be conducive to vegetation; and that mixed with earth in a proper manner, it ſtimulates the growth of corn and moſt other kinds of plants in a very eminent degree.

On ſome kinds of land we find it of no uſe whatever, whether the ſoil be poor or rich, conſequently it requires judgment to diſcern on what ſoil it is proper to uſe it; and likewiſe the moſt proper manner to apply it, to anſwer the purpoſe.

Some account for the good effects of lime, in quite a different manner than that above-mentioned; namely, by attracting and drawing its enriching, and fertilizing qualities from the atmoſphere; this opinion has for its advocate, the *celebrated georgical* **DR. HUNTER**, and other ſcientific gentlemen.

Such an idea as this deſtroys the common practice of uſing lime, mixed with earth or dung; and likewiſe the cuſtom of ploughing it in, as ſoon as laid on the land, as burying it muſt neceſſarily prevent its atmoſpheric attractions.

When doctors diſagree, how are farmers to determine?

By Mr. Young's leave, we will preſent our readers with a letter from the *Annals of Agriculture, Vol. 4. page 47.*

ON THE ADVANTAGE OF MIXING LIME WITH DUNG.

By ROBERT ANDREWS, ESQ. of AUBERIES, near SUDBURY.

“ CART the dung out of the farm yard, ſometime in De-
“ cember, and continue to do it as made, in the following
“ months, till the heap amounts to about 120 loads, each 40
“ buſhels; if made larger, the dung does not rot ſo well; when
“ finiſhed, leave it about two months, and then add 200 buſhels
“ of lime, which is ſold at the pit at 5d per buſhel, mix the
“ whole together immediately; but it is to be obſerved, that the
“ dung muſt not be dry, if it is, it will fire by being mixed with
“ lime; let it lie three months, and then ſtir it over again; the
“ expence of the firſt ſtirring is 1d a load, and of the ſecond $\frac{1}{2}$,
“ carry it on to the pea ſtubble as ſoon as harveſt is over, and
“ plough it in for barley; if the ſeaſon does not ſuit for cart-
“ ing, take the opportunity of a froſt; this management has
“ anſwered ſo well, that upon an average of 12 years, my
“ barley crops have amounted to four quarters ſix buſhels per
“ acre. I have at different times laid ſome dung on without
“ lime being mixed, and the difference was very perceptible; ſo
“ that from many experiments, I find it neceſſary to ſpread 12
“ loads an acre, inſtead of 10, which, with the lime, is the
“ uſual quantity.

“ The benefit reſulting from the lime is to be attributed to
“ two circumſtances, firſt, it deſtroys the ſeeds of weeds, ſo that
“ I have always found the land cleaneſt where the lime mixture is
“ laid; and, ſecond, it brings the dung forwarder, by raiſing the
“ fermentation higher. The expence of the lime 10s. an acre,
“ which holds very good for four crops; and I have, in one
“ inſtance, ſeen the difference of part of a field being manured
“ with lime muck, and the other part with muck without lime,
“ four years after it was ſpread.”

This practical information from Mr. Andrews, a gentleman, according to Mr. Young, who ſtands very high in Agricultural experience, is a matter of much importance to thoſe who uſe lime as a manure, or who having it in their power, omit it for want of being informed of its effects.

As a further confirmation of its merits and demerits, likewiſe its effects on various ſoils, the methods of uſing it as manure and other matters, eſſential to be known, we take the liberty to tranſcribe another letter from the Fifth Volume of Mr. Young's Annals, page 147.

By R. LEGRAND, ESQ. of GUILTON HOUSE, near SANDWICH.

ON LIME.

“ IN the courſe of my Huſbandry, I have frequently uſed it,
“ ſometimes upon a large ſcale, and always with ſucceſs upon
“ arable land. General method, one buſhel upon a rod, covered
“ the ſoil till it is ſlacked, then ſpread abroad, and ploughed in.

"Experience juſtifies a better way, viz. hot as poſſible from the kiln; ſpread it immediately upon the ſoil; and no more in a day than can be ploughed in the ſame day.

"I have uſed it upon ſandy, loamy, and clayey ſoils; all have have been greatly improved, but moſt ſo the ſandy.

"Upon paſture land, neither expenſe nor expectation have been anſwered.

"I have applied it ſimply, and mixed with mould, making a compoſt of 40 loads per acre, allowing 5 loads of lime to 35 of mould.

"At the ſame time a portion of land in the ſame field, and contiguous thereto, has been dreſſed with the ſame ſort of mould well pulverized; reſult, the compoſt much better than the lime alone, and ſuperior to the mould alone, more in ſeeming than in fact: both the lime and compoſt gave a more early and lively verdure; but the ſuperiority was of ſhort duration.

"In the compariſon of Chalk and Lime, it is neceſſary I ſhould ſay, my experience is decidedly in favour of chalk upon arable land.

"Lime alſo greatly cleans the ſoil from weeds, and eſpecially deſtroys the wild marygold."

We cannot ſay too much on the diſintereſted and candid manner in which this gentleman acquits himſelf in his correſpondence with Mr. Young; from ſuch a ſource, every part of the community are benefited; and the Annals of Agriculture become reſpectable and inſtructive.

To this experimental information, we add the practice of Mr. Fowler, near Chipping Norton, in the county of Oxon. On paſture, the ſoil, a ſtiff clayey loam, he mixed mould, the ſhovelings of a limeſtone turnpike road, and lime freſh from the kiln; about one eighth lime. This compoſt was collected and thrown together in the winter, and ſpread on the land early in the ſpring, about 10 cart loads to an acre. The reſult was the herbage which was before benty and thin, with a mixture of rye graſs; (owing to the land not being laid down paſture more than eight years) entirely changed its nature, growing much thicker, and conſiſted of white clover and other ſweet graſſes. The cattle fed on the part manured with avidity, and while there remained a blade uncroped, would not touch that part of the ground which had not been dreſſed.

Mr. LEGRAND obſerves that lime gave a more early and promiſing verdure, but it was of ſhort duration; how Mr. Fowler's may continue, we cannot determine, as it was done but laſt year, but it has the moſt promiſing aſpect.

The ſame gentleman, a few years ſince, uſed lime on black ſour hill land, at the time it received a ſpring fallow for turnip; but was diſappointed in his expectation, both with the turnip, and the ſucceeding crop of barley. In all probability, in the laſt inſtance, the lime was not applied in a proper manner; in fact, we think it lay on the land a long time before it was ploughed in; certainly a cuſtom founded in error.

Upon the whole, it muſt be acknowledged, lime is a fertilizing uſeful article as a manure, but not of much permanence, or to be too often repeated on the ſame land; and on ſome ſoils not beneficial equal to the expenſe.

Before a farmer runs into an expenſive uſe of lime, prudence ſhould direct him to try the experiment on a ſmall ſcale, by ſelecting ſmall pieces in the midſt of fields, uſing different quantities with different mixtures, by which advantages might be anticipated, and loſs and trouble often prevented.

The uſe of lime, in Agriculture, only comes under our conſideration at this time; directions for making, and its other uſes, ſee the Article LIME.

SOOT.

Soot, another artificial manure, which is alſo produced by fire. Soot is of different kinds, being made from both wood and coal, uſed as manures: their effects are the ſame on vegetation, although long arguments have been uſed by various writers, as MORTIMER, HALE, and others, to adapt each to particular ſoils to anſwer their reſpective purpoſes.

We can, from experimental authority, aſſure thoſe who have an opportunity of uſing ſoot, that each kind anſwers the ſame purpoſe. On ſome kinds of paſture land, ſoot does not ſhew itſelf to advantage equal to others: on meadow, where drift ſand was an excellent manure, we knew ſoot uſed at the rate of forty buſhels to the acre on a ſmall part in the middle of a meadow; the reſult was not viſible, as the ſmalleſt traces of improvement never appeared. We muſt confeſs this circumſtance is quite oppoſite to the general theory reſpecting ſoot, but thought it our duty to record it, as we ſaw the experiment tried. Thoſe who manure with ſoot, are in general well ſatisfied with the advantege which ariſe; as the following extract from the Annals of Agriculture, Vol. V. p. 148. by R. LEGRAND, Eſq. is an inſtance of.

"Soot is moſt evidently an excellent manure for paſture land. Quantity 40 buſhels per acre. I generally dreſs from 7 to 10 acres annually with it; and the ſucceſs anſwers every reaſonable expectation.

"One acre of lucerne, reſerved for my horſes, receives annually a dreſſing of 40 buſhels, and I am perfectly ſatisfied with the reward it gives.

"N. B. One rod of lucerne cut juſt before flowering, will weigh upwards of one hundred weight."

This extract from ſo faithful a reporter of cauſes and effects as R. Legrand, Eſq. we look upon as a leſſon, which may guide thoſe who have not uſed ſoot as a manure.

It is frequently ſowed on young peas and other kinds of grain to deſtroy ſlugs and ſnails, and to a very good purpoſe. The time this ſhould be done is very early in the morning, or late in the evening, when thoſe inſects are out of the earth and feeding; as the eſſential part is loſt when it is uſed in the day time, by the ſun, air, or rain.

Soot is an alkali and oily compoſition, conſequently a ſtimulative and nouriſhing manure; the ſooner it is uſed after it comes from the chimney, the better it will anſwer the purpoſe; as like other manures, its virtues fly when expoſed to the air. The beſt method of uſing ſoot is by mixing it well with earth, and on paſture ſpread it early in the ſpring; if rain comes ſoon after it is laid on the land it is fortunate, as by that means its virtues are waſhed into the earth. On arable land it ſhould be buried as ſoon as diſtributed, for the ſoil to imbibe its virtues. *Malt kiln duſt*, and *malt duſt*, the one being the ſweepings of the kiln, and the other duſt or roots ſcreened from the malt. The former is greatly ſuperior in quality, as manure it is much like ſoot in its operation on land, and in general uſed the ſame. The latter is likewiſe uſed on land, but not with equal ſucceſs.

They are both excellent to put in the houſes where poultry or pigeons lie, to mix with and abſorb the moiſture of their dung, and are improveable on arable or paſture, but moſtly uſed on paſture. This brings us to aſhes and their uſe.

COAL AND WOOD ASHES.

Mr. YOUNG has very ingeniouſly made various experiments on manures, and ſeems well ſatisfied of the good effects of wood and coal aſhes, as promoters of vegetation; particularly wood aſhes, when uſed on ſoils that abound with *vitriolic acid*. This language to farmers can only puzzle and make them ſcratch their heads, and ſhould they be prompted to conſult the rector, curate, or an apothecary, it is full twenty to one, they could not be informed whether the land contained *vitriolic* acid or not. As we hope to make ourſelves underſtood by farmers, we would adviſe them when doubts ariſe to make experiments on a ſmall ſcale, and thenthey may go to work more expenſively, with courage and ſatisfaction.

Coal aſhes, on rough ſour paſture, are an excellent manure, rendering what cattle would not eat, ſweet and palateable to them; in truth, we will pronounce it unequalled in making coarſe paſture land ſweet and fine; and if you give a good dreſſing it will endure; we mean by a good dreſſing, fifty or ſixty buſhels to an acre.

We have known wood aſhes uſed to much leſs advantage on paſture, and cannot by any means think them equal in value; they are ſometimes uſed on wheat and other corn in ſpring, but are not equal to ſoot. On all kinds of arable land, aſhes ploughed in with the ſoil, are a valuable manure, the land ſhould work fine when munured with aſhes; ſuch kind of manures tend greatly to deſtroy weeds.

Before baſilla was ſo much uſed in making ſoap, wood aſhes were difficult to procure for the purpoſe of manure; but they are of late become more plenty in ſome countries.

Soapers aſhes are a powerful manure on arable or paſture land, they being a mixture of lime, wood aſhes or barilla, ſalt, and likewiſe ſtrongly impregnated with animal oil. This manure, judiciouſly uſed, ſweetens herbage, and is in every reſpect valuable. But Mr. WINTER, *Author of the Compendious Syſtem of Huſbandry*, could not be ſerious, when he recommends "one hundred and ſixty, or two hundred buſhels per acre, on paſture;" if that is his practice, we cannot wonder at his caution; that when "uſed to exceſs he has known it very hurtful, like a man drinking too much brandy."

What we call uſing it judiciouſly, is mixing it with earth or dung in compoſt about an eighth or tenth part ſoapers aſhes, and then ſpreading about twenty load of ſuch compoſt to an acre early in the ſpring, if on paſture, and if arable when you plough for ſeeding.

WOOLEN RAGS AND WOOL-CLIPPINGS.

Woolen rags and wool-clippings are a good manure for arable lands, on any kind of ſoil; the way they are uſed is by cutting them in ſmall pieces, like taylors ſhreds, ſowing them on the land before it is ploughed, about twenty buſhels to an acre, or more, as no one need fear injuring their land by laying on too much. This manure will endure a long time, and does not yield its virtue the firſt year; but will keep improving ſeveral years.

AGRICULTURE.

Dr. **Pott**, in his Hiſtory of Oxfordſhire, ſays, woolen rags were eſteemed a beneficial manure for land, in that county, at the time he wrote; and that they have been ſo according to tradition in remote ages. Woolen rags are to be purchaſed in large quantities in ſea-port towns, and other large places; and we aſſure the farmer, they are an article well worth his notice.

To artificial manures may be added leather parings, horn ſhavings, pulverized brick, old mortar, and other matters from old buildings: theſe are of conſiderable ſervice when laid on coarſe paſture, or ſour arable; and ſhould by no means be neglected; for their uſe is very great, which experience will ſhew.

As the benefits which accrue from paring and burning, more commonly called breaſt ploughing and burning, are by means of the aſhes, and the action of fire on the earth; we proceed next to

BREAST PLOUGHING AND BURNING.

This is likewiſe in ſome countries called bumbarting, and in others denſhiring, ſuppoſed to bear an alluſion to Denghbyſhire, the county where it was firſt practiced in this country. The antiquity of this practice is very great, **Hesiod**, **Virgil**, and **Columella**, make mention of it; and it is very probable, the Romans introduced it into Britain.

Matthew of Weſtminſter, ſays, it was a practice in Wales to pare the turf from the ſurface, and burn it when dry, by which means this moſt barren land was rendered fertile.

From theſe inſtances, it is doubtleſs an ancient cuſtom; and at this time, that large extent of hills called the Cotſwold Hills, in Glocesterſhire, and Wiltſhire, are kept in cultivation by means of breaſt ploughing and burning.

Some gentlemen of landed property entertain a notion, that repeated ploughing and burning weakens and injures the land; to this we can only obſerve, that in the country we have above noticed, thouſands of acres have been breaſt ploughed, and burned once in ten years, ſometimes oftener; and ſometimes not ſo often for ſixty or ſeventy years paſt, and rents have kept riſing; inſomuch that lands, which let for four or five ſhillings per acre 30 years paſt, let now from ſeven to fifteen ſhillings; and are improved in quality.

Although Mr. Young juſt rode through it, and called it an "ill-cultivated country," we can aſſure him, conſidering the natural poverty of the ſoil, this kingdom does not ſhew ſo large a track of land in better cultivation. It is true, thoſe drilling fancies are not ſo much in vogue as they are in ſome other parts of the kingdom; but ſummer fallows for wheat or barley, have given place to turnips for upwards of 30 years.

Spring plowings and manure are the preparations for the turnip crop, which is ſucceeded by barley, rye graſs, clover, and trefoil, are generally ſowed among the barley. The land being generally broke up for wheat, if a turf of any ſubſtance is formed, it is generally breaſt plowed and burned.

Farmers have commonly a piece or two of ſaintfoin, which laſts 12 or 16 years, which when broke up is invariably breaſt ploughed and burned, either for turnips or wheat; but the former is better deemed the beſt management, and with juſtice on the poor land with which the Cotſwold hills abound.

Better crops of turnips are not raiſed in England than in the barren hills of Glocesterſhire, nor are they any where more carefully hoed; hoeing has been the general practice for more than 20 years; *but more of this, when we ſpeak of turnips.*

Breaſt ploughing and burning is a laborious exerciſe, but thoſe thoſe men who are accuſtomed to work at it perform it with as much eaſe and pleaſure as any other of the different branches of huſbandry.

Many perſons have endeavoured to invent methods to perform the ploughing or paring, by means of horſes: but as yet every effort has proved ineffectual.

It is particularly requiſite, to pare the ſurface as thin as poſſible, that the aſhes may be free from the earth calcined or burnt, which it is generally imagined is of no ſervice to vegetation: it is alſo neceſſary to pare the turf thin, as it burns much the better, particularly in wet catching weather.

On land free from ſtones or gravel, it is probable, paring the turf to burn might be performed with a horſe or horſes; a method that would make the expence much eaſier; but on ſtony or gravely ſoil, we think it impracticable.

Mr. **Winlaw**, of *Margaret ſtreet*, *Cavendiſh ſquare*, has a paring plough which he made, and has ſold many of them, and of which he has received very favourable accounts; this ſeems the moſt promiſing machine we have ever ſeen of the kind; for an engraving and deſcription, we refer the reader to the article Implements of Huſbandry, &c. alſo for the common Breaſt Plough, and its deſcription.

Breaſt ploughing is generally performed early in the ſpring, and the turf ſeldom burned till well dried by the ſummer's ſun: if it happens to be burnt long before the time of ſeeding, whether turnips or wheat, it is deemed good management to ſpread the aſhes and rib, or reſt balk, the land croſsways and very thin.

Ribing or reſt balking is performed by ploughing a furrow, and leaving the intermediate ſpace unploughed, by which means the ſurface of the ploughed furrow and that unploughed, lie one upon the other, and incloſe the aſhes between them; this prevents the wind and air from exhaling the virtues of the aſhes, and when ploughed acroſs at ſeed time ſomething deeper, mixes the aſhes and ſoil duly.

This method frequently makes, what a farmer calls, rough work; for wheat, we make no doubt, ſuch rough ſituation of the ſoil is preferable. We have known breaſt ploughing and burning performed early in the ſpring and barley ſowed; but it is ſeldom the weather will permit, and the method is by no means adviſeable. Breaſt ploughing and burning rough grunſward has been uſed advantageouſly, particularly on freſh boggy land full of ruſhes, ſegs, and other plants uſual on wet ground.

Mr. **Robert Line**, a young enterprizing farmer, of Rendecombe, near Cirenceſter in Glocesterſhire, breaſt ploughed and burned a conſiderable quantity of newly drained land; and on its not becoming fine the firſt ſummer, ſerved it the ſame the next ſpring, which made a very valuable, although expenſive, improvement.

Such exertions as theſe deſerve every encouragement, and a gentleman of diſcernment will always reward a tenant who ſo earneſtly endeavours at improvement.

In burning the turf, care ſhould be taken to attend the heaps while they are on fire, and cover in the ſmoke, when it is ſeen to riſe rapid; this is done with thoſe looſe turfs which fall down on the ſides of the heap, and one perſon will be able to attend an acre: by this care the aſhes are rendered ſuperior in quality.

We preſume it will be uſeleſs to give particular deſcriptions of paring and burning, as the practice is old and general.

If in any country there ſhould be men and their families wanting, to perform ſuch labour, in a proper manner, we are well aſſured 50 might be raiſed on the Cotſwold hills in Glocesterſhire, in a few days, who would go 100 miles, or any diſtance, if they could meet with a ſummer's labour; the price of ploughing, burning and ſpreading the aſhes, is from fourteen to twenty ſhillings per acre.

NATURAL MANURES.

In treating of natural manures is, we mean ſuch as are uſed without any previous preparation, by fire or artificial proceſs, as **Marle**, **Chalk**, **Lime Stone** pulverized, **Sea Shells**, and the effects of one ſoil upon another.

It is proverbial with old farmers, "*that ſomething may be always* "*diſcovered by digging in the earth, which will enrich the ſurface.*" How unfortunate to Agriculture ſuch an idea is not more frequently put in practice: this is a maxim well known, but ſeldom attempted. To account for this remiſs conduct in huſbandmen, we need look no further than the expence attending ſuch improvements.

In the article

MARLE,

Wherever it is found, is certainly a great acquiſition, and in thoſe countries where it is not ſought after or regarded, undoubtedly there is a groſs neglect.

The criterion by which Marle is known is its fat and ſlippery appearance, when rubbed in the hand; after being wetted, it falls to pieces like dry fuller's earth, or quick lime. If a piece of Marle lies expoſed to the ſun and air, it tumbles to pieces, bearing ſomething of a hoary appearance. If the dry powder is thrown into a briſk fire, it will crack like ſalt when caſt into the fire. Another method, by which Marle is proved, is putting it into water, if it effervice or ſparkle in the water; this trial is deemed ſatisfactory. Marles are of different colours, as blue, white, red, and yellow; the colour makes little difference, provided the quality is of an enriching nature.

Sometimes Marle is diſcovered near the ſurface, but generally deep and below different ſtrata of clay, rock, or mould; and as the quantity neceſſary to render ſervice to land is conſiderable, the expence of marling is very great.

To give a proper idea of marling and claying, we are confident Arthur Young, Eſq; as a friend to improved Agriculture, joins us, in commending the practical and concluſive opinions on the ſubject given by Mr. W. Macro, in the Ninth Volume of the Annals of Agriculture, page 117.

As ſuch genuine information cannot be too much diſſeminated, we give an extract, and although rather too much at large, conſidering our plan, which is to treat of every thing, we are well convinced our readers whom it concerns will think it much too ſhort.

On the Expence and Profits of Claying and Marling, and how far it anſwers for a common Farmer to be at all the Expence himſelf.

By Mr. W. MACRO.

"I Promiſed to give you my opinion in writing, why I thought Claying and Marling did not anſwer to a common farmer, even on a 21 years leaſe, although he might in that time improve the lands, ſo as to be worth two or three ſhillings an acre more to the landlord.

" As a well wiſher to all improvements in Agriculture, I am ſorry to find, that it is now quite out of faſhion for the proprietors of lands to bear any part of the great expence that attends Claying and Marling, and which, on that account, falls cruelly heavy indeed upon the common farmer, that has a taſte and ſpirit for improvement; and who, too, after ſpending a ſum of money nearly equal to the value of the lands he improves, lies under a certainty, I may ſay, of not enjoying the benefit of them for little more than 15 years, without the ungrateful return for all his labour and induſtry, that of being obliged to pay an advanced rent for his own improvements.

" To begin with the expence: The firſt is the filling, which (including ſpreading) is 25s. a hundred, or 2d ½ a load, with an allowance, by ſome farmers, of 2s. 6d. by others of 5s. for opening the Pit; and 1s. a load for all the large ſtones they throw out at the time of filling, the farmer to find drifts and ſtakes, for letting down what they call the falls.

" The team muſt conſiſt of four ſtrong traice horſes, and two ſhaft ditto, which for ſuch ſtrong work, muſt have very high keeping; I cannot, therefore, lay their labour at leſs than 2s. a day each, and the carter at 1s. 6d. a day, which, ſuppoſing they carry one day with another, (allowing for wet weather, and hindrance by accidents, &c.) 30 loads a day, will be about 5d ¼ per load more, making in the whole 7d ¼ a load, for filling, carting, and ſpreading.

"As farmers differ in their opinion about the quantity that ſhould be laid upon an acre, ſome preferring 80 loads, and others 70, I will take the medium, aud ſay 75 loads, which at 7d ¼ a load is

	£.	s.	d.
Per Acre	2	8	5¼
Harrowing and rolling ſeveral times to pulverize and ſpread it equally on the ſurface, per acre	0	1	6
Picking the ſtones up and caſting off, where uſed for the highways	0	0	0
Loſs by the ſtones thrown out by the labourers in the pit, the farmer ſeldom making half the money of them again, about a load to 70 loads of clay . . .	0	0	0
Wear and tear of carts and harneſs, including accidents, at a farthing a load per acre	0	1	6¾
Drifts, ſtakes, &c. &c. per acre	0	0	0
Loſs of ſeed, as it ſhould always be laid upon a layer, and lie ſome months before it is ploughed in, per acre	0	1	0
	2	12	6
Intereſt of the above ſum, for two years and a half, as it will be ſo long before the farmer gets any of his money into his pocket again . . . . . -	0	6	6¾
	2	19	9¾

" The next expence the farmer has to encounter, and which muſt ever be a bar to all improvements in Agriculture in this kingdom, as the laws now ſtand, is the tithes; for no ſooner has he been at the expence of carrying a thouſand or two thouſand loads of clay, or marle, than his good rector comes and demands a larger compoſition.

" The farmer's argument, that he has been at all the expence, and has not yet got his money into his pocket again, is of no avail; for he tells him, that the tenth of all his paſt and future improvements are, by the Engliſh laws, as firmly veſted in him and his ſucceſſors, as if a tenth part of the expence had been taken from his (the rector's) own pocket; therefore, if he will not give him ten or fifteen pounds a year more for the next three years, he muſt draw his tithes.

" The farmer unwilling to have the tithe cart come and carry away a part of the improvements, ſo recently laid on, ſays, he will agree to the advance, provided it is for the remaining part of his leaſe, if they both live ſo long: No, ſays the rector, as you are going on with your improvements, at the three years end, my tithes will be worth more, and ſo on the next, and the next three years; and ſo it is, I ſuppoſe, that ſome improved farms in Norfolk (as I have been informed) have before the firſt leaſe is expired, paid nearly as much tithes as they did rent.

" Of this, I ſhall take notice again in another place, and return to the £2. 19*s.* 9*d.* ¾, which ſum, being money ſunk upon another perſon's eſtate, the intereſt of it is not only an additional rent to the farmer, of about three ſhillings an acre, but he is in all fairneſs in the courſe of his term, to be reimburſed, the principal likewiſe; and which ſums added together, allowing for the decreaſe of intereſt, as the principal is paid off, I calculate to amount to 5s and 6d an acre per annum; which, ſuppoſing the rent to be 5s an acre when the farmers enter upon his farm, more than doubles it, from the time of improving, till the leaſe expires.

" I will now calculate the improvements and compare them; but before I do this, it will be neceſſary to remind you, that there are many lands where the clay or marle beneath the ſurface, is ſo intermixed with ſand, that there are many hundreds of loads carried that yield no improvement at all; another thing is, that ſuppoſing the marle, &c. good, yet if the carriage is long, or it is laid on ſhiftable fields, which are ſubjected to two crops, and a fallow, I am of opinion that in this caſe likewiſe it never pays half the expence; becauſe, being obliged to plough the clay or marle in directly, and continuing the common, it is ſunk and loſt before it ever incorporates properly with the ſoil; theſe failures, therefore, may fairly be laid at one fifth of the lands covered.

" To proceed to the calculation of the profits from the produce, I will throw the lands into the following courſe.

" Firſt, peaſe dibbled, or oats harrowed in, upon the flag with one plowing; ſecond, turnips; third, barley; fourth and fifth, layer for two years.

" Now as lands thrown into the above courſe, would by reſt, and taking only two crops of corn, and one of turnips, in five years, be in a ſtate of improvement without clay or marle; I can ſay the additional produce to each crop, on account of the clay, &c. (ſuppoſing it anſwers the farmer's wiſhes) only be as follows:

	£.	s.	d.
1. If with peaſe one comb, or if with oats, ſix buſhels per acre	0	12	0
2. Turnips per acre	0	4	0
3. Barley per acre, ſix buſhels	0	15	0
4. Layer per acre, firſt year	0	4	0
5. Ditto ſecond year	0	2	6
	1	17	6
Deduct 1-tenth for tithes	0	3	9
	1	13	9
The 5th of which is	0	6	9
But as 1-fifth of the claying fails of improvement, 1-fifth of this ſum muſt be deducted . . .	0	1	4
Extra profit on account of the clay, &c. per acre	0	5	5

" If I am right in the above calculation, (and if not I wiſh to be ſet right) a farmer who has a ſpirit to improve another perſon's eſtate, by clay and marle, may, in the courſe of a 21 years leaſe, get nearly all his money into his pocket again: but then you will ſay, that the great expence being over, he will have the advantage in the next leaſe; certainly, as he has had no advantage in the firſt term, his landlord can and ought to give him ſome in a ſecond; but there is no pull upon him, but honour and gratitude; and if the tenant is not in better luck than ſome folks I could name, he will find upon a new agreement, that he will have to pay very dear for improvements made wholly at his expence, or be obliged to turn his back and leave them.

" Yet far be it from me to ſuggeſt, that there are not ſome worthy characters, that have nobly and generouſly ſaid to a tenant at the expiration of a leaſe, " I know you have been at a very great expence in improving my eſtate, therefore go on and enjoy it at the old rent, ſo long as we both live." Two or three inſtances of this ſort have come within my own knowledge; I wiſh, for the encouragement of improvements in Agriculture, I could ſay 20 or 30.

" But ſuppoſe there were more inſtances, and a farmer was lucky enough to begin to improve a large tract of land, under one of thoſe worthy landlords, before a 21 years leaſe was expired; it is odds, but he might be dead, and his heir might be quite a different character; or, if as good a one, I am ſorry to ſay it, there are too many fools, nay knaves, they ought to be called, of farmers, that would endeavour to ſpoil him by going ſecretly, like a thief in the night, and offering all the rent that his induſtrious tenant has, with great toil and expence (which he is not again repaid) made it worth, and by ſo doing, bring it to what I obſerved above, that he muſt either pay a full rent for all his own improvements, or leave them to be enjoyed by a villain.

" From this unfair, unneighbourly behaviour, ariſes a double expence; for no ſooner is it known that A, has offered 50l. a year more for B's farm, and the latter unwilling to turn his back upon all his improvements, has given the advance offered, (for his landlord could not well refuſe him the firſt offer) then his neighbours in the pariſh begin with him; firſt, the overſeer puts 4s and 2d more into every poor's rate, which ſuppoſing them four or five ſhillings in the pound, as they are in many pariſhes, and daily encreaſing, ſay only 9l. a year, for them; then comes the ſurveyor, and calls for ſix days work more, with another team on the highways, which, if compounded for, is often 1l. 16s. more; but ſay, 1l. 7s. which is the leaſt; the 50l. advance is then got to upwards of 60l. to this muſt be added, the advance of tithes, which 19 times out of 20 is more in proportion than the advance of rent.

" The above, Sir, without dwelling any longer upon the ſubject, I ſhould think ſufficiently explains what I advanced, that there are too many obſtacles in the way, to make it prudent for a common farmer to improve by claying or marling, (wholly at his own expence, a large track of light lands on another perſon's eſtate, even upon a leaſe of 21 years; indeed it is my opinion, that it ſeldom anſwers in the firſt, and often fails in the ſecond leaſe, by a farmer's giving too great an advance of rent, rather than turn his back upon his improvements; for, if he is once led to give a little too much rent, he is next rated higher to the tithes, higher to the poor, higher to the church, and higher to the highways; in ſhort, there is no end that I can ſee, but utter ruin.

" I ſhould think, therefore, that it would be only fair and juſt, for gentlemen, afrer their tenants have laid out a thouſand pounds or upwards, (or leſs if the occupation is leſs) in improving their lands, to renew their leaſes at the ſame rent for 21 years, from the time the laſt years improvements was laid on, provided they went on with ſpirit and got through the whole in ſeven years, from the time of entering upon the farm; this, I muſt take the liberty to ſay, is the leaſt a gentleman can, or ought to do, to encourage a tenant, that has a ſpirit to improve his eſtate at his own expence.

" I would not have you or your readers think, that I write this paper to diſcourage improvements in Agriculture, quite the contrary; I believe it is well known, that I contradict ſuch an idea by my practice, all I aim at is, to lay what is termed the *ſaddle* upon the *right horſe*, by cautioning young ſpirited farmers to conſider a little, and have ſome good grounds to go upon, before they lay out great ſums of money upon another perſon's eſtate, and I wiſh at the ſame time, to give land owners a hint, that it is their duty, as well as intereſt, to aſſiſt their tenants in ſo expenſive an undertaking, as that of improving their light lands by clay and marle."

In addition to this we cannot help making another ſhort extract from the ſame gentleman, who obſerves, vol. I. p. 286, Annals, &c.

" From trials and obſervations I am clearly convinced that 7 cubic yards is the propereſt quantity to be laid upon an acre of land. If more be laid on, the longer it will be before it incorporates with the ſoil, and, of courſe, the longer before any benefit can be received.

" I once knew an inſtance where a farmer laid on 120 yards per acre, and after an expence which would have purchaſed the fee ſimple of the land, no benefit could be perceived.

" No pains ſhould be ſpared to break all the lumps, and get it fine by repeated harrowing and rolling, otherwiſe claying and marling ſeldom anſwer, where you go on with a courſe of ploughing in the old way.

" Little need be ſaid about the different quality of clay or marle, as every one muſt be content to uſe ſuch as is found on his premiſes.

" Clay that is freeſt from ſand, and marle that is ſoft and greaſy, are certainly the moſt valuable. And even blue clay that is condemned by moſt farmers I have found anſwer very well on light ſand; but they generally lie at too great diſtance from each other to be prudently got together.

" I have a ſcheme in agitation, on a ſmall ſcale, which I mean to execute, and which I expect to be very much condemned for; that is, to ſink a pit upon a ſtiff, clayey ſoil, and carry it about half a mile to light ſandy ſoil; to keep a ſtanding cart at both places, and take off as many loads from the ſurface of the latter and bring back: ſo that when I have clayed a few acres of land, I ſhall have ſanded about the ſame number of acres of clay land."

We can only beg pardon of Mr. Macro for the liberty we have taken in abridging his letter, as we do aſſure him it was a painful taſk to lop off a ſyllable from ſo uſeful a ſubject ſo well treated.

Our comments on theſe extracts would be uſeleſs, for they want no elucidation.

Did every gentleman feel ſo juſtly for that profeſſion to which he ſo honourably belongs, Agriculture would be improved; as the ſource of all great and expenſive improvements ſhould originate with the proprietor of land, and not with a tenant, who is here or there at the nod of his landlord.

Marle is unqueſtionably the moſt antient of natural manures, and well mixed and worked fine with the ſoil adds vigour to land of any kind, that has been exhauſted by cultivation. On paſture marle is likewiſe uſeful, provided it is of a good kind: the only way to enſure ſucceſs is, to make a ſmall experiment, as precepts cannot be infallible, and examples ſpeak for themſelves. The next on the liſt of natural manures is

CHALK.

Chalk is beneficial as a manure on ſtiff clays and ſand, as it is likewiſe on other ſoils, where it does not compoſe a part of the ſoil by nature. Chalk of the ſoft kind is beſt ſuited as manure for gravel or ſand, and that of the ſtony or hard kind will anſwer beſt on clay or ſtiff loam. Hard ſtony chalk is burnt into lime, ſimilar in quality to lime made from ſtone.

A gentleman of experience in Kent ſays, " In compariſon of chalk and lime, it is neceſſary I ſhould ſay my experience is in favour of chalk." As a further inſtance of the great eſtimation in which the Kentiſh farmers hold chalk, Mr. Young informs us " it coſts them 20s. per load by then they get it home: that they lay from 5 to 8 loads on an acre, either on a clover lay that it may be waſhed into the earth before it is ploughed, or on ſummer fallow; and that the effect is equal to the beſt rotten dung, and laſts 15 or 20 years. On loam it anſwers the beſt: in fact, he ſays it performs wonders. This is certainly valuable information for thoſe who have it in their power to procure chalk, and are ignorant of its value as manure. We are now led to an article little known as a manure; namely,

LIMESTONE pulverized.

Limeſtone broke into ſmall pieces certainly adds fertility to ſeveral kinds of ſoil, as clay, loams which have not previouſly a mixture of ſmall ſtones or pebbles, and alſo a ſandy loam without ſtones.

The method of enriching lands by means of ſtone chippings is mentioned by Doctor Plot in his " Hiſtory of Oxfordſhire," as a cuſtom in common uſe in ſome parts of the country; which deſtroys all doubts of its antiquity. The effect of ſtones promoting vegetation on cloſe ſtiff lands may be rationally accounted for, without even admitting they poſſeſs any alkaline quality. In the firſt place, ſoil with a mixture of ſmall round ſtones is preferable to one of the ſame kind without any: this hypotheſis we believe is invariable. The reaſon of ſuch an effect in ſtones we apprehend proceeds from their breaking and dividing cloſe ſoils, thereby giving room for the roots of plants to ſtrike; and as they render the texture of the land more looſe, the ſun and air have an eaſier admiſſion, and conſequently their benign and fertilizing influence have the power of acting with the greater force.

Where coals are expenſive, and other firing ſcarce, lime is a very chargeable manure. We have not the leaſt doubt but lime ſtone beat ſmall would anſwer every purpoſe of lime, particularly on ſtiff, cold land: ſhould this be the caſe, a valuable ſource for manure lies unexplored; as the breaking and preparing ſtones for lime is attended with an heavy expence, breaking them ſtill ſmaller would not be a material addition. But this being ſpeculation, as we have never known it tried, we hope the reader will judge for himſelf, and excuſe the hint we have given; and we will introduce a manure which has been tried with the greateſt ſucceſs: this is Limestone reduced to powder in a turnpike road. This, as a manure, was introduced to practice by Mr. Richard Davis of Kiteborough, near Morton in Glouceſterſhire, between 30 and 40 years ſince. The ſoil of his farm was of a hollow, cold, loamy nature, ſubject to grow furze and a long coarſe graſs, and very uncertain for corn. Thinking the ſoil wanted ſomething to give it firmneſs, he carted the cleanings from a limeſtone turnpike road (which runs parallel with his farm) upon a ſummer fallow for wheat, about 30 cart loads to an acre. The ſucceſs which attended this firſt effort was beyond his moſt ſanguine expectation, and was a ſufficient ſtimulative for him to proceed. The ſhovelings, or cleanings of the road, which had, from the time of its being firſt made a turnpike, been throwed by the road ſide as uſeleſs, were ſoon conveyed by Mr. Davis upon his farm, and their effect was much greater than the beſt horſe dung. One year in particular he carried ſomething more than 1000 loads on a piece of fallow of about 15 acres, and the reſult was equal to the quantity. Four quarters of oats upon an acre previous to the diſcovery of this improving manure were deemed a good crop, but ſince he has had 8 or 9 quarters upon an acre. Theſe improvements have not been confined to arable lands alone, but have been found equally beneficial to meadow and paſture, as it produces white clover, and other ſweet herbage, where the moſt rough and ſour graſs grew before.

It is neceſſary to remark, that the lime ſtone of which we are ſpeaking is ſoft in its nature, by no means of a proper ſubſtance to make roads; but upon the road we are noticing it is *Hobſon's choice*, that or none. After theſe ſtones are laid and broke upon the road, if rain follows very ſoon, the heavy carriages which paſs, quickly reduce them to the conſiſtence of a very ſoft mud, which is raked or ſhovelled off, and is as a manure ſuperior to any thing which can be procured. To uſe it generally on all kinds of ſoil, it might not be equally efficacious, as on the hollow wet land we are mentioning; but we have every reaſon to believe it would anſwer a very good purpoſe on any kind of ſoil, as we have known it tried ſucceſsfully on ſeveral.

On a rich ſtrong loam in particular it has a very good effect; and with one fourth of good mould it will produce cabbage of a very large ſize; theſe we imagine are proofs of its general utility as an excellent manure.

Mr. Davis, the gentleman who has the credit of firſt uſing the cleanings of a lime ſtone road as a manure, has acquired a very conſiderable fortune, and with pleaſure attributes no ſmall ſhare of his great ſucceſs to the diſcovery; he is now retired from buſineſs, and enjoys the reward of his integrity and induſtry; making himſelf a uſeful member of ſociety, unambitious of any other diſtinction than that of an Engliſh farmer.

As with marle, the ſame care ſhould be taken with lime ſtone road cleanings, to mix it well with the ſoil; ſowhich purpoſe, it is a good method to ſpread it on clover, or other graſſes, ſome months before they are ploughed for corn; the rains waſhing it into the earth makes it incorporate, more intimately with the ſoil. Otherwiſe on fallows, when they are clean from weeds and worked fine. Winter being the ſeaſon roads want cleaning; what is thrown in winter or ſpring may be carried and ſpread upon paſture, and meadow the following autumn; as the winter rains will waſh it into the earth before ſpring, and the land receive benefit in the ſummer. Let it be noticed, that the virtues of this manure are not exhaled by the air and ſun, like animal and artificial manures.

Should any doubt ariſe, or the foregoing account prove unſatisfactory, we are of opinion, the gentleman who has uſed it with ſuch ſucceſs would willingly give his ideas to any gentleman on the ſubject with pleaſure. This leads us to

MUD.

Mud is of different kinds and qualities, according to the ſource from whence it is collected; if the drainings of yards, or the waſhings of rich ſoils run into ponds, or ſlow running brooks, the mud or cleanings are valuable. And if from barren hills or poor unmanured clays, its virtues are not of much conſequence. Mud ſhould be thrown out of ponds and brooks a conſiderable time before it is uſed, and mixed in compoſt with lime is reckoned the moſt advantageous way of uſing it on land; or if aſhes made from either coal or wood can be procured, they may be mixed with mud to a good purpoſe.

As this is the reſult of univerſal experience, we by all means recommend it to the practice of thoſe who have it in their power to procure mud to mix to it with lime, or aſhes.

When it has lain in compoſt a few months, it will be found an excellent manure for paſture or arable, and the poorer the ſoil, the greater will be the advantage. We will now conſider the virtues of

COMMON SALT.

The Scotch Encyclopædia pronounce ſalt ineffectual, as a manure, which we deny! As experience, the moſt ſatisfactory of all evidences, proves the contrary.

Common ſalt loaded with the heavy duty government have at different times laid upon it, is ſo expenſive an article, that its virtues muſt be great indeed, to compenſate for the expence, if uſed as a manure. But there is a cheaper kind to be obtained, at all places where ſalt is made, which is the cleanings of the pans or oilers, and called foul ſalt, and is an incruſtation of the ſalt to the ſides and bottom of the pan, occaſioned by the heat of the fire. This is ſold very reaſonable, and is always attended by an officer to ſee that it is made uſe of as manure only. It has been uſed round *Droitwich in Worceſterſhire* as manure, as long as ſalt has been made there, and with ſucceſs: to proportion the quantity to the ſoil ſhould be attended to with care, as too large a quantity is very injurious. The following communication of R. Legrand, Eſq. to Mr. Young, Annals, &c. Vol. 5. p. 149. contains a decided proof of the efficacy of ſalt.

" HAVING tried it upon a ſmall ſcale, upon a ſandy ſoil, I can aſſert ſixteen buſhels to be a proper quantity for one acre: it gradually advanced in its effects to 16, and as gradually diminiſhed to 40 buſhels, when vegetation was deſtroyed.

" Twice only have I had an opportunity of buying a few tons of foul ſalt, and uſed it both times upon a barley tilth; ſowing the ſalt immediately after the barley, the event was perfectly ſatisfactory.

" The verdure in the ſpring exceeded any thing of the kind I ever ſaw, and the ripened appearance was whiter by many ſhades than I ever beheld.

" N. B. Salt is noxious both to weeds and vermin."

If ſalt is uſed on paſture it ſhould be mixed well in compoſt, with mud, or loamy earth, 15 or 20 loads of earth to one of ſalt, and turned in the heap two or three times to incorporate it properly. This compoſt ſhould be laid on and ſpread in autumn; a common mould dreſſing will be ſufficient, and there are few kinds of ſoil but will be benefited.

GROWING VEGETABLES.

It has been cuſtomary in many places, particularly in England, to ſow buck-wheat, vetches, &c. and then to plough them in for manuring the land: this being ſimilar to that operation of nature by which ſhe renders the uncultivated ſoils ſo exceedingly fertile, cannot fail of being attended with ſingular advantages; and might be looked upon preferable even to laying dung on the land to fatten it, was it not attended with the entire loſs of a crop for that year.

Where manures cannot be obtained, and on outlying lands, ploughing in thoſe ſucculent plants is certainly good management. Before ſuch management is attempted, the ſoil ſhould be cleaned from weeds, and after the crop is buried ſhould be rolled with a heavy roller, which will be the means of facilitating fermentation.

This method will anſwer on any kind of ſoil, and ſhould be put in practice in the following manner. Sow winter tares or vetches in autumn, and mow or eat them off the ſpring following; and immediately, on one ploughing, ſow buck wheat, which plough in and roll, and the land will be in excellent condition for wheat, or the more ſo for barley the next ſpring.

ONE SOIL USED AS MANURE ON ANOTHER.

The cloſe texture of clay, and the looſe and friable nature of ſand, form a contraſt in the nature of ſoils, by no means friendly to vegetation: when thoſe oppoſites are united, the ſoil becomes more fertile, and when blended with native or vegetable mould, is further improved.

Thus clay is conſidered as a manure to ſand, and on the contrary ſand to clay. The reſult of mixtures of this kind cannot be defined, nor aſcertained on paper; to experiment we muſt refer the Agriculturiſt for ſatisfaction.

As thoſe ſoils are ſeldom found very near each other, improvements are not to be effected, without expence and difficulties which a prudent man would be afraid to encounter with.

Although there are thoſe formidable obſtacles in the way, improvements of the kind are often practicable; and a ſpirited perſeverance performs wonders.

Clay is generally found more beneficial on ſand, than ſand on clay. Clay enriches a ſandy ſoil, by giving it body or firmneſs; and ſand in clay by breaking its toughneſs. Clay is alſo uſed with ſucceſs on ſome gravelly ground; but there are ſome kinds of clay and gravel, which will not unite; this happens when the ſoil conſiſts of ſmooth round pebbles, and a ſmall portion of mould.

Loam is a manure on any ſort of land, provided the ſoil you manure with is not inferior to that you intend to manure.

When land has been exhauſted by long continued cultivation, freſh mould from under hedges, the ſides of roads, or other places, where it is to be procured, ſurprizingly fertilize and refreſh the ſoil.

SHELLS.

The perpetual fertility of calcareous earth, ſo confidently mentioned in the Scotch Encyclopædia is a phenomenon in Agriculture, with which we are unacquainted, and can only inform our readers by an extract from that work, viz.

" In all ſeaſons it produces the moſt luxuriant herbage, and never got any manure ſince the creation, and has been from time immemorial ſubject to the following courſe of crops:

" 1. Bear, after once ploughing from graſs, uſually a good crop.
" 2. Bear, after once ploughing, a better crop than the firſt.
" 3. Bear, after once ploughing, a crop equal to the firſt.
" 4. 5. and 6. Natural graſs, as cloſe and rich as could be imagined, might be cut, if the poſſeſſor ſo inclined, and would yield an extraordinary crop of hay each year.

" After this the ſame courſe of cropping is renewed. The ſoil that admits of this ſingular mode of farming appears to be a pure incoherent ſand, deſtitute of the ſmalleſt particle of vegetable mould; but, upon examination, it is found to conſiſt almoſt entirely of broken ſhells: the fine mould here bears ſuch a ſmall proportion to the calcareous matter, as to be ſcarce preceptible, and yet it forms the moſt fertile ſoil that ever we yet met with."

OBSERVATIONS.

This is a miraculous ſoil, and if the fact is as related, places ſhells and other calcerous ſubſtances before every other manure, in as great a degree as the ſun exceeds the moon in brilliance.

Manures being the grand ſupport of Agriculture, we have went rather fully into the nature of thoſe we deemed moſt uſeful, and upon the whole have noticed all that are in uſe, as far as our experience and obſervation led us.

SECT. III.

WHEAT AND ITS CULTIVATION.

WHEN we are mentioning Wheat, our ſubject may be juſtly deemed, of the firſt importance, it being on what is very emphatically called the " STAFF OF LIFE." In the firſt place we propoſe conſidering the preparation of the ſoil for the growth of Wheat, — the different kinds in uſe, — the time of planting, — the various methods of planting or depoſiting the ſeed in the earth, — the caſualties or diſeaſes to which Wheat is ſubject; — with a few other obſervations.

Wheat ſhould be planted on land that is freſh, and in good heart; there is no preſcribed rule what crop it ſhould follow, although it is a general maxim with farmers not to let Wheat and Barley follow each other; and we believe the prohibition is founded on experience; as exhauſting crops ſhould not ſucceed each other.

AGRICULTURE.

To ſummer fallow for Wheat is an old practice, and certainly a good practice on cold ſtiff land, yet the cuſtom of ſowing Wheat on fallow may be varied, by letting the fallow lie all winter, and ſow Barley in the ſpring; after Barley, Beans; and the Wheat crop ſucceed the Beans; but this, although called good huſbandry, we by no means think equal to ſowing Wheat on fallow, Beans next, and then Oats or Barley with Clover, and Wheat again on the Clover lay.

This we call a round of management on land which will not bear Turnips; but it is contrary to the opinion of thoſe gentlemen who call themſelves anti-fallowiſts, who contend that Beans, Peaſe, Vetches, or Clover, anſwer the purpoſe of fallows; in ſome reſpects they may; but be aſſured they will not keep land clean, particularly from Couch graſs.

Let it be underſtood, that with thoſe meliorating crops, as they are called, drilling and horſe-hoeing is to be purſued; but how drilling and horſe-hoeing are in all ſeaſons to be effected on ſtiff clay, or ſour tough loam, is the queſtion? The diſcuſſion of this matter muſt be when we treat of Ploughing, &c.

If fallows can be aboliſhed on ſtiff land, the Wheat crop will of courſe follow Beans or Clover; but how drilling can be performed on this kind of ſoil, on a Clover lay, and as autumn ſeaſons are very precarious, is a circumſtance beyond our experience or obſervation.

When clover is intended to be ſowed wheat, plough the land, and let it lie three, four, or more days to dry (that is on low, wet land) before you ſow the ſeed, which will make the harrows perform their work better, and the ſeed will be better covered, and not be ſo ſubject to matt or burſt in the ground, a circumſtance which frequently injures the crop: be alſo careful to plough the furrows narrow.

On hill land, and other, that will bear turnips, and permit them to be eat off in a proper manner, wheat is either ſowed on clover, or rye graſs and clover, or according to the drill management on potatoe fallow: where potatoes are properly cultivated, this is certainly a valuable and improved branch of huſbandry, and muſt get land in fine condition for wheat.

The kinds of wheat are *Cone* and *Lammas*; the cone with a beard like barley, and the Lammas ſmooth in the head: theſe ſeem the only ſorts where the diſtinction is ſo viſible; but they are branched into a variety of ſorts, bearing a ſimilitude in appearance to either Cone or Lammas.

Red Lammas is the wheat of that kind moſt generally ſowed on hill and vale, and had no other kind of lammas wheat been known, we do not know the loſs would have been material.

There is a variety of other ſorts of lammas wheat, as yellow, white, &c. ſowed in different countries, and frequently changed from curioſity or experiment, generally with great expectations at firſt, which ſeldom laſt long.

The Cone, or bearded wheat, in general cultivation, is commonly ſowed on ſtrong rich land, generally in vales on ſtrong loam, where its produce is very great; and being ſtrong and large in the ſtraw, is not ſo liable to fall down by wet weather on the approach of harveſt.

There is often an advantage on high lands, where the ſoil is good, in ſowing Lammas and Cone Wheats, mixed about one third Cone. We have obſerved often great benefit from this method, as where one half of a ground has been ſowed with mixed wheat, and the other lammas alone, the mixed has been much ſuperior both in quantity and quality.

There is another kind of wheat lately introduced, or rather revived, in this kingdom, quite different in its nature to thoſe in general uſe: this is called ſpring wheat. it is of the beard or Cone kind, and inſtead of being ſowed in autumn, is not ſerved till ſpring: great advantages were expected when firſt this kind of wheat was announced; but a few experiments convinced thoſe who made them, that ſpring wheat was not adapted to this climate, at leaſt that barley, oats, or other ſpring corn, were preferable to ſpring wheat.

Mr. Young has lately introduced a kind of Wheat, which he calls *Velvet Wheat*; and remarks upon it, that it is very promiſing to become an acquiſition: ſhould that be the caſe, it cannot be in better hands to diſtribute it; and we ſincerely wiſh Mr. Young on this, as on every other occaſion, the greateſt ſucceſs.

The times of ſowing Wheat differ very materially; on the hills and rocky land, they begin ſowing the latter end of July, if the weather permits; and it is no uncommon ſight to ſee a perſon have two crops of Wheat of different years, growing at the ſame time.

This early ſeeding is moſtly on a rye-graſs and clover, ſward of two years, or on ſaintfoin breaſt ploughed and burned, and give the Wheat ſufficient ſtrength to endure the winter, as, before the froſts are ſevere, you will ſee the Wheat matted together on the land.

The Wheat ſeeding on thoſe hills is generally finiſhed before the middle of September, provided the weather ſuits, as particular regard is paid towards the land being ſufficiently wet, if that is not the caſe it renders the crop hazardous.

In the vales and low lands, in general on fallows, Wheat ſowing begins about the middle of October, and continues till Chriſtmas; the latter Wheat ſowing is generally prolonged by too much wet weather, as the early is by dry.

The quantity of Wheat generally ſowed on hill land, and ſowed early, is from two and a half to three buſhels per acre. On low or vale land not ſo much, the general quantity being about two and a half buſhels if ſowed in October, and two buſhels or ſomething leſs if in November or later in the ſeaſon; as early ſowing ſkould not be ſowed dry, ſo the later feeding ſhould be wet.

Spring Wheat is generally ſowed in April, or the beginning of May.

Attempts at improvements are certainly laudable and praiſeworthy; and the man who renders ſervice to the art of Agriculture, is a real friend to his country; but new inventions are generally introduced with ſuch zealous and poſitive aſſurances of ſucceſs, that the great theoretic promiſes which are previouſly made, always fall ſhort when put in practice.

Were improvements brought forward with more diffidence, we are of opinion general practice would ſooner follow, if the invention merited public attention.

Setting of Wheat is a practice recently brought into uſe, and in all probability is a method deſerving public attention; as we have never ſeen it in extenſive practice, we beg leave to lay the following before our readers.

Setting of Wheat, a method which is reckoned one of the greateſt improvements in huſbandry that has taken place this century. It ſeems to have been firſt ſuggeſted by planting grains in a garden from mere curioſity, by perſons who had no thought or opportunity of extending it to a lucrative purpoſe. Nor was it attempted on a larger ſcale, till a little farmer near Norwich began it about 17 years ſince, upon leſs than an acre of land. For two or three years only a few followed his example; and theſe were generally the hurt of their neighbours merriment for adopting ſo ſingular a practice. They had, however, conſiderably better corn and larger crops than their neighbours: this, together with the ſaving in need, engaged more to follow them: while ſome ingenious perſons, obſerving its great advantage, recommended and publiſhed its utility in the Norwich papers. Theſe recommendations had their effect. The curioſity and inquiry of the Norfolk farmers (particularly round Norwich) were excited, and they found ſufficient reaſon to make general experiments. Among the reſt was one of the largeſt occupiers of lands in this county, who ſet 57 acres in one year. His ſucceſs, from the viſible ſuperiority of his crop, both in quantity and quality, was ſo great, that the following autumn he ſet 300 acres, and has continued the practice ever ſince.

This noble experiment eſtabliſhed the practice, and was the means of introducing it generally among the intelligent farmers in a very large diſtrict of land; there being few who now ſow any wheat, if they can procure hands to ſet it.

It has been generally obſerved, that although the ſet crops appear very thin during the autumn and winter, the plants tiller and ſpread prodigiouſly in the ſpring. The ears are indiſputably larger, without any dwarfiſh or ſmall corn; the grain is of a larger bulk, and ſpecifically heavier per buſhel than when ſown.

The lands on which this method is particularly proſperous, are either after a clover ſtubble, or on which trefoil and graſs-ſeed were ſown the ſpring before the laſt. Theſe grounds, after the uſual manuring, are once turned over by the plough in an extended flag or turf, at two inches wide; along which a man, who is called a *dibbler*, with two ſetting-irons, ſomewhat bigger than ram-rods, but conſiderably bigger at the lower end, and pointed at the extremity, ſteps backwards along the turf and makes the holes about four inches aſunder every way, and an inch deep. Into theſe holes the droppers (women, boys, and girls) drop two grains, which is quite ſufficient. After this, a gate buſhed with thorns is drawn by one horſe over the land, and cloſes up the holes. By this mode, three pecks of grain is ſufficient for an acre; and being immediately buried, it is equally removed from vermin or the power of froſt.

The regularity of its riſing gives the beſt opportunity of keeping it clear from weeds, by weeding or hand-hoeing.

Wheat-ſetting is a method peculiarly beneficial when corn is dear; and, if the ſeaſon be favourable, may be practiſed with great benefit to the farmer.

Sir Thomas Beevor of Hethel-Hall in Norfolk, found the produce to be two buſhels per acre more than from Wheat which is ſown; but having much leſs ſmall corn intermixed, the ſample is better, and always fetches a higher price, to the amount generally of two ſhillings per quarter.

This method, too, ſaves to the farmer and to the public ſix pecks of ſeed-wheat in every acre; which, if nationally adopted, would of itſelf afford bread for more than half a million of people.

Add to theſe conſiderations, the great ſupport given to the poor by this *ſecond* harveſt, as it may be called, which enables them to diſcharge their rents and maintain their families without having recourſe to the pariſh.

AGRICULTURE.

The expence of ſetting by hand is now reduced to about ſix ſhillings per acre; which, in good weather, may be done by one dibbler, attended by three droppers, in two days. This is five ſhillings per day; of which, if the dibbler gives to the children ſixpence each, he will have himſelf three ſhillings and ſixpence for his day's work, which is much more than he can poſſibly earn by any other labour ſo eaſy to himſelf.

But put the caſe, that the man has a wife who dibbles with him, and two or three of his own children to drop to him, you ſee his gains will then be prodigious, and enough to enſure a plenty of candidates for that work, even in the leaſt populous parts of the country.

It is, however, to be obſerved with regard to this method, that in ſeaſons when ſeed-corn is very cheap, or the autumn particularly unfavourable to the practice, it muſt certainly be leſſened. In light lands, for inſtance, a very dry time prevents dibbling; as the holes made with the inſtruments will be filled up again by the mould as faſt as the inſtrument is withdrawn. So, again, in a very wet ſeaſon, on ſtrong and ſtiff clays, the ſeeds in the holes cannot be well and properly covered by the buſhes drawn over them.

But theſe extremes of dry and wet do not often happen, nor do they affect lands of a moderately conſiſtent texture, or both light and heavy ſoils at the ſame time, ſo that the general practice is in fact never greatly impeded by them.

The ſetting of wheat certainly is an invention of utility on rich ſtrong land, which has ſtrength ſufficient to nouriſh a number of ſtems or ſtraws from the ſame root.

Setting may be performed on a ſoil, and in weather in which drilling is impracticable; but where a real uſeful and commodious drill can be uſed, a very material ſaving in the expence will be made, certainly an object of conſequence to a farmer.

Improvements in the planting of Wheat go ſtill further; *dividing and tranſplanting the roots* has been practiſed: an account of which has been publiſhed in the Philoſophical Tranſactions, and likewiſe by the Rev. Mr. PIKE, of Edmonton, in his correſpondence with Mr. Young; as a rational and pleaſing amuſement; and at the ſame time inveſtigating the works of nature, theſe experiments do honour to thoſe who make them; and communicating them to the public, is gratifying the curious.

As an acquiſition to Agriculture, we cannot rank the tranſplant of Wheat, as ſo tedious a proceſs can never become uſeful.

As vegetables, like animals, are ſubject to diſeaſes, the principal maladies which affect Wheat, are ſmut and mildews. Smut is a diſeaſe very injurious to a crop of Wheat in every other reſpects fair and promiſing; the grains which are affected with the ſmut, inſtead of being filled with the natural mealy ſubſtance, contains a black powder, like lamp black of a very diſagreeable ſmell, which by the operations of thraſhing and grinding, communicates its diſagreeable properties to the bulk.

Dr. Home, in his Principles of Agriculture and Vegetation, claſſes the *ſmut* in grain among the diſeaſes ariſing from this cauſe. He is of opinion, that too great an abundance of juices in a vegetable will produce diſeaſes ſimilar to thoſe occaſioned by repletion in animal bodies; viz. ſtagnations, corruptions, varices, carioſities, &c. along with the too great luxuriancy we have juſt now mentioned, which he expreſſes by "too great an abundance of water-ſhoots." Hence he is induced to claſs the ſmut among diſeaſes ariſing from this cauſe; it being a corruption happening moſt in rainy ſeaſons, and to weak grain.

Like other contagious diſeaſes, he tells us, the ſmut may be communicated from the infected to healthful grain.

As a preventative, he recommends ſteeping the grain in a ſtrong pickle of ſea-ſalt.

Beſides the effect which this has upon the grain itſelf, it is uſeful in ſeparating the good from the bad; the beſt ſeed falling to the bottom, and the faulty ſwimming on the top of the liquor.

For the ſame purpoſe, a ley of wood-aſhes and quicklime is recommended by ſome; and, by others, a ſolution of ſaltpetre or copperas; after which the grain is to be dried with ſlacked lime.

How far Dr. Home may be right in his conjectures on the cauſe of ſmut, we cannot determine, opinions on the ſubject being ſo various; but his prevention is according to the prevailing practice.

A ſtrong lye or lixivium is the remedy in general uſe, and Mr. Andrews an ingenious gentleman, who correſponds with Mr. Young, gives the following receipt:

"Make half a hogſhead of ſtrong lye from wood aſhes, put it into a boiler, and add 7lb. of common ſalt, and half a pound of arſenic; boil it in a copper about five minutes, which will ſo far take off the poiſonous quality of the arſenic, as to prevent its deſtroying fowls, or birds, ſhould they pick up any of the uncovered ſeeds, after the lye is boiled put it into a tub, (an old wine pipe will make two) and let it ſtand till cold; then get a ſtrong cloſe made baſket, that will hold about two buſhels, and ſet in the lye, put half a buſhel of wheat into the baſket at a time, ſtirring it, and ſkim off the light grains that ariſe; then take it out of the lye, and ſpread it on a floor, and mix as much quick lime powdered as is neceſſary to prepare it for ſowing; you may prepare a quantity three or four days before it is wanted. The quantity of lye will ſwim about 50 buſhels Wheat."

Mr. Young has tried this lixivium himſelf, and from experience thinks it preferable to any other, as he is of opinion the arſenic is particularly efficacious.

A ſteep or brine may be made with ſoap-lyes, with a mixture of one half water, otherwiſe the hands of the ſeedſman will be injured.

Chamber lye may be ſaved, and the brine in which meat has been ſalted and mixed together; with the addition of ſalt and water, ſhould the quantity be inſufficient for the purpoſe: it will be of further ſervice, indeed it is neceſſary to let the Wheat ſteep all night, by which management it grows much ſooner: and it is a general received opinion, that it makes it grow more kind and ſtrong.

From experience and obſervation, as alſo from the opinion of that excellent cultivator, Mr. Macro, we think the great benefit of ſteeping Wheat ariſes from the opportunity it gives of taking the light unhealthy grains from the quantity; added to which, that the ſaline mixtures which are uſed tend to ſtrengthen and promote the growth in its firſt ſtate, and to protect the root of the plant from the ſeverities of the weather.

Good ſound ſeed, which grew on land of a different and oppoſite kind of ſoil to that on which you intend to ſow it, certainly in ſome degree, prevents ſmut; for we have been witneſs frequently to the ill effects which attend the ſowing ſeed too often on the ſame kind of land.

Another diſeaſe to which Wheat is liable is the mildew, which appears on the ſtraw in black ſpots, and ſometimes inclining to yellow: this generally attacks the Wheat when it approaches towards ripening.

We have never ſeen the mildew on wheat, and other grain, accounted for on ſuch familiar and rational principles as by Mr. John Jenkinſon, in his Letter to Mr. Young on the ſubject.—Vide Annals, &c. vol. III. p. 318.

ON THE MILDEW.

By Mr. JOHN JENKINSON.

"THE mildew in grain is a very bad diſorder, and I am afraid an incurable one; ſituation and early ſowing may in part, and ſometimes wholly prevent the evil. In ſome places, not one year in ten thin Wheat eſcapes it; and often then other grain is affected.

"For many years I have thought, and obſervation and experience every year confirm it, that the mildew is nothing more or leſs than the ſtoppage of circulation in the plant, and as the grain grows near ripe, the circulation becomes more languid, which makes it at that ſtage more liable than any other to be ſiezed with the diſorder.

"In this northern part of the nation, I have obſerved froſt to be the moſt general cauſe of the malady; and ſometimes wet ſtormy weather. Some people are of opinion, that a thick glutinous matter which ſometimes falls in the night, and what is commonly called *a honeyfall*, which, not being ſoon expelled by the ſun, will bring it on. This cauſe is from hence ſuppoſed, to derive its name; but, for my own part, I never obſerved the mildew proceed from this cauſe

"When it proceeds from froſt, and the mildew is only partial, then low hollow places, and ground much confined only ſuffer; the reaſon is, in hollow and confined ſituations the vapours are in greater quantities, which being condenſed by the cold, and falling on the grain, congeal the juices of the plants which ſtagnate, and, according to the degree, become more or leſs affected.

"When the grain is near ripe, as obſerved before, it is ſooner affected than when freſher; but then the damage is not ſo great as when it takes place when the grain is farther from maturity.

"When the froſt is attended with a thick fog, which is not uncommon in the latter part of ſummer, then almoſt inevitable deſtruction enſues. The fog preventing the rays of the ſun from taking effect as they otherwiſe would.

"The mildew, laſt year, was almoſt general in this part, which aroſe from froſt, accompanied with a cold ſtrong north wind. The year before it was occaſioned by a few days of wet, cold, ſtormy weather, and ground with a north aſpect was moſt ſubject to the diſorder; but wheat being moſtly cut, only the late ripe was affected, ſo that the injury to the wheat crop was in no comparison to this laſt year.

“ On the contrary, laſt year, the oats being moſtly green, were very little, if any, affected along with the wheat; but the year before, the oats being nearer at hand, were materially injured.

“ An acquaintance of mine, a little before laſt harveſt, and ſeveral days before the general ſtorm took place, went 15 or 16 miles north of Kendal, which you know is at the foot of the mountains. A little north of the town he beheld a fine field of Wheat, which he told me he viewed with pleaſure.

“ The perſon returned in two or three days at fartheſt, and the whole field, except a little riſing ground near the middle, was ſtruck with the mildew, which greatly ſurpriſed him; but, on my deſiring him to recollect what nights they had in the fells, he readily called to mind, that they were very cold, with a ſharp froſt. Upon the riſing ground, the ſun had relieved the plants before their deſtruction, and very probably the congealed vapours were not quite ſo denſe in that part.

“ The mildew affects the grain like a mortification in the human frame, becomes full of little black places, and of conſequence brings on a premature death.

“ I am yours, &c.

“ J. Jenkinson.”

The cauſe of the mildew in Wheat is in all probability occaſioned by froſts in the ſpring, which cauſes a ſtagnation of the vegetable juices; the ſoil being ſoaked by wet, and froſt immediately ſucceeding, has a greater effect than if the ſoil was dry, for this reaſon, a dry ſpring is always kind for Wheat.

A thin crop of Wheat is more apt to mildew than one which is thicker, as thoſe caſual froſts find a more ready admiſſion by the ground not being ſo well defended.

If the mildew happens, through the too hollow texture of the ſoil, the land ſhould not be too often ploughed, previous to its being ſowed Wheat, likewiſe eating it off, and treading in ſpring, may be of ſervice as a preventative.

Land, which is ſubject to mildew Wheat, renders the crop very precarious, as it very ſeldom eſcapes; it is therefore neceſſary for a farmer to be very circumſpect in his enquiries in this reſpect before he enters upon a farm to which he is a ſtranger.

Let it be particularly noticed, that ſteeping of Wheat effectually prevents its deſtruction by inſects in autumn.

OBSERVATIONS.

Reſpecting the growth of Wheat, nothing ſhould be neglected either in reaſonable expence or labour, to procure good crops of Wheat; at the ſame time the return which expence and induſtry require, ſhould be kept in view; for that man is the beſt farmer who obtains the greateſt crops of corn at the leaſt expence; for little does it avail to get 40 buſhels of Wheat or upwards, upon an acre, if the expence has been greater than the return will be.

To riſque Wheat or Barley on land, which is foul with weeds, or poor in condition, is bad management; ſeed and expence are nearly the ſame; and the greateſt good fortune of ſeaſons and other circumſtances will only bring forth a ſaving crop, and the land is doubly exhauſted.

The management of Wheat at the time of harveſt is generally known, and pretty uniformly purſued throughout the kingdom; there is one error we would wiſh to point out to the public, which is the cuſtom of letting Wheat, and indeed all kinds of corn, grow too long in the field before it is cut.

By this means if wet ſucceeds the grain is ſtained and diſcoloured immediately, and will quickly grow in the ſheaf: whereas if it is cut juſt as it begins to bend the head, and while a few of the ſtraws retain ſome of their green appearance, and tied up in ſmall ſheaves, it will ſtand in the field a conſiderable time, and neither grow nor looſe its colour.

In oppoſition to this, we may be perhaps told that corn cut green will not thraſh ſo eaſy; it may not perhaps; but we will venture to aſſert, that one penny per buſhel will make up the deficiency, which the ſuperior colour of the grain will doubly repay.

This being the reſult of experience, we communicate it as ſuch, and are confident it merits attention; and next conſider

SECT. IV.

BARLEY AND ITS CULTIVATION.

BARLEY is the grain, next to Wheat, in general utility; and is ſufficiently known to need any deſcription: like Wheat, Barley is an exhauſting crop; for that reaſon they ſhould not follow each other.

Land, which will bear good turnips, and permit ſheep to eat them off in the winter is generally kind for Barley; but that is a rule to which we can make an exception, as a ſandy loam, without a mixture of ſtones, ſeldom or never bears Barley of a good body or colour, there is generally ſtraw plenty, but the corn indifferent, and this ſoil turnips well.

The ſoil which grows Barley to the beſt advantage, is a harſh, ſtone loam, and after a crop of turnips ſeldom diſappoints the expectation.

The ſort of Barley ſowed on turnip land is generally the long eared Barley, which ripens early.

There is a cuſtom prevails of procuring ſeed from Patney, in Wiltshire, and the Iſle of Thanet in Kent, which, according to the popular notion yields its produce earlier in ſeaſon, than Barley brought from any other place, although the change of ſoil be equally good: this idea experience, in ſome inſtances, has been in favour of, and in others no difference has appeared.

From thoſe proofs on each ſide the queſtion, it may be reaſonable to conjecture, that when perſons go to the extra price of this far fetched ſeed, to inſure ſucceſs, they plant it on the beſt manured and more promiſing ſoil, that their hopes may not be diſappointed: this accounts for its being fit to harveſt a week ſooner than the other parts of the crop.

On the advantage of ſowing Barley early, we cannot preſent the public with a more exact ſtatement of circumſtances than that given by the Right Honourable the Earl of Orford, to Arthur Young, Eſq. Vide Annals, Vol. IX. p. 385.

ON THE TIME OF SOWING BARLEY.

By the Earl of Orford.

“ THE common management of the turnip huſbandry in Norfolk has this evil in it, that the crop is kept feeding ſo late in the ſpring, that ſucceeding barley often ſuffers conſiderably, ſometimes to the amount of the value of the turnips.

“ To aſcertain what would be the effect of much earlier ſowing than is ever practiſed here, I made the following experiments upon a ſandy or an imperfect chalk bottom, but deep, and worth about ſeven ſhillings an acre.

1785.

“ Twenty-three acres of turnips being fed off in time, were ribbled, that is, half ploughed, on to four-furrow ridges, ſowing the barley 3½ buſhels an acre, the 7th of February, in the manner of Wheat ſown on the ridge. Sharp froſts, with and without ſnow, followed the ſowing, and the ſeed laid five weeks before it appeared; but the crop received injury. It was reaped. The produce, five quarters, one buſhel, and one peck per acre; a very good and ſhort ſample.

“ I threw the land on a ridge work, for three reaſons; 1. Becauſe it promiſed to preſerve the plants dryer in caſe of much wet weather; 2. To afford the hares, which abounded very much here, eaſy paths, to prevent their making others acroſs the lands; 3. To have the power of ploughing the furrows with a broad double-winged ſhare, to anſwer the purpoſe of horſe-hoeing.

1786.

“ Fourteen acres were this year cultivated exactly as in the preceding. The turnips were fed off in time for giving the ſame tillage as before, and the land was ſowed the 8th of February; reaped as before. The produce four quarters, ſeven buſhels, one peck per acre; a ſhorter and better ſample than any I had from later ſowing.

1787.

“ Thirty acres were ſown this year as before on turnip land, and in ridge and furrow. Began the 6th of February; ploughed between the ridges once; reaped; one ſtack has been threſhed; the reſt is equal; the produce five quarters one peck per acre; the ſample ſhort and good; and weight 14 ſtone 7lb. the ſack.

1788.

“ This year I have ſowed 43 acres in the ſame manner; began the 5th of February, and finiſhed ſoon after: the reſult you ſhall be informed of.

“ From theſe particulars it is evident, that the practice, however contrary to the common method, has ſucceeded remarkably well, nor do I ſee any well founded objection to purſuing it on the largeſt ſcale.

“ It has been ſaid, *if you feed off your turnips ſo early in the ſeaſon, what do you do for your food later?* To me it appears, that the right time to eat a crop is when it will yield the moſt food, and go the fartheſt. Turnips are often kept till they are good for nothing; and every one knows, in this county, that it is no uncommon thing to ſee them given away to have them fed off, for what the farmers call time for barley; that is, in April and even in the beginning of May. This late ſeeding inſures the loſs of two crops; the turnips are worth nothing; the land is impoveriſhed by them, and there is no chance of good barley.

"Would it not be much better for the farmer to have other reſources for his ſheep, than ſuffer ſuch certain loſs, and run ſuch great hazard? I am ſo well convinced of this, that I do not venture barley after late fed turnips, but reſerve the land for cabbages.

"But beſides this reply to the objection, I may obſerve that the practice is directly applicable to all the lands fed off by the end of January, and to all other preparations for barley, excluſive of the queſtion of late feeding; but the farmers leave their lands till the common ſeed time, giving twice the tillage that I do, to get worſe crops.

"You will obſerve that I ſow no clover or other ſeeds with barley. I think the expectation of having two crops growing on the land at once, not very well founded: indeed, ſucceſs is the worſt thing that can be looked for; as we often find in late harveſts, in which the Barley is left out ſo late for the clover to dry as to become black, and in every reſpect a bad ſample.

"It is better to ſow the ſeeds alone. But thoſe who will perſiſt in this bad management, may do it at an early ſeaſon as well as at the common one, ſeeing that all the plants ſo cultivated are indigenous, and, therefore, may be ſown at any time.

"Another advantage of ſowing early is early harveſt; from a fortnight to three weeks is thus gained: Every one knows the conſequence of this."

We perfectly agree with Mr. Young in the very juſt eulogium he beſtows upon the noble Earl, and conſider the minute attention a perſon ſo elevated in life as his lordſhip, beſtows on Agriculture, as a happy circumſtance to this country. At the ſame time we cannot help thinking that a few acres of turnips in ſpring, are of more conſequence than his lordſhip thinks them; particularly on cold backward ſoils, where herbage lies late.

To eat turnips off in ſpring, as early as poſſible, is certainly good management, as when they begin to put forward for ſeed, they exhauſt the land, and oftentimes keep ſeeding back to the injury of the Barley crop.

But with theſe diſadvantages, the value of turnips, to thoſe who have a flock of ſheep, and no graſs or other herbage to put them to, cannot be diſpenſed with; and taking one ſeaſon with another, we do not think prolonging a part of the Barley ſowing to the middle or latter end of April, a circumſtance of material conſequence, as the late ſowed Barley is ſometimes ſuperior.

The Bath ſociety papers being held in eſtimation; and as they contain a variety of information not generally known or practiſed, we can do no other than preſent our readers with the following letter to that ſociety.

"THE beſt ſoil is that which is dry and healthy, rather light than ſtiff, but yet of ſufficient tenacity and ſtrength to retain the moiſture.

"On this kind of land the grain is always the beſt bodied aad coloured, the nimbleſt in the hand, and has the thinneſt rind.

"Theſe are qualities which recommend it moſt to the maltſter. If the land is poor, it ſhould be dry and warm; and when ſo, it will often bear better corn than richer land in a cold and wet ſituation.

"In the choice of your ſeed, it is needful to obſerve, that the beſt is of a pale lively colour, and brightiſh caſt, without any deep redneſs or black tinge at the tail. If the rind be a little ſhrivelled, it is the better; for that ſlight ſhrivelling proves it to have a thin ſkin, and to have ſweated in the mow.

"The neceſſity of a change of ſeed by not ſowing two years together what grew on the ſame ſoil, is not in any part of huſbandry more evident than in the culture of this grain, which, if not frequently changed, will grow coarſer and coarſer every ſucceeding year.

"It has generally been thought that ſeed-barley would be benefited by ſteeping; but liming it has, in many inſtances, been found prejudicial.

"Sprinkling a little ſoot with the water in which it is ſteeped has been of great ſervice, as it will ſecure the ſeed from inſects.

"In a very dry ſeed-time, Barley that has been wetted for malting, and begins to ſprout, will come up ſooner, and produce as good a crop as any other.

"If you ſow after a fallow, plough three times at leaſt. At the firſt ploughing, lay your land up in ſmall ridges, and let it remain ſo during the winter, for the froſt to mellow it; the ſecond ploughing ſhould be the beginning of February.

"In March ſplit the ridges, and lay the land as flat as poſſible, at the ſame time harrowing it fine. But in ſtrong wet lands (if you have no other for Barley) lay it round, and make deep furrows to receive the water.

"I have often, continues he, taken the following method with ſucceſs: on lands tolerably manured, I ſowed clover with my Barley, which I reaped at harveſt; and fed the clover all the following winter, and from ſpring to July, when I fallowed it till the following ſpring, and then ſowed it with Barley and clover as before.

"Repeating this method every year I had very large crops, but would not recommend this practice on poor light land.

"We ſow on our lighteſt lands in April, on our moiſt lands in May; finding that thoſe lands which are the moſt ſubject to weeds produce the beſt crops when ſown late.

"The common method is to ſow the Barley-ſeed broad-caſt at two ſowings; the firſt harrowed in once; the ſecond twice; the uſual allowance from three to four buſhels per acre. But if farmers could be prevailed on to alter this practice, they would ſoon find their account in it.

"Was leſs ſeed generally ſowed the produce would be equal, and the corn leſs liable to lodge: for when corn ſtands very cloſe, the ſtalks are drawn up weak; and on that account are leſs capable of reſiſting the force of winds, or ſupporting themſelves under heavy rains.

"From our great ſucceſs in ſetting and drilling Wheat, ſome of our farmers tried theſe methods with Barley; but did not find it anſwer their expectations, except on very rich land.

"I have myſelf had 80 ſtalks on one root of barley, which all produced good and long ears, and the grain was better than any other; but the method is too extenſive for general practice.

"In poor land, ſow thin, for your crop will be worth little. Farmers who do not reaſon on the matter will be of a different opinion; but the fact is indiſputable.

"When the Barley is ſowed and harrowed in, he adviſes that the land be rolled after a ſhower of rain, to break the clods. This will cloſe the earth about the roots, which will be a great advantage to it in dry weather.

"When the Barley has been up three weeks or a month, it is a very good way to roll it again with a heavy roller, which will prevent the ſun or air from penetrating the ground to the injury of the roots.

"This rolling, before it branches out, will alſo cauſe it to tiller into a great number of ſtalks; ſo that if the plants be thin, the ground will be thereby filled, and the ſtalks ſtrengthened.

"If the blade grows too rank, as it ſometimes will in a warm wet ſpring, mowing is a much better method than feeding it down with ſheep; becauſe the ſcythe takes off only the rank tops, but the ſheep being fond of the ſweet end of the ſtalk next the root, will often bite ſo cloſe as to injure its future growth.

"By attending to what I here recommend, many of our farmers uſually get forty buſhels of barley per acre, from land of no extraordinary quality. On ſome that is rich, I have had fifty-two buſhels without manure; but I never ſow more than ten, and often only eight pecks of ſeed per acre.

"I am, &c.

"J. S."

Steeping or ſoaking of Barley has been a cuſtom recently adopted, to guard againſt the injuries and inconveniences attendant on a dry ſeed time.

To ſay it has anſwered the intended purpoſe, would be ſaying too little, as wonders have been performed, by means of ſteeping Barley; as the following Letter to the Secretary of the BATH SOCIETY, by Mr. JAMES CHAPPLE, of BODMIN, will teſtify.

ON STEEPING SEED BARLEY IN A DRY SEASON.

"MY great ſucceſs in making the following experiment, occaſions my communicating an account of it to you, for the benefit of the public, if thought worthy a place in the Bath Society's Experimental Papers.

"The laſt ſpring being remarkably dry, I ſoaked my ſeed-barley in the black water, taken from a reſervoir, which conſtantly receives the draining of my dung-heap and ſtables. As the light corn floated on the top, I ſkimmed it off, and let the reſt ſtand twenty-four hours.

"On taking it from the water, I mixed the ſeed grain with a ſufficient quantity of ſifted wood aſhes, to make it ſpread regularly, and ſowed three fields with it. I began ſowing the 16th, and finiſhed the 23d of April; the produce was ſixty buſhels per acre, of good clean Barley, without any ſmall or green corn, or weeds at harveſt; no perſon in this country had better grain.

"I ſowed alſo ſeveral other fields with the ſame ſeed dry, and without any preparation; but the crop, like thoſe of my neighbours,

bours, was very poor; not more than twenty buſhels per acre, and much mixed with green corn and weeds when harveſted. I alſo ſowed ſome of the ſeed dry on one ridge in each of my former fields, but the produce was very poor in compariſon of the other parts of the field."

The important advantages which Mr. Chapple derived from ſteeping Barley, are greatly in favour of the method, and his laying the reſult before the public, deſerves every commendation. The ſucceſs attending his experiment would appear incredible, if the teſtimony had not been ſo reſpectable and concluſive.

Mr. Chapple's land muſt have been of a ſuperior quality as ſixty buſhels on an acre, is a crop almoſt unprecedented: at all events the material difference between the ſeed which was ſteeped before it was ſowed, and that which was ſowed dry, will certainly bring the cuſtom into general practice.

BROAD EARED BARLEY AND BEAR.

Broad eared Barley is known by the grain being of broad flat make, both ſhorter and broader than the long eared Barley, and generally ſomewhat larger and heavier; this kind is beſt ſuited to ſtiff loam or clay, and ſhould be ſowed early, as it does not ripen ſo ſoon as the long eared.

It produces a ſmall quantity of ſtraw, and that rather coarſe, and not ſo fit for fodder; when kind in its nature, it makes ſtrong malt, and yields a deal of meal or flour.

Bear or Big is moſtly cultivated in Scotland and Ireland, and is ſowed in autumn, as we do wheat; it is harder in its nature, than the Barleys in general uſe in England, and inferior in quality, neither producing ſo good beer when brewed, nor yields ſo fine a ſpirit when diſtilled.

There is another grain claſſed with Barley, and called Siberian Barley; it is ſmooth in the ſkin like wheat, and of colour more reſembling rye; it weighs heavy, and of courſe yields a large quantity of meal; and is not ſuitable to any purpoſe, except for pigs and cattle, for which it is equal to our common kinds of Barley.

If the practice of cutting Barley more early than uſually is done was adopted, ſamples would be produced at market of a better colour, and the corn would have a much better advantage in caſe of a caſualty HARVEST.

SECT. V.

OATS AND THEIR CULTIVATION.

OATS are in their nature more ſuited to our climate than any other kind of grain we are acquainted with; one ſpecies of the Oat ſeems a native, as it grows ſpontaneous on cultivated land, and cannot be deſtroyed; but this is of a very bad ſort, and commonly called a rough Oat, and held in no greater eſtimation than the baſeſt weed; all thoſe in cultivation are probably exotics.

The Oat family are very numerous, and, like the human ſpecie, are black, white, and of a reddiſh or copper colour. Thoſe of the white kind, are the thin ſkined Oat, commonly called the Dutch Oat, and the Poland Oat, brought into England from Poland.

Thoſe of the Black kind, are the common Black Oat, in its nature much reſembling the Dutch Oat, (colour excepted) and the Siberian Black Oat, reſembling the Poland Oat, with the former exception; for which reaſon it will be needleſs to ſpeak of them any otherwiſe than as two ſorts, the tawny not being materially different from the Poland Oat.

The White Dutch Oat, and the common Black Oat, are alike thin in the ſkin or huſk, and produce a large kernel. White Dutch Oats are imported in large quantities for ſeed, every year, from Holland, as they degenerate by being repeatedly planted in this kingdom; and, in proceſs of time, a great many of them become grey.

The common Black Oat we believe is ſeldom introduced from any foreign climate, neither is it cultivated ſo much as it was ſome years paſt. One objection to the Black Oat is, thoſe corns which drop on the land at harveſt, growing again the next year with Wheat or Barley, and being mixed with them has a very unſightly appearance; otherwiſe they are in every reſpect as uſeful and prolific as any Oat that grows.

The Poland Oat, and the Black Siberian, are much thicker in the ſkin or huſk, than thoſe we have juſt mentioned, and the kernel is not larger. This being a material diſadvantage, we ſhall let them paſs, and recommend for general cultivation, the White Dutch Oat, which for horſes, or to make oatmeal, ranks foremoſt of thoſe we are at preſent acquainted with.

Oats accommodate themſelves to any kind of ſoil, and are a more certain crop than any other kind of grain; but, like all others, they never return much profit without good management; and the perſon who expects a good crop of Oats, becauſe his land is not in condition to produce any thing elſe, will be very apt to deceive himſelf. Although, in the South part of England, Oats are not uſed for any other purpoſe except for horſes, and a ſmall quantity for grotes and oatmeal; in the northern parts of the kingdom they are in great and general eſtimation, as food for the human ſpecies, which, by the temperate mildneſs of their nature, they are well adapted for; and if we judge of the quality of the the food by the health and ſtrength of thoſe who eat it, where can we find a race of beings more healthy and ſtrong than the inhabitants of Scotland, and the north of England, where the product of the Oat makes the chief part of the food of the middle and lower claſs of the people.

The ſeed uſually allowed for an acre is four buſhels, but ſometimes more are ſowed; but if it is good, and to be depended upon, and the land clean and in good tilth, four buſhels are ſufficient. Changing the ſeed from a different kind of ſoil, is by no means to be neglected.

Formerly the cuſtom of ſowing Oats was in March and April, and ſometimes after the barley ſeeding; but that cuſtom is now altered, and Oats are generally ſowed the beginning of February, or as ſoon as the ſeaſon will permit, and are moſtly the grain which brings in harveſt.

We have ſeen excellent Oats ſowed in autumn, which were ripe a month before any other corn; but it is not a cuſtom to be recommended to general practice, as a ſevere winter will be very likely to deſtroy them.

When oats are ſowed early, it is not requiſite to ſoak or ſteep the ſeed, but on the contrary dangerous; but ſhould the ſeeding, from circumſtances, be deferred till the latter end of April, they who ſteep them all night in water, before they diſtribute them on the earth, will, taking one ſeaſon with another, find it much to their advantage.

Oats well managed and ſowed in proper ſeaſon, are a productive and profitable crop: and as the following experimental information, publiſhed in the Bath ſociety's papers, is curious, and to the purpoſe, we preſent it to our readers.

ON BLACK OATS.

“ THE preceding year it had carried potatoes, and received one ploughing for a winter fallow.

“ In February laſt another ploughing was given, and on the 27th and 28th of the ſame month four Wincheſter buſhels per acre of Black Oats were ſown; this was earlier by about a month, than oats are generally ſown in our pariſh, and I did it with a view to aſcertain the effects of early ſowing; when the Oats were ripe, I cauſed exactly half an acre to be cut with the ſickle and ſheaved; theſe were threſhed out, the produce was $49\frac{1}{8}$ Wincheſter buſhels, a quantity moſt amazing in theſe parts. The ſucceſs of the crop, I impute partly to early ſowing and partly to good deep tillage; and, I believe, the half acre was a fair average of the whole piece.

Expences of an Acre.

	£.	s.	d.
Rent	2	0	0
Two ploughings, at 5s.	0	10	0
Cutting	0	3	0
Harveſting	0	5	0
Four buſhels of ſeed, at 2s. 6d.	0	10	0
Sowing and harrowing	0	3	0
	£. 3	11	0
Produce.			
$98\frac{1}{4}$ buſhels of Oats, at 2s.	9	16	6
Deduct expences	3	11	0
Profit	£. 6	5	6

“ The ſtraw may be valued in lieu of threſhing, conveying to market, &c. but is worth abundantly more than what would defray thoſe expences.

“ I am, Sir,

“ Your obedient ſervant,

“ NEHEMIAH BARTLEY.”

As fodder, the ſtraw of Oats, is reckoned ſweeter and of more value for cattle than the ſtraw of any other kind of grain; particularly if the crop was not very large and ſtrong. When Oats are a very plentiful crop and grow high, it is good huſbandry to reap and bind them in ſheaves, as it is cuſtomary with wheat; by this means they are not ſo liable to be loſt on the land, as no grain ſo eaſily beats out as Oats, and although the expence is greater, the ſaving from waſte amply repays it. If the crop is not large, and they do not grow high in the ſtraw, the uſual cuſtom of mowing them with the ſcythe is to be preferred.

Oats are certainly a grain not ſo exhauſting in their nature as wheat, barley, or rye, and better ſuited to the great variety of ſoils with which this country abounds; neither does it require ſo much care to depoſite them in the earth, as we have frequently ſeen in a dry ſpring Oats ſowed upon a clay ſoil freſh broke up, where apparently they could not be ſufficiently buried in the earth to cauſe them to vegetate, as the heavieſt drag or harrow, made little impreſſion on the ſoil, and yet this management has been productive of an excellent crop. We do not mean to infer from this, that it is immaterial whether they are tilled in a proper manner or not, but only to ſhew the probable advantages which may be expected, provided circumſtances are not ſo favourable as could be wiſhed.

As a proof of the poſſible produce of a crop of Oats, we ſhould not think ourſelves juſtified if we did not lay before the public an extract from Mr. Young's Annals of Agriculture, Vol. 8. p. 104. and with which we conclude the article; and truſt the reader will ſay, we conclude well.

AN EXTRAORDINARY CROP OF OATS,

“ Reaped laſt harveſt by the Rev. Mr. CARNE, Vicar of
“ ABBERFORD, in Yorkſhire. The land contained exactly 3
“ acres, 1 rood, 10 perches. Before it was under the plough it
“ produced nothing but ruſhes, being a wet ſwampy ſoil.
“ Mr. CARNE drained it, and ſowed it with Oats, and reaped
“ 314 buſhels. He ſold the Oats for 36l. 13s. 6d. and the
“ Straw for 12l. 6s. 2d. amounting to 48l. 19s. 8d.”

Let it be remarked, there was neither drilling nor horſe-hoeing in producing this crop.

SECT. VI.

BEANS, PEAS, AND THEIR CULTIVATION.

BEANS are of various kinds, but thoſe in common cultivation for agricultural purpoſes are not very numerous, the large common horſe Bean of a longiſh ſhape is the moſt in general uſe; and one of a much ſmaller kind approaching in ſhape and ſize to that of a pea, but rather long than round, this in ſome countries is called the Berkſhire Bean, and in others the tick Bean.

They are doubtleſs very prolific in their nature, branching a number of ſtems from the ſame root, each of which is frequently armed with pods from top to bottom; curious perſons have been induced to number the product of a ſingle Bean, and have diſcovered three hundred and upwards ariſe from one.

This brings to our recollection a circumſtance, apropos, which happened at Bourton on the Hill, in the county of Glocester. A perſon by profeſſion a taylor, walking in the field, accidentally picked up a Bean-ſtalk, and on a minute inveſtigation diſcovered that its contents of fair marketable Beans amounted to upwards of eighty; revolving this demonſtrative truth in his mind, the obvious profits attending on the buſineſs of a farmer wanted no further proof; and having a ſmall farm of his own in the pariſh, which he had acquired by induſtriouſly purſuing his trade, gave his tenant notice to quit, and immediately commenced farmer, converting his *ſhears* into plough ſhares, and his *needles* into weeding hooks. Thus having quitted the ſhopboard, his next object was, to farm out of the beaten track of obſtinate farmers; of courſe, being a man of letters, he purchaſed books, and became an admirer and diſciple of the celebrated Jethero Tull. Drilling and horſe-hoeing were the only profitable methods for an enlightened farmer to purſue; if one Bean produced an hundred, what occaſion could there be to throw ſeed away in the common method? Like a true experimentaliſt, this ſhred of a farmer, went drilling on, condemning and deſpiſing every body who was not as wiſe as himſelf; till at length he diſcovered that the ſyſtem, which he followed, was deſigned for experiment only and that thoſe who were its advocates; never thought of getting money; it was having too much that made them diſcontented and whimſical.

To alter his plan it was too late, for his eſtate was mortgaged, and his credit became bad: there was no reſource, but to return to the deſerted *bodkin and thimble*; but, alas! his eyes were waxed dim; he could not ſee to thread the needle; hard labour had made his hands ſhake; he pricked his fingers as often as the cloth.

To conclude this detail, this unfortunate and induſtrious man from this period lived and died a pauper.

We hope to be excuſed for this ſhort digreſſion, which contains nothing but the plain truth; our readers may comment upon it as they pleaſe.

Beans are reckoned a meliorating rather than an exhauſting crop, and are beſt to plant on wheat or barley ſtubble; where the ſoil is of a mellow, friable nature, and the roundneſs or convexity of ridges not too great. Drilling Beans may anſwer the purpoſe very well; but on ſtiff clay, or loam, drilling will ſcarcely be found practicable, except the land is in excellent tillage and the ſeaſon very favourable. Dibbling or ſetting may be practiced almoſt any ſeaſon, and on any kind of ſoil; the diſtance between the rows about twelve inches, and between each Bean in the row two inches; it is an error to drop more than one Bean into each hole you make with the ſetting ſtick or dibble: Beans planted in this manner ſhould be well hoed twice or thrice in the courſe of their growing, minding each time to hoe before the weeds become high or ſtrong, as cutting them in their infant ſtate bids faireſt to deſtroy them.

Mr. Young's accurate calculations and obſervations being held in high eſtimation, we tranſcribe the following from his Annals, Vol. 7. p. 204.

The ſoil is a ſandy loam, with a very ſmall portion of calcareous earth: this for 8 inches deep, and under it a wet clay marle. The deſcent gently to the north. It was worth about 11s. an acre. In the year 1784, I fed it. In November of that year, manured it with 220 ſingle horſe loads of farm-yard compoſt, made in the preceding winter. In 1785, it was mown. March 17, 1786, ploughed it. April the 3d, dibbled it with horſe Beans; three lands, containing 3 roods and 31 poles, one row on every furrow, (9 inches wide) and the reſt of the field, containing 3 acres, 1 rood, and 8 poles on every other furrow. The intention of the experiment was to diſcover which of theſe methods was beſt; ſome trials on drilling Beans in tilth land at different diſtances have been publiſhed, but I know of none of doing the ſame thing on a lay. The ſeed was put in 4 inches from Bean to Bean in the wide rows, and 5 in the narrow ones. My orders were 2 inches in the former caſe, and 4 in the latter, which would have made quantity of ſeed the ſame in both; bnt there were uſed on the piece of narrow rows, at the rate of 8 becks an acre, and for the wide ones, 7 per acre. The expence of dibbling the latter 3s. 3d. and of the former 5s. per acre. The rows at 18 inches were horſe-hoed with a ſhim three times and hand-hoed thrice. The others were hand-hoed twice and looked over ſlightly a third time. The expence of the whole in labour 2l. 1s. 8d. or 10s. an acre. In dividing this ſum, the narrow rows were at the rate of 5s. the firſt hoeing; 4s. 6d. the ſecond; and 2s. 6d. the third, in all 12s. The hand-hoeings of the wide ones were 3s. 2s. 6d. and 2s. 6d. or 8s. in the whole; to which add, for three horſe-hoeings, including man, boy, and horſe, 3s. 3d. a day, or, at four acres a day, 10s. an acre; in all, for the wide rows, 8s. 10d. At harveſt cutting, the narrow rows was 6s. an acre, the wide ones 5s. All other expences the ſame to both. Laid and threſhed them ſeparate; produce of the 3 roods 31 poles, narrow rows, 7 coomb 2 buſhels; of the 3 acres, 1 rood, 8 poles, wide rows, 16 coomb 2 buſhels. The proportions are, pretty exactly, 8 coomb per acre, narrow rows; 5 coomb per acre, wide ones. Accounts per acre.

N. B. A coomb is 44 buſhels.

OBSERVATIONS,

The firſt remark I have to make, is on the great ſuperiority of the cloſe planting; this has reference chiefly to the poverty of this cold and exhauſted ſoil. In proportion to the weakneſs of land ſhould be the quantity of ſeed; and thoſe who plant upon better ſoils may ſet them thinner; upon very rich ones, every other furrow, would, probably, do better than on every furrow. But the circumſtance of its being on a lay is not to be forgotten: tilth land is far more ſubject to weeds, in which caſe the introduction of the horſe-hoe may more than make amends for the deficiency in number of plants: it has hardly fair play on a lay, for the moulds are not in quantity for it to work in.

The ſuperiority of every furrow is very great indeed: the profit in one caſe is ample, amounting to near three rents, which is as much and generally more than is to be expected from wheat in common culture: but, in the wide ſows, the advantage is, on compariſon, very little.

Intereſting obſervations might be made even on the ſmalleſt product, in relation to fallowing; but I forbear, as the what muſt be reaped, with which the field is ſown, and brought to an account before that compariſon can be fully aſcertained.

I muſt beg the reader will have candour enough to pronounce no condemnation on the management of this crop, from the ſmallneſs of the produce: the land is naturally poor, wet, and cold: I took it at the expiration of a leaſe, during which, the tenant had done much to exhauſt, and nothing to repleniſh it. It was flat, and without drains: the dunging, it is true, did ſomething; but nothing on compariſon with the effect it would have had, had it been laid dry. The Beans were unavoidably planted too late; and the harveſt was unfortunate. There wants little information of the culture on rich, deep, friable loams: but to know that they may be depended upon on poor wet loams of 10s. or 12s. an acre, is a point not at all aſcertained, and of much importance to various queſtions of rural œconomy.

One other circumſtance ſhould be mentioned, that the ſtraw, notwithſtanding the unfavourableneſs of the harveſt, proved of great uſe to my lean cattle. They were tied up in ſtandings, in Mr. Bakewell's method, and from having good barley and oat ſtraw, were put to that of Bean, and nothing elſe to depend on, without at all feeling off in their looks; but they had it given them in larger quantities. The ſtraw well harveſted is known in various parts to be very valuable, eſpecially for horſes. I found it ſo for cows and young cattle. The price charged in this experiment is what it paid, reckoning the cows at 9d. and the young cattle, at 6d. per week. I need not obſerve, that the object of dung is more conſiderable than this.

This practice and the obſervations thereon, ſhew Mr. Young a *man of buſineſs* an appellation, which we hope he does not think derogatory to that of a gentleman.

As novelty is generally ſought after with eagerneſs, particularly when it is blended with ſomething of the wonderful, we preſume the following letter by Mr. JOHN BULTS, of Kingſtone, near Taunton, to the Secretary of the Bath Society, will be acceptable.

ACCOUNT OF A CROP OF BEANS AND TURNIPS IN ALTERNATE ROWS.

"IN reply to your enquiries relative to my drilled crop of Beans, with the turnips in the intervals, I ſend you the following particulars:

"The field meaſures ſix ſtatute acres and a quarter, and is a good clayey ſoil.

"The Beans were planted in drills near two feet a part on two ploughings, and horſe-hoed three times, the turnips being ſowed in the intervals at the third or laſt hoeing.

"There has been no kind of manure or dreſſing laid on the land for ſix crops paſt, nor is there any need of it; as I find by experience that drilling and horſe-hoeing anſwer the end fully. The crop of Beans was near three quarters per acre.

"The weight of turnips was thirty ſeven tons five hundred weight, as meaſured and weighed by Mr. Pavier, and Mr. Headford: theſe turnips are now feeding off. Thirty one head of horned cattle, ſixty ſeven ſheep, and twenty ſix pigs, have been maintained by them for a month paſt; and what remains will keep them at leaſt a month longer. The whole expence of drawing and carting them into an adjacent field for the cattle, is between ſix and ſeven ſhillings per acre.

"I am, &c.

"JOHN BULT."

Mr. Bult's ſurpriſing ſucceſs, is enough to rouſe every farmer who regards his own intereſt, to the horſe-hoeing ſyſtem; thoſe who feel themſelves diſpoſed to make the experiment, we wiſh them ſucceſs.

This account by Mr. Bult is further confirmed by two letters on the ſame ſubject, by Mr. Thomas Pavier, of Weſt-Monckton. Were we to form any conjecture on this buſineſs, it would be that Mr. Bult's land was of a ſuperior quality; but admitting that to be the caſe, he has no reaſon to repent his management.

As the broad Windſor Beans, are ſometimes planted for agricultural purpoſes, we will mention a few circumſtances reſpecting their cultivation. They ſhould be planted on ſtrong rich land about the beginning of April, if the weather permit, and ſet or dibbled in rows of eighteen or twenty inches aſunder, and four inches diſtance from Bean to Bean in the rows, and ſhould be hoed twice or three times. To make them pod the better, and to facilitate their ripening, it is good management if the crop is luxuriant and ſtrong to cut about two inches off the top of each Bean (with a reaping hook, or ſome ſuch inſtrument) juſt at the time the bloſſom begins to fall; this labour is quickly performed, and gives the ſun admiſſion, and keeps the ſap down to nouriſh the Beans, which is eſſentially neceſſary, as the principal objection to their cultivation for ſeed is the lateneſs of their ripening.

Theſe Beans, likewiſe all others of the Bean kind, when the crop is large and good, ſhould be reaped as ſoon as the ſtraw begins to turn black; the beſt method of managing Beans is what they call in the inland counties, pucking them; that is, ſetting them up in ſingle ſheaves extended wide at the bottom, and tied together at the top, in a conic ſhape, reſembling a ſugar loaf; this, in the countries where it is practiced, is done for four or five ſhillings per acre, and we have known them ſtand in the field till the middle of November, and when thraſhed there has not been a black or decayed Bean in the ſample.

PEAS.

There are ſeveral kinds of Peas in cultivation, of various colours and ſhapes, the grey Peas moſt commonly ſowed in fields are the early Charlton and the common late ripe pea; theſe do not flouriſh ſo well in a clayey ſoil; but on all ſoils, which bear good corn of other kinds you may naturally expect good grey Peas, they ſhould be planted as early as the ſeaſon will permit, are generally ſowed under furrow or ploughed in; but the only proper management is to drill them if circumſtances will admit, and if not, ſet or dibble them. White and blue Peas ſhould be planted on a good friable loam, or on a ſandy or gravelly loam; in March, or the beginning of April, ſome land will bear them to boil tender, and other kind of land will not; there is no juſt and infallable rule by which the proper ſoil to produce them good boilers can be aſcertained, therefore experience alone muſt determine. As Peas are planted for a meliorating crop, they ſhould be never ſowed broad caſt, as by that means hoeing is prevented, which is of great ſervice to the crop of Peas, and doubly ſo to the land for the ſucceeding tillage. There is a large egg ſhaped Pea lately introduced, called the American Pea; and if planted on warm rich land, anſwers extremely well; but if land is not of that deſcription, we by no means would recommend its cultivation out of the garden, but for culinary purpoſes they are ſuperior to any kind that are known in this country.

Peas of all kinds ſhould be cut before they are too ripe, otherwiſe the pods will open, and a great loſs will be ſuſtained by their ſhedding on the ground, particularly ſhould the weather be aukward. Mowing peas with a ſcythe may with juſtice be called a ſlovenly practice, whether they were planted broad caſt, or in rows by drilling or ſetting. The beſt method to cut them is with a hook, like a reaping hook fixed to a ſtick 3 feet long or upwards, and generally called a ſtaff-hook; although ſome prefer a common reaping hook to cut them with, and a hooked ſtick or an old ſickle in the other hand, which is very uſeful in parting them, in order to place them in ſmall cocks or heaps. Practice, which makes all things familiar, makes ſome prefer one way and ſome the other; in either method care ſhould be taken not to make the heaps too large; in fact, you cannot err by making them too ſmall

SECT. VII.

VETCHES OR TARES, RYE, BUCKWHEAT, LENTILLS OR TILL, AND THEIR CULTIVATION.

THE kinds of Vetches (or perhaps, as they are more generally called, Tares) which are cultivated in this kingdom, are the winter Vetch, which is of a ſmall kind and ſowed in autumn, and the ſpring Vetch ſowed in ſpring; theſe are very ſeldom uſed for any other purpoſe, except as green food for cattle of all kinds.

AGRICULTURE.

Sometimes they are mowed and given to horſes in the ſtable, or to horned cattle in yards, and ſometimes eat off the land by ſheep, or young cattle, in the manner of turnips. As Vetches, when they are ſowed on warm dry land in autumn, or the latter end of ſummer, produce early ſpring feed; their cultivation is particularly neceſſary where graſs lies backward, to ſupply the ſpace between the finiſhing of the turnip crop and the time when natural graſs is in condition to have cattle turned into it. This is an acquiſition of material conſequence to every farmer, as green food is always at that time much wanted, for ſheep in particular, for breaking or turning cattle into paſture early in ſpring before graſs has attained any forwardneſs, is keeping herbage low all the ſummer, by nipping the tender plant before it has arrived at any degree of ſtrength. Winter Vetches ſhould be ſowed as ſoon as poſſible after the preceding crop is cleared off the ground, that they may acquire ſufficient ſtrength before the ſeverities of winter appear, which will alſo render them forward in the ſpring.

Spring Vetches are ſowed any time in ſpring to follow thoſe of the winter kind, and may, if requiſite, be ſowed from time to time, to procure a ſucceſſion of crops during the ſummer.

After early Vetches are ſpent, there is a very good opportunity of giving land a partial ſummer fallow. We have known buckwheat ſowed in May, or the beginning of June, after winter Vetches, and ploughed in to manure the land for a crop of wheat or ſpring corn; and if land is clean from weeds it is certainly excellent management, particularly on land of a light texture.

The Rev. Mr. LAURENTS, of Bury St. Edmunds, an intelligent gentleman, who correſponds with Mr. Young, has proved, from ſeveral demonſtrative experiments, that the winter and ſpring vetch are by no means calculated as ſubſtitutes for each other, although it is a prevailing opinion that both will anſwer the ſame purpoſe: theſe experiments are ſo clear, that we would wiſh to caution the huſbandman in this particular.

The wild Vetch, or Tare, has been lately cultivated in a particular ſucceſsful manner by the Rev. Mr. Swayne; and if the ſeeds can be preſerved bids fair to become an article of importance in Agriculture.

As we cannot do juſtice to this gentleman's curious and uſeful experiment if we abridge or alter his letter, we beg leave to lay it before the public in his own words, as communicated to the Bath Society.

ON THE CULTURE OF THE BUSH VETCH.

By the Rev. Mr. Swayne, of Pucklechurch.

The plant which the ſtatement reſpects is, the Buſh Vetch, or botannically, according to Linnæus, (Vicia Sepium.) It is not only a perennial, but an ever-green: it ſhoots the ear beſt in the ſpring of any plant eaten by cattle with which I am acquainted, vegetates late in autumn, and continues green through the winter; add to this, cattle are remarkably fond of it.

"IN the autumn of the year 1782, I collected a quantity of theſe ſeeds from the hedges, &c. March 15th, 1783, I ſowed them in drills in a plat of ground in my kitchen garden, which meaſured exactly five yards ſquare; they were ſown in eight drills, as thick in the drills as I would have ſown peas. They came up very thin and irregular; in ſome places there was more than a foot vacancy between plant and plant. This I was much ſurpriſed at, as the ſeed had been carefully preſerved during the winter, and I could not, from their appearance at the time of ſowing, ſuſpect them to be in the leaſt defective. The plants grew very ſparingly till towards the autumn, but before winter they made a tolerable appearance.

"This plat is in the moſt expoſed part of my garden; the ſoil a blackiſh loam, rather ſtiff; it had been planted with potatoes the year before, for which I believe it was dunged, but am not certain; the two preceding years it was uſed as a nurſery for Lombardy poplars.

"Early in July 1783, I collected ſome more of theſe ſeeds from the hedges, tied them up in a paper, and put them in a drawer of my bureau. Upon opening the paper in September, I obſerved a vaſt number of dead flies in it, and as many of the ſeeds with a ſmall hole in each. The number of the flies was 280. The whole number of the ſeeds 1080. Theſe flies, upon examination, proved to be a ſmall ſpecies of ichneumon. This puzzled me not a little, as I had learnt that theſe inſects were termed a race of cannibals, from their larvæ or caterpillars always feeding on other inſects. Upon which I opened many of the other ſeeds that had no holes in them, and in ſeveral of theſe diſcovered another inſect, alive, and in different ſtates of its growth. This proved to be the *bruchus piſi* of Linnæus, a near relation of the weevil [*curculio*] and the attelabus. From hence I ſurmiſed, that at the time when the buſh-vetch bloſſoms the female bruchus lays her egg within the bloſſom, and the ichneumon immediately after depoſits her egg in the ſame place.

"After the froſts were over, I was much pleaſed to obſerve, that ſcarce a plant of my vetches had been killed by them, and their verdure very little injured. In April 1784, they had entirely filled up the ground, and were beginning to flower; at this time I found, as I expected, numbers of the bruchi intruding themſelves into the bloſſoms, before they were ſcarcely open, and the attendant ichneumones ready to follow them. I uſed every method I could think of to chaſe away theſe inſects from my crop, by ſtrewing ſoot over, kindling ſmoaky fires around, &c. but all to no purpoſe.

"In the beginning of May the Vetches were in full bloſſom, and it was amazing to ſee what a croud of inſects were ſwarming about them. At that time I intended to preſerve the Vetches for ſeed; but ſome time after, obſerving that they were beginning to rot from their over-luxuriance, I cut them, without taking any particular account of the produce. They were cut twice afterwards during the ſummer. Having remarked in general that the produce of theſe cuttings was very great, I was determined this year to keep a particular account,

"Accordingly, March 16, 1785, I began to cut the Vetches for the firſt time this ſeaſon. This cutting weighed green 16℔. I did not dry any part of it, but muſt ſuppoſe, that if dried, it would have weighed at leaſt one-fourth, as it was not near ſo ſucculent as any of the after-cuttings.

"May 17th, they were cut a ſecond time, in full bloſſom, and weighed 130 pounds,—36℔. of the green fodder weighed when dry ſix pounds.

"July 21ſt, they were cut a third time, and weighed 62℔.—33½ ℔. green weighed 8℔. dry.

"Sep. 30th, they were cut the fourth time, and weighed green 72½℔.—15lb. green weighed 2½℔. dry.

"The whole plat then of twenty-five ſquare yards produced,

		℔.		℔.	
1ſt	cutting	16	green ſuppoſed	4	dry
2d	ditto	130	ditto, would have weighed	21½	dry
3d	ditto	62	ditto, would have weighed	14	dry
4th	ditto	76½	ditto, would have weighed	12½	dry
	Total	284½	green	52	dry

"An acre therefore, (reckoning 4840 ſquare yards to the acre) in the ſame circumſtances, would have produced the total amount of

Tons.	cwt.	qrs.	℔.	
24	11	3	3	green
4	9	3	15	dry fodder.

"N. B. You are to recollect, that at the time the firſt cutting was made, there was ſcarce a green blade of graſs to be ſeen; and that the ſeaſon, till after the third cutting, was as unfavourable to vegetation as perhaps any in the memory of man.

"Your obliged humble ſervant,

PUCKLECHURCH,
OCTOBER 13, 1785.

G. SWAYNE."

As every perſon converſant in Agricultural concerns muſt have ſeen this plant in its wild ſtate, we can only wiſh to impreſs the probable idea of its promiſing utility on the minds of thoſe who endeavour to promote the art, not doubting but their labours will be crowned with ſucceſs.—For the repreſentation of the Wild Vetch, or Vicia Sepium, we refer our readers to the Plate of BRITISH GRASS.

RYE.

Rye was formerly ranked next to wheat as bread corn, but its reputation as food for the human ſpecies has been on the decline for many years, although in ſome places a ſmall quantity continues to be mixed with the wheat: this gives bread a diſagreeable ſweetneſs, and, to thoſe who are not accuſtomed to eat it, is productive of pains in the bowels, and other unpleaſant ſymptoms. It is adapted to a ſandy ſoil, not kind for any other ſort of grain, which may be the cauſe of preſerving the ſhare of repute it continues to hold as grain.

Rye ſown upon ſtubbles in autumn produces very early ſpring feed, for which purpoſe it is very uſeful.

For ſheep, ewes and lambs in particular, it is of infinite ſervice, as it vegetates earlier in the ſpring than any other kind of feed; this was the motive which induced us to range it with ſpring feed. It is for want of providing ſpring food for cattle, that people are obliged to have their ewes yean late, and without which they cannot ſupport their lambs, ſhould they come earlier; and if that is the caſe, without rye or ſome other early feed, they are under the neceſſity of eating the grounds which are intended to be mowed for hay, till perhaps the middle of May.

If a dry ſeaſon follows, theſe grounds are burned up, and the expected produce of hay wholly, or in a great meaſure deſtroyed: this might frequently be prevenſed by ſowing rye, and eating it off early, and then plough and manage as neceſſity or convenience permits for turnips.

Rye is a very exhauſting crop, if harveſted; but not ſo if it does not ſtand the ſummer.

BUCK WHEAT,

Is a native of the Eaſt, and uſed for making of bread, in the country from whence it was imported into this kingdom; but with us it gives place as food for humanity to wheats of a much ſuperior quality.

Buck Wheat will grow on a very barren ſoil, which requires very little previous preparation, and ſhould not be ſowed till all other ſpring feeding is over.

"Buck Wheat is only proper to ſow on lands of low value, and, as a Norfolk gentleman obſerves, can never anſwer on deep rich land worth a guinea per acre, as on ſuch land it produces too much ſtraw. Like all other full running crops it prevents the growth of weeds, and in Suffolk is ſown with graſs ſeeds for the purpoſe of laying down land;" but we can by no means ſubſcribe to a doctrine of that kind, as what prevents the growth of weeds will of courſe prevent the growth of tender graſſes.

The principal advantage of Buck Wheat in Agriculture is, undoubtedly, as manure on light lands, which are aukwardly ſituate for manures of other kinds: ſowing Buck Wheat after rye or winter vetches, about the latter end of May, ſeems a very rational and improving ſyſtem on poor land.

E. HOLMES, Eſq. of Scorton in Yorkſhire, obſerves, in his correſpondence with Mr. YOUNG, that turnips are to be preferred: we agree with him that turnips, in every reſpect where profit is conſidered, would be ſuperior; but on poor land, which has been run too hard and exhauſted, and has alſo been frequently ſowed with turnips, there is more difficulty to raiſe a tolerable crop of them than perhaps Mr. HOLMES is aware of.

Moſt farmers who have been uſed to the turnip cultivation are well convinced they are not raiſed on land, which has growed them ſeveral times, without an expenſive dreſſing of good manure, even on good loamy rich ſoil.

Buck Wheat being adapted to light land, we make no heſitation in recommending it as excellent management as above directed, and greatly before turnips on a poor light ſoil.

LENTIL, OR TILL.

Lentils are of the pulſe kind, ſomething reſembling the wild or buſh vetch. They are cultivated after the ſame manner as the ſpring vetch, and to the ſame purpoſe; but in ſome reſpects are preferable, as they will grow on poor braſhy land, ſuch as vetches will not.

Lentils are excellent as green fodder, and for hay to make horſes fat, ſuperior to every other kind: when deſigned for hay they ſhould be cut juſt after the pod or kids are formed.

SECT. VIII.

CLOVER, RYE GRASS, AND TREFOIL.

THE kinds of Clover are, the Broad Clover and the White Bloſſomed Clover, both of them of Dutch extraction, at leaſt the Hollanders taught us their cultivation, and ſupplied us firſt with ſeed, which they have continued to do annually to the preſent day.

Broad Clover is in general uſe throughout this kingdom, on land that will bear it. Should there be an individual who refuſes to ſow it, becauſe his grand-father, or father, did not, we can only wiſh his ſon or ſucceſſor may deviate from the path his predeceſſor ſo obſtinately walked in.

When land is ſowed with any kind of artificial graſs to continue one year only, Broad Clover is always fixed upon, and certainly for that purpoſe is ſuperior to all others, as it produces a plentiful crop, and is excellent as herbage, green fodder, or for hay.

Clover is better adapted to all kinds of clayey, ſtrong ſoils, than any other kind of graſs, and is very frequently, and with great propriety, ſowed among wheat on ſtrong land in the ſpring.

Land that has been repeatedly planted with Clover becomes ſatiated, or tired, particularly if it is mowed twice the ſame ſummer, or let ſtand for ſeed: when either of theſe methods are practiſed, a more exhauſting crop than Clover cannot be cultivated, nor any more profitable if attended with good luck in harveſt.

When Clover is cut for hay it ſhould be at the time the bloſſom begins to put forth, which moſtly happens the end of May, or the beginning of June: the earlier it is cut the firſt time the more luxuriant and quick will the ſhoots put forward for the next crop, and the leſs will the land be exhauſted.

White Dutch Clover is not ſo thrifty and ſtrong in its nature as Broad Clover, neither is it ſo well adapted to ſtrong land; but as a mixture with other ſeeds in laying down land for three or four years, or longer, it is extremely uſeful, as the herbage is remarkably ſweet, and its growth has more permanence. This is better ſuited to light ſandy, or gravelly loams, than Broad Clover, but ſeldom produces ſo large a crop.

RYE GRASS.

This valuable plant ſeems to have loſt ſome of its reputation amongſt the experimental gentlemen of the preſent day. Mr. Young, in particular, bears it no kind of good will: if he cultivated a large track of light loamy land, we have not a doubt but he would mix one or two buſhels of Rye Graſs with four pounds of white clover and ſix of trefoil, in laying it down for two or three years, as light lands and braſhy loams require more reſt than one year.

For lands which are tillage and paſture alternately, no artificial graſs is equal to Rye Graſs: its early appearance in ſpring, and its kind flouriſhing ſtate on land that is tired with, or not natural for, clover, will ſecure Rye Graſs a reſpectable name among artificial graſſes.

TREFOIL.

Trefoil, by ſome called Hop-Clover, is ſweet herbage for cattle, and excellent to thicken rye graſs and clover on light lands: it makes excellent hay, and on a friable loam, which ſuits it, will grow to a good crop alone. The ſeeds are incloſed in huſk, like a thoſe of ſaintfoin, and are generally ſowed as they come from the flail, and although the kernel is ſometimes ſeparated from the huſk, and is what is called milled ſeed, the method is by no means adviſeable, the growth being not ſo certain.

It may not be amiſs to remark, that a frequent change of graſſes is almoſt as neceſſary as to vary crops of corn.

SECT. IX.

SAINTFOIN AND LUCERNE.

SAINTFOIN, in ſome countries called Cinquefoil, is ſaid to have been introduced into this kingdom as early as the reign of Richard II. who brought the ſeeds with him from Paleſtine on his return from the Holy Wars, and is in that account called Saintfoint. It is a plant of great and important utility in Agriculture, and the more ſo as it flouriſhes beſt on poor rocky land, where no other cultivated graſſes will; this is certainly a very material advantage, and, what is further extraordinary, the cultivators of Saintfoin deem poor light land in the beſt ſituation to be planted Saintfoin, when it becomes ſo foul with couch graſs, and ſo exhauſted by being over-cropped, that it will produce nothing elſe. This doctrine is really ſurpriſing, but we have frequently ſeen excellent Saintfoin grow on land exactly in the condition of that we have juſt deſcribed; whether it would have been better if the land had been clean and in good condition we know not, but the proprietor aſſerted that he was well ſatisfied with his management.

Saintfoin is ſometimes ſowed alone, always in ſpring about the time of barley ſowing, after the land has had two or three winter ploughings; but the beſt and moſt common method is to ſow it with oats or barley, and not to ſuffer any cattle to feed it the next winter or ſummer following, nor yet to mow it the firſt ſummer; but let the ſeed drop on the land, which will greatly increaſe the plant. It is deemed good management to mow Saintfoin for hay every year, and ſome perſons are ſo particular that they never ſuffer a ſheep to feed it: we do not apprehend ſheep do a material injury to Saintfoin, if they are kept from it in autumn and all the winter; indeed, it is neceſſary it ſhould be kept free from cattle during the winter.

Saintfoin may be ſowed after the ſpring corn is up, as it requires a very ſlight harrowing to bury it ſufficiently, it being natural to ſtrike root. Three buſhels and an half, or four buſhels, are ſufficient to plant an acre.

A great fault reſpecting Saintfoin hay, is permitting it to grow too long before it is cut; the cuſtom being not to cut it till it is in full bloſſom; whereas if it was mowed juſt at its coming into bloſſom, the hay would be greatly ſuperior in quality, the leaves would not beat off in making, and the ſecond crop, or aftermath, would grow much ſtronger.

There is very little nouriſhment in Saintfoin hay which has been over-grown, and when it is cut with its juices in perfection, there is not any hay equal to it in goodneſs for all kinds of cattle.

The experimentaliſts recommend the drill and horſe-hoeing ſyſtem with Saintfoin: this may anſwer in a garden, or on a ſmall ſcale for the ſupport of a horſe and cow, but to keep good land in ſuch an expenſive courſe of tillage, to produce a crop, which will grow without trouble or expence on a ſoil which will ſcarcely grow any thing elſe, muſt be extreme folly.

Saintfoin ſtrikes its root very deep, particularly on a hollow rocky land, which is the beſt adapted for its culture, and will continue in perfection from twelve to twenty years; when the land is brought into tillage again, the beſt method is to pare and burn it, and plant turnips, or wheat.

Let it be noticed, that when a crop of Saintfoin has ſtood its time, and the land is again converted to tillage, Saintfoin will not grow kind a ſecond time without a long interval.

LUCERNE.

Lucerne is the *Herba Medica* of the ancients: the high eſteem they held it in appears by the extraordinary attention they beſtowed on its culture. Its roots are very large: thoſe which are above the ſurface are clothed with bark like a tree. From this, and by its ſtalk ſpringing juſt below the place where they were cut off, and the hardneſs of the ſtalks when they ſtand too long without cutting, it ſeems that Lucerne is of a nature nearly approaching to that of a ſhrub. As green fodder it is excellent for all ſorts of cattle, and as hay it is eſteemed of a very ſuperior quality; and with reſpect to quantity, it yields a much larger than any other plant that is known in cultivation.

With all theſe great advantages it may be aſked, why are Britiſh farmers ſo blind to their intereſts to neglect the culture of this valuable plant? The reaſon we ſuppoſe ariſes from the great trouble and expence requiſite to keep it in proper order, without which it is in vain to attempt the growth of Lucerne.

It has been frequently tried in the common broad-caſt method, but always failed; drilling and hoeing are abſolutely neceſſary, and to this expenſive management a large quantity of the beſt mauure muſt be added annually, otherwiſe Lucerne will not flouriſh.

The proper ſeaſon to plant Lucerne is in April, and the only method by which any ſucceſs can be expected is to drill it in rows of two feet diameter, or upwards. As ſoon as it has grown a ſmall height, it ſhould be cleaned with the hand hoe from weeds, and the plants ſhould be thinned in the row, leaving thoſe which appear the moſt promiſing at about ſix inches diſtance from each other. After this, Lucerne is principally kept in order, and cultivated with the horſe hoe at leſs expence. Manure is generally laid in the intervals in winter, and by ploughing gradually brought to the roots of the plants. Its great uſe is to give green to cattle in the ſtable or elſewhere, for which it has no equal.

The proper time to cut Lucerne is before the bloſſom begins to open, and cannot be performed ſo well with any inſtrument as a reaping hook.

We would not recommend the culture of this valuable plant to any perſon who will not determine with themſelves to give it the greateſt attention, and ſpare neither expence in labour or manure, for without theſe it cannot anſwer, and with them it will.

R. Legrand, Eſq. obſerves, that he manured an acre of Lucerne, which he has in cultivation, with forty buſhels of ſoot annually, and does not repent his management: at this rate the produce muſt be prodigious.

SECT. X.

OTHER GRASSES NOT IN GENERAL USE, AND THEIR CULTIVATION.

We ſhall commence this ſection with an account of ſix valuable *Britiſh Graſſes*, collected and brought into cultivation by the ingenious Mr. Curtis of Lambeth Marſh, author of the Flora Londonienſis, and that much admired work the Botanical Magazine now publiſhing.

It is with the greateſt pleaſure we inform our readers that Mr. Curtis has not only favoured us with the following valuable deſcription of the Graſſes now before us; but will likewiſe render us every aſſiſtance in his power in the Botanical department of our work.

ON THE ADVANTAGE WHICH MAY RESULT FROM THE INTRODUCTION OF THE SEEDS OF OUR BEST GRASSES.

THAT much of our meadow and paſture land may be rendered infinitely more valuable than it is at preſent, by the introduction of ſome of our beſt Graſſes, is an opinion which has long prevailed among many of the more enlightened agriculturiſts of the preſent age. And while ſome of theſe have endeavoured to excite the huſbandman to collect and cultivate ſeeds of this ſort, by writings fraught with the ſoundeſt reaſoning; others have attempted to attract him by the offers of well-directed premiums. But, hitherto, neither the writings of the one, however convincing, nor the premiums of the other, however alluring, have been productive of the deſired effect: Ray-Graſs ſtill continues to be the only Graſs whoſe ſeeds can be purchaſed for the purpoſe of laying down meadow and paſture land; and how inadequate that Graſs is for ſuch a purpoſe, is known to every intelligent farmer. Why indeed the *Lolium perenne*, or Rye-Graſs, ſhould originally have been made uſe of, in preference to all the other Graſſes, cannot, perhaps, be ſatisfactorily accounted for; moſt probably it owes its introduction to accident, or to its being a common Graſs whoſe ſeeds were eaſily collected, rather than to its being preferred from an inveſtigation of its merits compared with the others; however this may be, there appears to be no reaſon for excluding the others, for it would appear exceedingly improbable that of upwards of a hundred Graſſes growing wild in this country, the Author of Nature ſhould have created one only as ſuitable to be cultivated for paſturage or fodder.

The difficulty of diſtinguiſhing the Graſſes one from another, has no doubt proved one grand obſtacle; many of theſe plants are ſo much alike, that the moſt diſcerning botaniſt is often at a loſs to know ſome of them apart; if ſo, how eaſily may the huſbandman be deterred from the arduous taſk.

From the numerous applications made to me, by a variety of gentlemen, for Graſs Seeds, it has appeared incumbent on me to do ſomething which might gratify them, and render the public an eſſential ſervice; I wiſh, at leaſt, to put it into their power to decide on a matter which has been long agitated, and from which I am far from being the only one that entertains the moſt ſanguine hopes of its proving a great national advantage.

The Graſſes recommended will, I am certain, do all that *our natural Graſſes* can do: they are ſix of thoſe which conſtitute the bulk of our beſt paſtures; moſt of them are early, all of them are productive, and they are adapted to ſuch ſoils and ſituations as are proper for meadows and paſtures.

But let no one expect them to perform wonders; for, after all, they are but Graſſes, and, as ſuch, are liable to produce great or ſmall crops, according to particular ſeaſons, or to the fertility or barrenneſs of the ſoil on which they are ſown.

OBSERVATIONS ON THE GRASSES RECOMMENDED

I. ANTHOXANTHUM ODORATUM. *Sweet-Scented Vernal-Graſs. Fig.* 1.

NEXT to the *Cynoſurus Cæruleus*, or *Blue Dogs-Tail Graſs*, this, of all our Engliſh Graſſes, comes firſt into bloſſom; it is therefore valuable as an early Graſs; it is valuable alſo for its readineſs to grow in all kinds of ſoil and ſituation, being found in bogs, in woods, (eſpecially ſuch as are of low growth, or have had the underwood cut down) in rich meadows, and in dry paſtures: in point of crop, it is not ſo productive as ſome, yet more ſo than others; cattle appear to be fond of it; and it is well known to be the only Engliſh Graſs which is odoriferous; the agreeable ſcent of new-made hay ariſes entirely from this Graſs, hence its name of *odoratum*, or ſweet-ſcented; the green leaves, when bruiſed, readily impart this perfume to the fingers, by which means the foliage may at all times be known; and perſons not deeply ſkilled in botany, may diſtinguiſh it when in bloſſom, by its having only two threads or ſtamina to each flower.

Of the ſeveral Graſſes here recommended, it is the leaſt productive in point of ſeed.

II. ALOPECURUS PRATENSIS. *Meadow Fox-Tail Graſs. Fig.* 2.

PRODUCES its ſpike almoſt, and in ſome ſituations, to the full, as early as the *Anthoxanthum*; hence it is equally valuable as an early Graſs; and as it is much larger, and quicker in its growth, it is conſequently much more productive: it ſhoots very rapidly after mowing, producing a very plentiful aftermath: and where land is rich, and two crops are not thought too much for it to bear, of all our Engliſh graſſes this appears to be the beſt adapted to ſuch a purpoſe, and ought to form a principal part of the crop: its foliage may, perhaps, appear coarſe to ſome, but it ſhould be remembered, that no Engliſh Graſs can be productive that is not in ſome degree coarſe; but if mown early, juſt as it comes into bloom, though the leaves are large, the hay will not be coarſe; in general, the great advantage ariſing from the earlineſs of this and the preceding Graſs is entirely loſt at a diſtance from London, where hay-making commences late, and where the huſbandman ſeems to wait for a crop of general indiſcriminate herbage, rather than of Graſs.

The *Meadow Fox-Tail* is more confined as to its place of growth, growing naturally in a moiſt ſoil only; hence it is beſt adapted to improve very wet ground that may be drained of its ſuperfluous moiſture, or to form or meliorate meadows that have a moiſt bottom, and are not apt to be burnt up in dry ſummers.

Its ſeeds are eaſily collected, but a great number of them, we believe, at leaſt one-third, are yearly deſtroyed by a very minute orange-coloured larva or maggot, which feeds on the embryo of the ſeed, and produces a very ſmall muſca or fly, probably the *Muſca Frit* of Linnæus.

This Graſs is diſtinguiſhed, in ſome degree, by the largeneſs of its foliage, and by its producing a ſoft ſpike on a long ſtalk early in May. The *Meadow Cats-Tail Graſs* produces a ſpike ſomewhat ſimilar, but rougher to the touch, and much later in the ſummer.

III. POA PRATENSIS. *Smooth-Stalked Meadow-Graſs. Fig.* 3.

THE foliage of this Graſs begins to ſhoot, and to aſſume a beautiful verdure very early in the ſpring, but its flowering ſtems are not produced ſo ſoon, by at leaſt a week, as thoſe of the *Alopecurus*; this trifling difference, however, in point of earlineſs of flowering, does not prevent it from ranking very properly with the two preceding; and, where early graſſy paſturage is a deſideratum, we are of opinion it cannot better be obtained than by a combination of theſe three; if crop be at the ſame time an object, the *Meadow Fox-Tail Graſs* ſhould predominate.

This Graſs rather affects a dry than a moiſt ſituation, and hence it keeps its verdure in long-continued dry weather better than moſt others, but it will thrive in either; will grow on the top of a dry wall, but grow much more luxuriantly in a rich meadow: it is to be obſerved, however, that it has a root which creeps like the *Couch Graſs*, and is almoſt as difficult to extirpate; it ought therefore to be cautiouſly introduced where the paſturage is not intended to be permanent.

Of the trifling improvements which we flatter ourſelves to have occaſionally made in ſome of the ſpecific characters of the Engliſh plants, none have given us more ſatisfaction than thoſe which relate to this ſpecies and the *Poa Trivialis*, two Graſſes ſo very ſimilar, as ſcarcely to be diſtinguiſhed, even by the moſt diſcerning eye, at a little diſtance, and very obſcurely characteriſed by Linnæus, but which, by attending to two characters only in each Graſs, may now, in a moment, be diſtinguiſhed by the utmoſt facility and certainty.

The *Poa Pratenſis* has a ſmooth ſtalk, the *Trivialis* a rough one, perceptible when drawn betwixt the thumb and finger, and which ariſes from little ſharp points, viſible when the ſheath of the leaf which covers the ſtalk is magnified, the *Trivialis* has a long pointed membrane at the baſe of the leaf, the *Pratenſis* a ſhort blunt one. Theſe Graſſes differ ſpecifically in a variety of other particulars, not neceſſary here to dwell on; and which ſuch as wiſh to be more particularly informed of, may conſult the Flora Londinenſis.

IV. Poa Trivialis. *Rough-Stalked Meadow-Graſs. Fig.* 7.

SIMILAR as this Graſs and the preceding are in their appearance, particularly in their mode of flowering, they differ very eſſentially in their qualities. While the *Smooth-Stalked Meadow-Graſs* is found chiefly in dry paſtures, the *Rough-Stalked* principally occurs in moiſt meadows, or on the edges of wet ditches; it loves moiſture, and a ſituation that is rather ſhady; hence, though there are few Graſſes more productive, or better adapted, for hay or paſturage, it is a tender Graſs, and liable to be injured by ſevere cold, or exceſſive drought: in very wet ground near the Thames, we have obſerved it grow very tall, while in poor land we have, on the contrary, ſeen it altogether as diminutive; it is, perhaps, no ſmall recommendatien to it that it is a principal Graſs in that uncommonly productive meadow near Saliſbury, mentioned by Stillingfleet, and more particularly deſcribed in the Memoirs of the Bath Agricultural Society, Vol. I. p. 94.

We may remark that the ſeeds of the *Poa Trivialis* and *Poa Pratenſis*, but more eſpecially thoſe of the former, are apt to be entangled and adhere to each other, as if cobwebs had been intermixed with them.

V. Festuca Pratensis. *Meadow Feſcue-Graſs. Fig.* 8.

OF the ſeveral Graſſes here recommended, this comes the neareſt in its appearance to the Ray-Graſs, to which, however, it ſeems to us, in many reſpects, to be greatly ſuperior, at leaſt, for the purpoſe of forming or improving meadows; it is larger, and more productive of foliage; it is ſtrictly perennial, it is very hardy, and will thrive not only in very wet, but alſo in dry ground: we have found it growing in all ſituations, from the ſand-pits at Charlton to the oſier-grounds at Batterſea; and it abounds in the very beſt meadows about London; in ſhort, we know of no graſs more likely to ſupply the deficiencies complained of in Ray-graſs; and yet it has not, that we know of, been particularly recommended. One quality it has, which bids fair to introduce it quickly into more general uſe; it produces more ſeeds than any of the others, which are eaſily gathered, and readily grow. In one reſpect, it is inferior to the three firſt Graſſes; it does not produce its flowering ſtems earlier than about the middle of June, a fortnight or three weeks later than the *Meadow Fox-Tail Graſs*, yet it cannot be conſidered as a late Graſs, as moſt of the Agroſtis tribe, and the *Meadow Cats-Tail Graſs*, flower at leaſt three weeks later. It muſt be carefully diſtinguiſhed from the *Feſtuca Elatior* or *Tall Feſcue-Graſs*, which is a very ſimilar but much coarſer Graſs.

VI. Cynosurus Cristatus. *Creſted Dogs-Tail Graſs. Fig.* 9.

IT is chiefly from the great character which this Graſs bears as a favourite and wholeſome food for ſheep, and from its being found in our ſoundeſt and beſt paſtures, that it is here recommended. It grows naturally in dry ſituations, and will not thrive in meadows that are very wet: it flowers about the ſame time as the *Meadow Feſcue-Graſs*, and is not very productive of foliage. As its flowering ſtems are always left untouched by cattle, its ſeeds may eaſily be collected where the paſturage is fed, not mown.

Of the ſaid SIX GRASSES, it will appear that the

Meadow Fox-Tail, and Rough-Stalked Meadow-Graſs	are fitteſt for	Moiſt Land.
Meadow Feſcue, and Sweeet-Scented Vernal		Land either moiſt or moderately dry.
Smooth-Stalked Meadow-Graſs, and Creſted Dogs-Tail		Dry Paſture.

The ORDER of their FLOWERING.

1. Sweet-Scented Vernal.
2. Meadow Fox-Tail.
3. Smooth-Stalked Meadow.
4. Rough-Stalked Meadow.
5. Meadow Feſcue.
6. Creſted Dogs-Tail.

We could eaſily add many more Graſſes to this liſt, and thoſe too which, perhaps, may be highly deſerving of it; but we have our doubts, whether, by recommending more, we might not increaſe the difficulty of introducing Graſs ſeeds without any adequate advantage.

Directions for Sowing the GRASS SEEDS above deſcribed.

IF a piece of ground can be had, that is neither very moiſt nor very dry, it will anſwer for all the ſeeds; they may then be ſown on one ſpot: but if ſuch a piece cannot be obtained, they muſt be ſown on ſeparate ſpots, according to their reſpective qualities, no matter whether in a garden, a nurſery, or a field, provided it be well ſecured and clean. Dig up the ground, level, and rake it, then ſo each kind of ſeed thinly in a ſeparate row, each row about a foot apart, and cover them over lightly with the earth: the latter end of Auguſt, or beginning of September, will be the moſt proper time for this buſineſs. If the weather be not uncommonly dry, the ſeeds will quickly vegetate, and the only attention they will require will be to be carefully weeded: in about a fortnight from their coming up, ſuch of the plants as grow thickly together may be thined, and thoſe which are taken up tranſplanted, ſo as to make more rows of the ſame Graſs.

If the winter ſhould be very ſevere, though natives, as ſeedlings, they may receive injury, therefore it will not be amiſs to protect them with mats, fern, or by ſome other contrivance.

Advantage ſhould be taken of the firſt dry weather in the ſpring, to roll or tread them down, in order to faſten their roots in the earth, which the froſt generally looſens: care muſt ſtill be taken to keep them perfectly clear from weeds. As the ſpring advances, many of them will throw up their flowering ſtems, and ſome of them will continue to do ſo all the ſummer. As the ſeed in each ſpike or panicle ripens, it muſt be very carefully gathered, and ſown in the autumn, at which time the roots of the original plants, which will now bear ſeparating, ſhould be divided and tranſplanted, ſo as to form more rows; the roots of the *Smooth-Stalked Meadow-Graſs*, in particular, creeping like *Couch-Graſs*, may readily be increaſed in this way; and thus, by degrees, a large plantation of theſe Graſſes may be formed, and much ſeed collected.

While the ſeeds are thus increaſing, the piece or pieces of ground which are intended to be laid down, ſhould be got in order. If very foul, perhaps, the beſt practice (if paſture land) will be to pare off the ſward and burn it on the ground; or, if this ſhould not be thought adviſeable, it will be proper to plough up the ground and harrow it repeatedly, burning the roots of *Couch-Graſs*, and other noxious plants, till the ground is become tolerably clean; to render it perfectly ſo, ſome cleanſing crop, as potatoes or turnips, ſhould be planted or ſown.

By this means, the ground we propoſe laying down, will be got into excellent order without much loſs; and being now ready to form into a meadow or paſture, ſhould be ſown broad-caſt, with the following compoſition.

Meadow Fox-Tail, one pint.—*Meadow Feſcue*, ditto.—*Smooth-Stalked Meadow*, half a pint.—*Rough-Stalked Meadow*, ditto.—*Creſted Dogs-Tail*, a quarter of a pint.—*Sweet-Scented Vernal*, ditto.—*Dutch Clover* (*Trifolium Repens*) half a pint.—*Wild Red Clover* (*Trifolium Pratenſe*) or, in its ſtead, *Broad Clover of the Shops*, ditto.—For wet land, the *Creſted Dogs-Tail*, and *Smooth-Stalked Meadow*, may be omitted, eſpecially the former.

Such a compoſition as this, ſown in the proportion of about three buſhels to an acre, on a ſuitable ſoil, in a favourable ſituation, will, I am bold to aſſert, form in two years a moſt excellent meadow; and as all the plants ſown, are ſtrong, hardy perennials, they will not eaſily ſuffer their places to be uſurped by any noxious plants, which by manure or other means, in ſpite of all our endeavours, will be apt to inſinuate themſelves; if they ſhould, they muſt be carefully extirpated, for ſuch a meadow is deſerving of the greateſt attention; but if that attention cannot be beſtowed on it, and, in proceſs of time, weeds ſhould predominate over the crop originally ſown, the whole ſhould be ploughed up, and freſh ſown with the ſame ſeeds, or with a better compoſition, if ſuch ſhall be diſcovered; for I have no doubt but, at ſome future time, it will be as common to ſow a meadow with a compoſition ſomewhat like this, as it now is to ſow a field of wheat or barley.

Mr. Curtis has here laid before the public, information and inſtructions of the utmoſt importance, and has opened ſuch a field for agricultural improvement as will cauſe poſterity to revere his name.

BURNET.

Burnet is a plant which grows wild in many of our Engliſh meadows, and will likewiſe grow on very poor ſandy, or other dry ſoil, this makes it valuable. An anonymous correſpondent in the Bath Society's Papers, has given a very ſatisfactory account of Burnet from experiment, and which the Scotch Encyclopædia have quoted without an acknowledgment, and adopted it as their own; but ſuch plagariſm, we do not think liberal, and when we give any thing not our own, think it our duty to declare to whom we are indebted. The following is from the Bath Society's Papers, Vol. 2. p. 128.

" SIR,

" YOUR letter of December 20, reached me in due courſe, wherein you informed me that Burnet is a graſs but little cultivated in Somerſetſhire, and requeſt my thoughts on its uſefulneſs. I ſhall at all times be happy in communicating any thing that may tend to promote the views of a ſociety eſtabliſhed on ſo liberal a plan as that of Bath, and therefore it is with pleaſure that I comply with your wiſhes, ſo far as the knowledge of the ſubject will admit.

" Burnet is not generally cultivated in this county; but ſome of our moſt intelligent farmers have raiſed it, of late years, with conſiderable ſucceſs.

" I apprehend that one principal cauſe of its not having been more attended to, is the goodneſs of our ſoil, which will produce other crops that in general pay better than Burnet. But this is a reaſon which ought not to operate in countries which abound with poor land, to which this plant is better adapted than many others.

" The cultivation of this graſs is attended with one principal advantage, beſides that of not requiring a rich ſoil; which is, that it proves an excellent winter paſture when hardly any thing elſe vegetates.

" I might indeed mention ſeveral others; to wit, it makes good butter; it never blows or ſwells cattle; it is fine paſture for ſheep; and will flouriſh well on poor, light, ſandy, or ſtony ſoils, or even on dry chalk hills.

" The cultivation of it is neither hazardous nor expenſive. If the land is prepared, as is generally done for turnips, there is no danger of its failing. After the firſt year, it will be attended with very little expence, as the flat circular ſpread of its leaves will keep down, or prevent the growth of weeds.

" On the failure of turnips, either from the fly or the black worm, ſome of our farmers have ſown the land with Burnet, and in March following had a fine paſture for their ſheep and lambs. It will perfect its ſeed twice in a ſummer; and this ſeed is ſaid to be as good as oats for horſes; but it is too valuable to be applied to that uſe.

" It is ſometimes ſown late in the ſpring with oats and barley, and ſucceeds very well; but it is beſt to ſow it ſingly in the beginning of July, when there is a proſpect of rain, on a ſmall piece of land, and in October following, tranſplant it in rows two feet apart, and about a foot diſtant in the rows. This is a proper diſtance, and gives opportunity for hoeing the intervals in the ſucceeding ſpring and ſummer.

" After it is fed down with cattle, it ſhould be harrowed clean. Some horſes will not eat it freely at firſt, but in two or three days they are generally very fond of it. It affords rich pleaſant milk, and in great plenty.

" A gentleman farmer near Maidſtone, ſome years ſince ſowed four acres as ſoon as the crop of oats were got off, which was the latter end of Auguſt. He threw in 12 pounds of ſeed per acre, broadcaſt; and no rain falling until the middle of September, the plants did not appear before the latter end of that month. There was however a good crop, and in the ſpring he ſet the plants out with a turnip-hoe, leaving them about a foot diſtant from each other. But the drill method is preferable, as it ſaves more than half the ſeed. The land was a poor dry gravel, not worth three ſhillings an acre for any thing elſe.

" The ſevereſt froſt never injures this plant; and the oftener it is fed the thicker are its leaves, which ſpring conſtantly from its root."

In confirmation of the value of Burnet, Mr. Young obſerves, " that Mr. Coke, of Holkham, ſowed forty acres, mixing a ſmall quantity of white clover and rib graſs with it. The reſult was as ſatisfactory as can be poſſibly imagined; the field has been full ſtocked with all ſorts of cattle, eſpecially ſheep, and is conſtantly pared as cloſe to the ground, as a favourite ſpot in a paſture is by horſes."

Burnet from its warm aromatic quality is eſteemed very ſerviceable to ſheep, that are touched with the rot; but if any benefit is to be obtained, they ſhould be turned into a field of Burnet immediately on their coming from a ſuſpected paſture.

CABBAGE, TURNIP CABBAGE, AND RAPE, AND THEIR CULTIVATION.

The culture of Cabbages for the feeding of cattle it ſeems probable will never become general, as to grow them to perfection requires rich land, and the expence and trouble in preparing the land, and other contingencies, is very conſiderable.

On lands that will produce full crops of them, Cabbages are certainly cultivated to great advantage: the kind of ſoil is not material, provided it is in good tillage, and capable of producing ſtrong luxuriant crops.

As it is neceſſary we ſhould preſent our readers with directions for raiſing, and applying them to the purpoſes for which they are beſt ſuited, we cannot do it in a more conciſe and practical manner than by the following extract from Mr. Young's Annals, vol. III. p. 183.

ON THE CULTURE OF CABBAGES.

By Mr. William Green, *of Sutton Hall, near Bury, Suffolk.*

" SOW the ſeed on a very rich bed the beginning of March; 1 ℔ of ſeed on 10 rods of ground for three acres; the ſort drumhead, from its flat top, and as hard as a ſtone; price of the ſeed 2s. 6d. per ℔. this better than the tallow-loaf, heavier and harder. The land where they are to be planted to be ploughed up at Michaelmas; let it lie till ſpring; plough four or five times; dung before the laſt ploughing; 15 load (three horſes) an acre dung, or 20 dung and earth; plough it on three-feet ridges the latter end of June ready to plant, that is to wait for rain. Much depends on having large ſtout plants; the ſeed-bed is therefore drawn; when rain comes all hands to work. The expence is about 3s. an acre planting. In about a month plough between, by drawing the lands into balks, and then ſhut up, after which hoe with hand-hoes; but do not hand-hoe before ſhutting up, for by the hoe following the plough the clods which roll on to the plants are eaſily removed; another reaſon is, the ſpace of land on which the plants ſtand after drawing out, being too narrow to bear a hoeing. Hand-hoe thrice, each time 2s. an acre, 6s. in all. I have cultivated them ſix years, and never loſt a crop but once for want of rain.

" About three weeks after planting, taking the opportunity of rain, replant the vacancies from failure.

" Begin to uſe them a month after Michaelmas for milch cows, and keep uſing them ſo till the end of March; but they ought to be off the land the middle of that month, as they then ſhoot and draw the land. Three good acres will do for my dairy of 20 cows, with ſtraw and ſome hay; but if abſolutely no hay, then five acres of cabbages. For weanling calves they are moſt excellent. Turnips are apt to give them the garget, by which they very commonly die; but in ſix years I have loſt only one calf in above 40, by feeding them on Cabbages, nor can any calves thrive better.

" In fattening beaſts, I find that a middling crop will fatten in the proportion of ¼ of an acre for two beaſts of 50 ſtone that have had the ſummer graſs.

" Hogs prefer them exceedingly to turnips; of this I have a ſtriking inſtance the preſent ſeaſon; for having a field part under turnips and part cabbages, my ſows, &c. have at various times this winter got into the field, and I do not think they have begun ten turnips in the whole field, but conſtantly got to the Cabbages.

" In regard to value, I have no poſitive data to calculate on, for it is not eaſy to keep accounts accurate enough to aſcertain it, but in a general way, reckon a good acre worth from 4 to 5l. or, more generally, to be double the value of turnips.

" I am ſenſible that this practice leaves the farmer without cabbage aſſiſtance for a month or ſix weeks in the ſpring; part of this time may be ſupplied by drawing Cabbages for about a fortnight after drawing; and the remainder by a practice which I have followed many years with ſucceſs. It is to keep about 20 acres of my meadow rouen (after graſs) till April, never turning any thing in from the ſcythe till that time. This is excellent for cows, for ewes, and lambs, eſpecially crones; and I believe it will be found (it has proved ſo with me) that any piece of rouen that is worth 5s. at Michaelmas, will be worth 10s. in April, and ſo in other proportions; but the value will depend a good deal on the weather; in a dry time it goes very far, but in a wet ſeaſon it is much ſpoiled. Let it alſo be remembered, that this graſs is ſaved from a ſeaſon (autumn) when food is exceedingly plentiful, and of little value to thoſe who do not ſell.

AGRICULTURE.

Expences of an Acre of Cabbages.

	£.	s.	d.
Rent	0	10	0
Tythe	0	1	6
Poor rates	0	1	3
Five ploughings	1	0	0
Two harrowings	0	0	6
Manuring	2	0	0
Seed-bed ſeed, &c.	0	1	6
Planting	0	3	0
Deficiencies	0	0	6
Hand-hoeings	0	4	0
Horſe-work in hoeing	0	4	0
Cutting and carting ¼ of a mile . .	0	15	0
	5	1	3

" This is giving the total expence of the manure to the Cabbages; but if the advantage is divided, as it certainly is, then not more than 15s. ſhould be laid to the crop, which will make the total expence 3l. 16s. 3d.

" The barley or oats that follow Cabbages, have been thought by ſome to be inferior to that which ſucceeds turnips, but in my experience I have not found it ſo, for I have ſeveral times had turnips and Cabbages in the ſame field equally dunged, and the ſoil and management the ſame, but I have found that that crop gives the beſt barley which is taken off earlieſt.

Sutton-Hall, Feb. 17, 1785. W. G."

This explicit and excellent account of the cultivation of Cabbages for the purpoſes of Agriculture is as much as can be ſaid on the ſubject, were volumes wrote upon it. We can only remark, that in Mr. Green's calculation of expences, we think him below the mark in the articles Rent and Labour; but countries differ in theſe matters conſiderably.

TURNIP CABBAGE.

Turnip Cabbage, or Turnip-rooted Cabbage, ſhould be ſowed on rich good land about the time which is deemed proper to plant the common turnip, and ſhould be hoed and managed in the ſame manner.

The importance which Turnip-rooted Cabbage claims as a valuable appendage to huſbandry, is by retaining their good qualities when the common turnip becomes of little value.

The following ſhort letter by Sir Thomas Beevor, Bart. to the Secretary of the Bath Society is a proof of their excellence.

ON THE VALUE OF TURNIP-ROOTED CABBAGE AS A SPRING CROP.

" MY Turnip-rooted Cabbages are now in high perfection. I have about three acres left, with which I am feeding 22 bullocks intended for fattening this ſummer, 17 cows, 2 bulls, 4 young cattle, and 110 ſheep, beſides 30 horſes, which partake largely of them. I hope and expect they will yet laſt near a fortnight more, by which time I doubt not but I ſhall have a full and plentiful bite of graſs for all my ſtock. In order to aſcertain, in ſome degree, the quantity of food they produced, I carefully ſelected ſome of them, and ſome of the common turnips; and having girted each of them with as much accuracy as poſſible, I found the Turnip-rooted Cabbage at the circumference of 18 inches, weighed 5℔¼, and the common turnip of the ſame circumference 3℔½ only. I took others of different dimenſions, and found throughout, the reſult to be in that proportion: they were all without their tops, otherwiſe the exceeding of the Turnip-rooted Cabbage would have been greater, the leaves of them being remarkably buſhy. It muſt, however, be mentioned, that thoſe roots were weighed at the latter end of March: had they been weighed at Chriſtmas it is likely the difference had not been ſo great: ſtill, their late continuance for a green and moſt nouriſhing food is indiſputably a merit they muſt be allowed beyond any other known vegetable production.

" I am with regard, Your's, &c.

Hethel, May 1. THOMAS BEEVOR."

As Turnip-rooted Cabbages occupy the ground till the ſeaſon becomes too far advanced for barley ſowing, Sir Thomas Beevor, and other cultivators of the Turnip Cabbage, ſow inſtead of barley, buck-wheat, and with it graſs ſeeds: this nouriſhes the graſs ſeeds, and produces a profitable meliorating crop, alſo keeps the land in its proper courſe of tillage.

RAPE.

Rape, or Cole, is generally cultivated on account of the ſeed, from which a large quantity of oil is extracted; for this purpoſe it is generally ſowed in June, in the ſame manner, and the ſame quantities of ſeed to the acre, as turnips.

About the middle or latter end of Auguſt the plants ſhould be hoed, and left ſtanding from twelve to ſixteen inches aſunder; by no means leave them thicker; this, if well performed, will coſt four or five ſhillings per acre.

Should any part miſs, it will be requiſite to fill up the vacancies by tranſplanting from other parts of the field, which are too thick, in October.

The following Auguſt Rape becomes fit to cut and harveſt; great attention is neceſſary to preſerve it from birds; thoſe which are called finches in particular.

It is generally thraſhed in the field, as ſoon as it is ſufficiently dry after it is cut; and great care muſt be taken in collecting it together, at the time it is carried to the thraſher, which is performed with cloths brought into the field for that purpoſe.

The quantity on good land varies from thirty to forty buſhels per acre, and the uſual price for good back ſeed, is about ſix ſhillings and ſix pence per buſhel.

Let it be noticed that Rape for ſeed ſhould be ſowed on freſh rich land; and if on an inferior ſoil, it ſhould be on ſuch as is freſh broke up from graſs. Rape is occaſionally mixed with late ſowed turnips, deſigned for ſpring feed, and anſwers the purpoſe very well.

SECT. XII.

TURNIPS AND THEIR CULTIVATION.

TURNIPS are of the greateſt conſequence in Britiſh Agriculture, as ſuch we preſent the public with a particular account of their cultivation from Mr. Young's Annals, Vol. 3. Page 297; without flattering the author, we pronounce his account really inſtructive.

THE CULTURE OF TURNIPS, RECOMMENDED TO THOSE COUNTIES WHERE THEY ARE NOT YET COMMON.

By Mr. W. Macro.

THE Turnip culture being the beſt winter proviſion for almoſt all kind of ſtock, and yet very little known in ſome counties in England, where I think it might be practiſed to great advantage, I will, under the different titles of ſoil, tillage, &c. give an account of the Suffolk manner of managing that uſeful root.

SOIL.

The right ſoil for this root is a deep ſand, ſuch as has adheſion enough to make it of the value of from 5s. to 10s. an acre, land of 14s. or 15s. has generally too great a mixture of loam; for, if the land is wet or ſtiff, ſuch as yield good wheat-crops, the culture may not be advantageous, eſpecially if uſed, as it ſhould be, as a preparation for barley: on ſuch ſoil it would ſhorten the crop at leaſt 10 or 12 buſhels an acre; I ſhould ſooner prefer blowing ſands of 3s. 6d. and even 2s. 6d. per acre, which, when folded, and the ſeaſon happens to be wet, yield profitable crops; indeed, ſuch lands can be farmed no other way, for, if no turnips are gained, no corn will be had; and a mere ſheep-walk is then the only uſe that can be made of them. Where a farmer has no proper ſoil for Turnips, I think it would be prudent to give up the winter-feeding of more cattle than his hay and ſtraw will do for, unleſs he depends on buying Turnips, which may ſometimes be advantageous, and ſometimes the contrary. I will juſtly obſerve, that I have a neighbour upon a wet ſoil, with about 30 ſcore very fine ſheep, who, one year with another, cannot grow 20 acres of turnips, but depends on buying of his neighbours.

TILLAGE.

The firſt earth ſhould be given before Chriſtmas, of a common ſtaple depth; and if, before the ſpring ſeed-time, a ſecond earth can be given, it will be very uſeful; for, if there ſhould be any ſpear-graſs in the land, that pernicious weed is apt to get too great a hold before barley-ſowing is over; immediately after the barley is in, the third earth ſhould be given, this will be in May; the fourth about the ſecond week in June; and the fifth, or ſeed-earth, the latter end of the ſame month, unleſs the ſoil is ſubject to the mildew, in which caſe old Midſummer will be full ſoon enough. And let it be obſerved, that harrowing with every earth is very neceſſary, for the ſurface ſhould always be kept in fine friable order, that the ſeed-weeds may grow, otherwiſe, if that is omitted, till the ſeed-earth, they will then grow ſo powerfully as to ſmother many of the young plants.

MANURE.

For Manure we depend on the fold or farm-yard, uſually both; of farm-yard dung not leſs than 12 loads ſhould be ſpread on an acre, ſuch as was made the preceding winter, and once turned over. In reſpect to the length of dung, it ſhould neither be long nor quite rotten; the beſt condition is, when it is in ſuch a ſtate that the labourers ſay it will neither ſpit nor fork. I never tried any other Manure for this root, except once an experiment on ſhell marle from Woodbridge-ſide, called there *crag*. I had ſeen ſuch great effects there from it, that, through curioſity, I brought a waggon load (back carriage) and tried it on a light turnip ſoil, and alſo on a good ſtrong loam, and it was with great ſurpriſe I found that it did ſcarcely any good on either: the advantage was, if any thing, rather greater on the former, but not ſufficient to induce me to carry it a ſingle mile had a crag pit been found on the farm. When the dung for turnips is rather long and ploughed in with the ſeed earth, the ſeed ſhould be only rolled in.

SEED.

The quantity of ſeed depends on the ſoil; upon a naturally good Turnip ſand a pint an acre, evenly delivered by a good hand, or ſowing engine, will be enough; no ſoil demands ſo much ſeed as chalky land when the chalk comes quite to the ſurface; upon ſuch ſoil, a quarter of a peck an acre will ſeldom be too much, the reaſon of the difference is, that the fly is ſure to attack the plants upon this ſoil much more voraciouſly and with greater certainty than on any other. I do not, therefore, recommend this ſoil for Turnips in general, but where it ſo happens, that one end, or one ſide of a piece of Turnip land is of this ſort (which is often the caſe) to be careful to lay the ſeed thick enough on thoſe parts.

Having mentioned the ſowing-engine, I ſhould remark, that though it is with care a good tool, yet it is liable to have the holes ſtopped by two ſeeds ſticking in them, ſo that if the ſeedſman is not very attentive, he may go ſome diſtance without a regular delivery.

The ſeaſon for ſowing extends from New-Midſummer to the end of July, this variation is neceſſary for two reaſons; firſt, becauſe the land cannot be all manured to ſow early; and, ſecondly, becauſe the late ſown will laſt much longer than the early ones, which are apt to mildew, and conſequently more likely to be rotted by hard froſts afterwards, for which reaſon, all farmers ſhould take care to have ſome late ſown; I have had them from a ſowing the firſt week in Auguſt, which proved the moſt profitable crop on my farm, owing to the froſt killing others while theſe eſcaped.

HOEING.

Hoeing is ſo eſſential towards getting a good crop, that I am ſurpriſed a farmer ſhould think of ſowing them with any other view. As ſoon as the plants are ſtout enough they ſhould be harrowed with a light harrow once in a place, this aſſiſts the hoeing; it is not eaſy to deſcribe the ſtate of the plants when they are ready for the hoe, age will not diſcriminate, becauſe the ſeaſon will vary from three weeks to eight, and even nine from the time of ſowing; but a better rule is, to begin when the plants in general ſpread a circle of about four inches diameter. If any of the fields, after the hoeing begins, are getting too forward, which in a wet ſeaſon is often the caſe, a ſecond harrowing (the contrary way) may ſafely be given.

I find, by ſowing my Turnips at different ſeaſons, that ſix men will hoe 100 acres twice; but thoſe who do not equally vary their ſeaſons, muſt of courſe proportionally increaſe the number. The ſecond hoeing is given about a fortnight or three weeks after the firſt, at half the expence, that is 2s. an acre; this is ſometimes omitted, but it anſwers exceedingly well.

APPLICATION OF THE CROP.

In regard to conſuming the crop, I would recommend feeding ſheep with them upon the land as by far the beſt preparation for barley, provided the ſoil is true turnip-land, that is dry. The benefit will, however, vary with the time of eating off, for thoſe that are eaten early in the winter, will not, by any means, give ſo good barley as thoſe which are eaten later, provided the plants do not run for bloſſom, for then they exhauſt the land, and the ſucceeding crop ſuffers. Carting off is common, but the expence, allowing for the damage done to the ſucceeding crop, is too great, and I ſhould never recommend the culture with that view.

ACCIDENTS.

It is neceſſary to ſay ſomething on the failures that Turnip crops are liable to, which are the fly, the mildew, the black canker, and to rotting from froſt. I calculate that the froſt deſtroys half the crop once in ſix or ſeven years; the fly not only deſtroys ſome crops entirely, but even when a ſecond or third ſowing yields ſomething, it is gained at the expence of one or two plowings, harrowings, and ſeed, when no tillage is wanting for the land; this may, on an average, be calculated to amount to the loſs of a whole crop once in five or ſix years; the mildew is rather connected with the rot, and the black-canker has not yet been ſo common with us as to demand a particular calculation.

I would, for the above reaſons, notwithſtanding all the praiſe that is due to this moſt uſeful root, recommend to all ſheepmaſters, eſpecially thoſe with breeding-flocks, not to truſt ſingly to them. I have found very great advantage from having certain breadths of cole-ſeed, rye, and winter tares ſown early on the firſt ſtubbles that were cleared the preceding autumn; indeed, ſuppoſing no failures, it is abſolutely neceſſary to have ſome ſuch proviſion for the couples, by the time the lambs begin to feed, as it will put them on a great deal faſter than the beſt turnips that can be given.

Mr. Macro's ideas on the cultivation of Turnips are certainly replee with uſeful and practical information, as much ſo, we are of opinion, as ever appeared in print; our obſervations will therefore be conciſe.

Mr. Macro is certainly right in cultivating Turnips on ſandy land, but we cannot think ſoil, of the deſcription he mentions, will produce them in any quantity to be of ſervice, either to the land by eating off, or pay expences by the Turnip or the future crops; except the ſandy ſoils in Suffolk are let cheaper than they are in the North and Weſt parts of the kingdom.

For we have never ſeen blowing ſands of 2*s*. 6*d*. or 3*s*. 6*d*. per acre, that would repay expenſive cultivation, without there was ſome peculiar advantage in the ſituation, with reſpect to manure or other local circumſtances.

We beg leave alſo to deſcend from Mr. Macro, when he calls ſand the moſt proper ſoil for Turnips, as we have generally found from practice and obſervation, that a braſhy limeſtone loom, not too thin in the ſtaple, has produced Turnips, and the ſucceeding crops to more advantage than ſandy land of equal value.

With reſpect to feeding Turnips off the land, the beſt method both for the ſheep and land is by means of hurdles, to be removed in part, in ſuch a manner as they may have them freſh every day; by this means they eat the Turnips clean, the land is regularly manured, and the ſheep fare every day alike.

As many countries do not purſue this method, we think thoſe who do not, loſe a great part of the benefit belonging to the Turnip crop; and would by all means recommend the practice. In Turnip countries we preſume the method of giving ſheep their feed every day is general; as ſuch we refer thoſe who want information to thoſe countries: a ſhepherd will remove a quantity of hurdles ſufficient to give 200 ſheep their feed in an hour.

Turnips, in their infant ſtate, are always in a precarious ſituation with reſpect to the fly or ſlug, they will perhaps appear promiſing and in good condition one day, and on the morrow be all deſtroyed.

Mr. Vagg, of Chilcampton, aſſured the public by advertiſement and other means of diſtributing information, that he was in poſſeſſion of an infallible receipt for the protection of young turnips from the fly, and that he would diſcover it to the public, provided a thouſand perſons would ſubſcribe two guineas each; this we have been informed was effected; and the great and important ſecret was diſplayed to the world: which was nothing more than this, "when the turnips are ſuſpected to be in danger from the fly or ſlug, cauſe a heavy roller to be drawn over them in the night, repeating the ſame every night till you think them ſafe."

This remedy, if effectual, is eaſily performed, and at a ſmall expence; and if Mr. Vagg is in poſſeſſion of the 2000 l. we give him joy! And ſhould our readers wiſh to know how he came by the ſecret, we beg leave to refer them to a Treatiſe on Agriculture, wrote in the year 1744, called MODERN HUSBANDRY, page 131, by William Ellis, who ſold the ſecret Mr. Vagg has adopted as his own legitimate offspring, and a number of others of equal importance, for no more than TWO SHILLINGS.

Amongſt our implements of Huſbandry, we ſhall give a new invented and ingenious inſtrument for tranſplanting Turnips; to that Section we refer our readers for a deſcription.

SECT. XIII.

POTATOES AND THEIR CULTIVATION.

POTATOES are a root of ſuch ineſtimable value, as food for the human ſpecies and the brute, that in all probability ages to come will be amazed to think, how it was poſſible the inhabitants of this country could ever have ſubſiſted without them.

They have been introduced into Britain upwards of two hundred years; the firſt century after they were known, (conſidering their preſent value) their general utility made a very ſlow progreſs indeed; to the inventive induſtry of the preſent age every praiſe is due which belongs to the cultivation of this uſeful root.

Moſt kinds of ſoil (ſtiff clay excepted) will produce Potatoes; a looſe ſandy loam ſeems the beſt adapted to grow them in large quantities, and of good quality: rich black loam will unqueſtionably yield the largeſt produce, and equally ſerviceable for cattle; but by no means pleaſant food for the table.

AGRICULTURE.

As good information, ſanctioned by practice, is what we communicate to the public, we truſt the following will prove highly acceptable; extracted from the Bath Society Papers.

ON THE CULTURE OF POTATOES.

By the Rev. H. J. CLOSE, Trimley, Suffolk.

" THE following practical obſervations on the culture and uſe of Potatoes, will not, I hope, appear entirely unintereſting. They are the reſult of various experiments made for five years ſucceſſively on that valuable root, the growth of which cannot be too much encouraged.

" When the Potatoe crop has been the only object in view, I have adopted the following method with the greateſt ſucceſs.

" The land being well pulverized by two or three good harrowings and ploughings, is then manured with fifteen or twenty cartloads of dung per acre, before it receives its laſt earth. Then it is thrown on to what the Suffolk farmers call the *trench balk*, which is narrow and deep ridge work, about fifteen inches from the center of one ridge to the center of the other.

" Women and children drop the ſets in the bottom of every furrow fifteen inches apart; men follow, and cover them with large hoes, a foot in width, pulling the mould down ſo as to bury the ſets five inches deep; they muſt receive two or three hand-hoeings, and be kept free from weeds; always obſerving to draw the earth as much as poſſible to the ſtems of the young plants.

" I find, by repeated trials, the firſt or ſecond week in April the moſt advantageous time for planting.

" In the end of September, or the beginning of October, when the haulm becomes withered, they ſhould be ploughed up with a ſtrong double-breaſted plough.

" The workman muſt be cautioned to ſet his plough very deep, that he may ſtrike below all the Potatoes, to avoid damaging the crop.

" The women who pick them up, if not carefully attended to, will leave many in the ground, which will prove detrimental to any ſucceeding corn, whether wheat or barley. To avoid which inconvenience, let the land be harrowed, and turn ſwine in to glean the few that may be left by their negligence.

" By this method, the ſets will be fifteen ſquare inches from each other; it will take eighteen buſhels to plant an acre; and the produce, if on a good mixed loamy ſoil, will amount to three hundred buſhels.

" If the Potatoes are grown as a preparation for wheat, I prefer having the rows two feet two inches from each other, hand-hoeing only the ſpace from plant to plant in each row; then turning a ſmall furrow from the inſide of each row by a common light plough; and afterwards, with a double-breaſted plough with one horſe, ſplit the ridge formed by the firſt ploughing thoroughly to clean the intervals.

" This work ſhould not be done too deep the firſt time, to avoid burying the tender plants; but the laſt earth ſhould be ploughed as deep as poſſible; and the cloſer the mould is thrown to the ſtems of the plants, the more advantageous it will prove. Thus fifteen buſhels will plant an acre, and the produce will be about three hundred buſhels; but the land, by the ſummer ploughings, will be prepared to receive ſeed-wheat immediately, and almoſt enſure a plentiful crop.

" The Potatoe ſets ſhould be cut a week before planting, with one or two eyes to each, and the pieces not very ſmall; two buſhels of freſh ſlaked lime ſhould be ſown over the ſurface of the land as ſoon as planted, which will effectually prevent the attacks of the grub.

" The expence attending an acre of Potatoes well cultivated in the firſt method, ſuppoſing the rent twenty ſhillings, tithe and town charges rather high, (as in Suffolk) taking up, and every thing included, will be about ſix pounds. In the laſt method, it would be ſomewhat reduced.

" I have many years ſold the greateſt part of my crops for ſeven ſhillings per ſack of three buſhels; thus the one hundred and twenty ſacks would amount to forty-two pounds; but they are now ſo much cultivated, that to make a fair, and what may be termed a ſure eſtimate, they ſhould be valued only as applicable to the feeding and fattening of cattle. I am convinced from experience, that they are worth three ſhillings per ſack for thoſe purpoſes, and then the produce would amount to eighteen pounds per acre.

" They are excellent food for hogs; roaſting pork is never ſo moiſt and delicate as when fed with Potatoes, and killed from the barn-doors without any confinement. For bacon and hams, two buſhels of pea-meal ſhould be well incorporated with four buſhels of boiled Potatoes, which quantity will fat a hog of twelve ſtone, (fourteen pounds to the ſtone). Cows are particularly fond of them: half a buſhel at night, and the ſame proportion in the morning, with a ſmall quantity of hay, is ſufficient to keep three cows in full milk; they will yield as much and as ſweet butter as the beſt graſs.

" In fattening cattle, I allow them all they will eat: a beaſt of about thirty-five ſtone will require a buſhel per day, but will fatten one-third ſooner than on turnips. The Potatoes ſhould be clean waſhed, and not given until they are dry. They do not require boiling for any purpoſe but fattening hogs for bacon, or poultry; the latter eat them greedily. I prefer the champion Potatoe to any ſort I ever cultivated. They do not anſwer ſo well for horſes and colts as I expected; (at leaſt they have not with me) though ſome other gentlemen have approved of them as ſubſtitutes for oats.

" When predilections for old cuſtoms are ſubdued, I hope to ſee the Potatoe admitted in the conſtant courſe of crops, by every ſpirited huſbandman. The moſt beneficial effects will, I am certain, accrue from ſuch a ſyſtem. The advantages in my neighbourhood are apparent; I cultivated, and fed my own children upon them, and my poorer neighbours ſenſibly followed the example. A great proportion of every cottager's garden is now occupied by this root, and it forms a principal part of their diet. Potatoes are cheap and excellent ſubſtitutes for peaſe in ſoups and broths, allowing double the quantity."

In addition to Mr. Cloſe's excellent and inſtructive leſſon, we give the account of Mr. John Bywell, of Aglethorp in Yorkſhire, on the uſe of Potatoes in feeding cattle. Annals of Agriculture, vol. I. page 402.

USE OF POTATOES IN FEEDING CATTLE.

By Mr. John Bywell, of Aglethorp, Yorkſhire.

" Four pecks, eight quarts to the peck, are ſufficient for a large beaſt, with a little hay, for 24 hours; they are ſuperior to turnips in feeding, one third, both uſed in equal time. They are given to milch cows with great advantage, and are healthy fother. They are very good for draught horſes, to give them half a peck a day with hay; I never had my horſes in ſo good condition as when fed with Potatoes: they are a certain remedy to a horſe with ſwelled legs, or out of condition (in other caſes and diſorders inwardly one peck a day) they are accounted good for hunters the day after they have had a ſevere run, to give them eight or ten large Potatoes. The number of buſhels of Potatoes grown on one acre are, upon an average, 360. I give them to cattle raw as taken out of the ground.

" The manner of management for potatoes, is to give the land three or four ploughings, and as many harrowings, 24 cart loads of horſe dung to an acre; when the furrow is drawn, the plants to be planted at 12 inches diſtance one from another, the labourers to ſpread the dung by hand, along the top of the plants, with a little lime: if lime cannot be had at the time of planting, it is proper to ſpread a little over the ground as they make their firſt appearance out of the earth, alſo to give them a light harrowing to mix the lime.

April 2, 1784. J. B."

Mr. Bywell likewiſe obſerves, a little hay is of great ſervice to the Potatoes in feeding cattle, and that half a peck of Potatoes, with hay every day, will keep a working horſe in good order.

Doctor James Anderson, by his ingenious experiments, has ſucceſsfully diſtilled Potatoes, and drawn from 72 pounds weight of that root a gallon of pure ſpirit conſiderably above proof, and a quart of a weaker kind a good deal below proof. This was, he obſerves, " the fineſt and moſt agreeable vinous ſpirit I ever ſaw. In taſte it reſembled very fine brandy, but was more mild than any brandy I ever taſted, and had a certain kind of coolneſs upon the palate peculiar to itſelf."

The following is an abridged account of the proceſs. The Potatoes were firſt boiled till they came to a pulpy ſtate, then bruiſed and made to paſs through a ſtrait riddle along with ſome freſh water, the ſkins being by this means ſeparated, were thrown away. The pulp was then mixed with cold water, till the whole amounted to about 20 gallons; this, when in a proper heat, had ſome yeaſt put to it, as for brewing. In the ſpace of ten or twelve hours a fermentation began, which continued twelve hours, and then abated. I warmed it a little, but in vain, then ſtirred it briſkly, which had the deſired effect, as the fermentation was renewed by that means. I uſed the ſame means every day, and it fermented a fortnight, and then ſtopped. The liquors having acquired a ſlight acidity, it was put into the ſtill, and ſtirred till it boiled; the ſtill head was then put on; it was then diſtilled with due caution, and produced the valuable ſpirit abovementioned.

As a further proof of the uſe of Potatoes, we give the following by John Kirby, Eſq. of Ipſwich, from Mr. Young's Annals, vol. I. p. 285.

EXPERIMENTS ON POTATOES.

By John Kirky, Esq. of Ipswich.

" IN the ſpring 1782, an old lay near Ipſwich was ploughed; the firſt plough ſkinned off the turf about an inch and half deep; women followed and laid the Potatoe ſets (the *Globe-white*, called alſo the *Champion*) in that furrow; then came another plough that cut as deep as poſſible, covering the ſets nine inches deep. There is no danger of burying them as they riſe freely. In this manner, without any manuring, planted every third or fourth furrow; part one, and part the other: in the firſt, the rows were 27 inches aſunder; in the latter, three feet. The former yielded the greater crop. They were all kept clean by horſe and hand-hoeing; were taken up with three-pronged forks, at the expence of a halfpenny a buſhel. The crop 400 buſhels an acre; and ſold at 2s. a buſhel, or 40l. an acre, gained at a very trifling expence.

"Not having any cluſter Potatoes of my own, I bought ſome of a neighbour, to try them in horſe-feeding, and from the reſult, prefer them to carrots. They were given raw, but waſhed, to ſaddle-horſes, each having a peck a day, and no oats whatever. The horſes were worked moderately, the ſame as on oats, did their work very well, and were in good order. At firſt they ſcoured, but it ſoon went off, and did no more than keep their bodies gently open.

"To aſcertain from this trial, the value of the Potatoes, that of oats will decide it; reckoning half a peck of oats a day to be equal feeding, and the price 16s. a quarter, the value of the Potatoes will be 1s. a buſhel.

TO MAKE YEAST FROM POTATOES.

BOIL Potatoes of the mealy ſort, till they are thoroughly ſoft, ſkin and maſh them very ſmooth, and put as much hot water as will make the maſh of the conſiſtency of common beer Yeaſt, but not thicker. Add to every pound of Potatoes two ounces of coarſe ſugar or treacle, and when juſt warm ſtir in for every pound of Potatoes two ſpoonfuls of Yeaſt, keep it warm till it has done fermenting, and in 24 hours it may be uſed. A pound of Potatoes will make near a quart of Yeaſt, and when made will keep three months. Lay your bread eight hours before you cake it. I have ſeveral times tried this receipt in a hard froſt when Yeaſt was ſcarce, and found it to anſwer the purpoſe ſo well, as not to be able to diſtinguiſh the bread made from the one or the other.

This, if practicable, is an invention of material conſequence to thoſe who bake and brew in their own houſes, and tends to ſhew the unlimited uſe of Potatoes.

SECT. XIV.

CARROTS AND THEIR CULTIVATION.

CARROTS are a root lately brought into uſe as food for cattle, and has been ſucceſsfully cultivated in the county of Suffolk and others adjoining. The following method of their management we preſent.

ON THE CULTURE OF CARROTS.

IN A LETTER TO THE BATH SOCIETY, BY JN. KIRBY, ESQ.

"I Have been favoured with your letter, enquiring after the method adopted in this county for the cultivation of Carrots; and ſhall think myſelf particularly happy if the intelligence I am enabled to communicate upon that ſubject, ſhould be thought worthy the attention of your very reſpectable ſociety, or in the leaſt degree tend to promote the good intentions of ſo laudable an inſtitution.

"The ſoil proper for the cultivation of this uſeful root is a ſandy loam, of about ſeven or eight ſhillings per acre; that on which I have uſually grown them is of a ſharper nature, and not ſo valuable. I have variouſly ſown them after turnips, ſummer-land barley, and peaſe ſet upon a rye-graſs ley; the crop upon the firſt has generally been moſt productive; next to that I ſhould prefer the latter. In the firſt inſtance we feed off the turnips by the beginning of February, and then lay the land up on ſmall balks or furrows, in which ſtate it remains until the ſecond week in March, when it his harrowed down, double-furrowed to the depth of about twelve inches, and the ſeed ſown thereon, at the rate of four pounds and an half to the acre. As ſoon as the plants appear diſtinctly, they are ſet out with a ſmall hoe, at the diſtance of ſix inches from each other; they are afterwards hoed twice more at different times, according as the crop ſeems to require it; and it is not unuſual to harrow them between the hoeings, which does no injury to the root, and frequently ſaves the expence of a third hoeing: for theſe three hoeings I commonly pay from fifteen to eighteen ſhillings per acre.

"When Carrots are intended to be ſown after peaſe, I uſually plough the ſtubble as ſoon as the harveſt is over, in order that the land may purge itſelf of weeds: in December it is laid up in ſmall balks to receive the benefit of the froſts; in February it is harrowed down, and manured at the rate of fifteen loads per acre; the manure is ploughed in to the depth of about four inches, and in the middle of March the land is double furrowed, and the ſeed ſown. By purſuing of this method, the manure lies in the centre of the ſoil, and not only affords nouriſhment and ſupport to the carrot in its perpendicular progreſs, but renders it eaſy to be turned up by a ſingle ploughing, and greatly promotes the growth of the ſucceeding crop of barley. With this crop I uſually lay down the land with rye-graſs, in which ſtate it remains for two years before it is again ploughed up, and ſometimes longer.

"The Carrots being fit to take up, I put them out to my labourers, ſometimes by the acre, and ſometimes by the load, containing forty buſhels; for the former, if a good crop, I pay for taking up and topping ten ſhillings and ſix-pence per acre; for the latter, from one ſhilling to one ſhilling and two-pence per load, taking particular care of the tops, which are equally valuable with the roots for cows, ſheep, and ſwine. After the Carrots are taken up, I lay them in an out-houſe, and cover them well with ſtraw, to guard them againſt the froſt, though it is not unuſual for ſome farmers to let them continue in the ground until they are wanted, which is leſs expenſive; and the weather muſt be extremely ſevere to injure the crown of the root, which is more hardy than either a turnip or potatoe. There is only one objection to which this practice appears to be liable, viz. that of the ground being ſometimes rendered too hard by the froſt to admit of their being taken up; but this may eaſily be obviated, by a little care and attention in the grower.

"Reſpecting the weight of an acre of Carrots, I confeſs my curioſity has not yet extended ſo far as to determine that point; but as to quantity, I uſually grow from 200 to 500 buſhels per acre, which we ſell at ſix-pence per buſhel.

JOHN KIRBY."

The ſoil on which Carrots grow to moſt advantage is a ſandy loam, of conſiderable depth, and to plant them on ſoil where they cannot ſtrike downward, for nouriſhment is throwing away labour and expenſe to little purpoſe. From the collected opinions of thoſe who have cultivated Carrots as food for cattle, they ſeem to poſſeſs more nutriment than any other root propagated for that purpoſe, particularly for horſes; that 40 buſhels will maintain ſix working horſes a week, allowing them hay, and that half the quantity of hay uſually given when horſes are fed on oats, will be ſufficient. Oxen are fed with Carrots quicker than with either turnips or potatoes; they increaſe milk in dairy cows, and contrary to cabbage or turnips, make butter ſweet and of a fine flavour: the quantity neceſſary for a cow that gives milk, is half a peck at night and the ſame in the morning; and with this quantity of Carrots, and good freſh ſtraw, they will be kept in better order, and produce more milk, ſuperior in goodneſs to cows fed with the beſt hay. Sheep are likewiſe very fond of Carrots, for which they are eſteemed a very wholeſome food.

SECT. XV.

MANGEL WURZEL AND OTHER ROOTS AND PLANTS NOT IN GENERAL CULTIVATION.

MANGEL Wurzel, or Root of Scarcity, firſt introduced into this kingdom, by Sir Richard Jebb, Bart. and preſented to the Society of Arts, from whom Dr. Lettſom obtained ſome of the ſeeds, and has cultivated them, according to his own account, to great advantage: and to whoſe induſtry we are indebted for the following information.

The ſeeds may be ſown as early in the ſpring as the weather will permit, on rich land well prepared, and tranſplanted from the ſeed bed, ſometimes in the month of May, on a loamy ſand, or rich hollow loam, at a diſtance of 16 or 20 inches from each other, at a depth of 4 or 5 inches.

At the end of June, or beginning of July, when the outward leaves are become about a foot long, the firſt crop of leaves is to be gathered, breaking them off near the root, which may be done at the end of every twelve or fifteen days, and are an excellent vegetable for the table, ſuperior to ſpinage.

ADVANTAGES RESULTING FROM THE CULTIVATION OF THE ROOT OF SCARCITY.

"THE numerous experiments that I have made, eſpecially in the year 1785, relative to the culture, the produce, and the uſe of the root of Scarcity, have convinced me, that it deſerves to obtain a decided preference over all other roots, and even over turnips. Whether I am partial, or enthuſiaſtick in my attachment to it, may be determined by conſidering the reaſons which I am now about to enumerate.

1. This vegetable may be eaten by men during the whole year: it is agreeable and wholeſome, and does not cauſe flatulencies, as turnips do.

2. As it is not attacked by the caterpillar, or by any other inſect, its ſucceſs is certain every where: it ſuffers nothing from the viciſſitude of the ſeaſons. Neither our own turnips, nor thoſe of England, poſſeſs theſe advantages.

3. The leaves of the root of Scarcity afford an excellent food for all kinds of cattle, during four months in the year; whilſt turnips produce leaves only once a year, and even then are tough, and injured by inſects.

4. The root of Scarcity may be well preſerved during eight months in the year, and is not ſubject to become rotten, as is the

caſe with turnips; which, from the end of the month of March, become ſtringy, tough, and ſpungy.

5. There is no kind of turnips which ever ſucceeds perfectly; they often fail entirely, eſpecially in hard lands; they require a light, good, and ſandy ſoil; but the Root of Scarcity will ſucceed every where; the cultivators of different kinds of lands may be equally aſſured of ſucceſs; and farmers and labourers may therefore be greatly benefited by this reſource.

6. The milk produced by cows who have been fed for ſome days together with turnips, contracts a ſtrong, ſour, and diſagreeable tallow-taſte; but thoſe, who are fed with the Root of Scarcity, produce both milk and butter of an excellent quality.

" The Root of Scarcity is never diſliked by cattle; they eat it always with the ſame avidity and the ſame pleaſure; and they have nothing to fear from thoſe unhappy accidents, which ſometimes reſult from the uſe of turnips.

" I ſhall eſteem myſelf happy, if the truths which I have ſtated ſhould encourage the cultivation of a Root, which may increaſe the riches of the ſtate, and contribute to the eaſe, and to the happineſs of the people.

" After having given the public every uſeful information in my power, reſpecting the Mangel Wurzel, or *Beta Hybrida*; and after having, at much labour and expence, diſtributed many millions of ſeeds, for the purpoſe of experiment, time muſt determine how far my endeavours, directed to the good of the community, will prove ſo eventually. It remains with me, however, publicly to thank my numerous correſpondents, among whom I may include many of the firſt in national rank, who have condeſcended to favour me with their approbation.

" To thoſe invectives, which ſome of the public prints have exhibited againſt me, I make no reply. However eſtimable the regard of virtuous characters may be, he will involve himſelf in diſappointment and remorſe, who acts merely, to gain the applauſe even of the good, or to deprecate the cenſure of the envious. If my conduct have acquired the former, my motives render me indifferent to the latter.

" I ſhould conclude this letter with regret, in being under the neceſſity of informing the public, that I am now exhauſted of all the ſeeds of the Mangel Wurzel which I raiſed myſelf, or procured from abroad, were it not in my power to add, that the ſeedſmen in London are now in poſſeſſion of a quantity to diſpoſe of.

" As I wiſh fully to appreciate the value of this vegetable, any future information reſpecting it will be acceptable to

" JOHN COAKLEY LETTSOM."

The worthy and reſpectable Dr. LETTSOM has beſtowed much trouble and expence in the cultivation and diſtribution of this plant, and doubtleſs from the pureſt philanthropic motives: his zeal has raiſed up a hoſt of illiberal and anonymous opponents, ſome to diſplay their wit, and others their ignorance; but all have failed in their attempts to hurt the feelings or character of ſo good a man. We cannot but think the Doctor too warm in his commendations of the Root of Scarcity, before he had ſufficiently made experiments; but we hope his ſanguine hopes will be gratified. As a further account of this *ſtranger*, which is ſo lately ſettled amongſt us, we give Sir THOMAS BEEVOR's, Bart. Letter to the Bath Society.

" MY ſeeds were ſent me very late, two months nearly after the moſt proper time of ſowing them; however, I ventured to commit them to the ground, on the 12th day of June laſt; and in a few days had the ſatisfaction to find them all riſe well, and in a vigorous ſtate of growth. I have ſince gathered their leaves twice, and find their roots of ſuch ſize as to promiſe a conſiderable and profitable production. The meaſure of ſome of them is now 15 inches round; the length (of a few I pulled up on this occaſion) is 13 inches, and the weight of them on an average 4℔. The ſeeds and plants are not, I think, to be diſtinguiſhed, at their firſt growth, from ſome beets; but in order to aſcertain the difference, (if ſuch there was) I ſowed on the ſame bed of mould, on the ſame day and hour, ſome ſeeds of the real beets; and find that, under the ſame management, the Roots of the Scarcity plant are four times as big, and the leaves of it much larger than thoſe of the real beets. I have offered a few of the leaves of the Scarcity plant to the cows whilſt going in exceeding good paſture in my park, which they readily ate; I did the ſame to ſome horſes which were ſtanding in a waggon in the harveſt field, who as readily ate the broad tender part of the leaves, but rejected the thick parts of the ſtalks. I have alſo had dreſſed the leaves of each of the above-mentioned plants, and brought boiled to my table; and think, as did ſome other gentlemen who ate of them, that there is a manifeſt difference in their taſte; thoſe of the Scarcity plant being ſo like ſpinage, as hardly to be diſtinguiſhed from it; whilſt thoſe of the beet were both harder and drier.

" What further obſervations I ſhall be able to make upon the growth and application of this plant, in the courſe of the winter, I will tranſmit to you, as it certainly promiſes to be of the firſt importance in the article of food for cattle. In the meanwhile let me not omit to inform you, that I ſaw a few weeks ago at Lord ORFORD's place at ERISWELL, near Barton-Mills, in Suffolk, ſome of the plants, which were nearly twice as big as mine: and I have been told, that at Mr. DASHWOOD's, of CLEY, in Norfolk, there are ſome which meaſure two feet in circumference; but the two laſt-mentioned parcels were, I am informed, ſown at leaſt ſix weeks ſooner than mine were."

JERUSALEM ARTICHOKES.

As all plants for agricultural purpoſes are valuable in proportion to the ſimplicity of their mode of cultivation, and their readineſs to grow on poor ſoils, the Jeruſalem Artichoke claims our attention; although it is at preſent a novelty in the farmer's Kalendar, it is probable, in a ſhort time, it may become uſeful and familiar. The following account of the cultivation and produce of the Jeruſalem Artichoke by N. BARTLEY, Eſq. near Briſtol, tranſmitted to the Bath Society, is the only one we have ſeen on ſo large a ſcale, and which does Mr. BARTLEY great credit as a friend to Agriculture.

At a conſiderable expence and trouble, I procured of theſe roots ſufficient to plant half an acre of ground, but I have them now in great plenty. I find the produce to be about 480 Wincheſter buſhels per acre; and I think they are about equal in value to potatoes for feeding ſtore pigs, ſuch as are not leſs than five or ſix months old. For fatting hogs, I do not find they are near ſo valuable as potatoes. But their chief recommendations are, the certainty of the crop, that they flouriſh in almoſt any ſoil, and do not require any manure, at leaſt for ſuch a produce as I have ſtated. They are proof againſt the ſevereſt froſt, and may be taken out of the ground as occaſion may ſerve. Whereas potatoes are ſoon affected with froſt, and muſt therefore be ſecured before the winter ſeaſon ſets in. I generally plant three or four acres in a ſeaſon.

Expences per acre, drills 3½ feet aſunder, ſets nine inches—time, beginning of March.

	£.	s.	d.
Rent	1	10	0
Two ploughings, at 5s.	0	10	0
Four ſacks of ſets, at 2s.	0	8	0
Flat hoeing	0	2	6
Farthing up twice, at 2s. 6d.	0	5	0
Digging 120 ſacks, at 3d.	0	10	0
	£. 4	5	6
PRODUCE.			
One hundred and twenty ſacks, at 2s.	£. 12	0	0
Deduct expences . . .	4	5	6
Profit .	£. 7	14	6

What is here adduced in favor of this plant will certainly ſtimulate thoſe who wiſh to improve Agriculture; to try experiments, we can only recommend them not to begin too expenſively. The time to plant Jeruſalem Artichokes is in March, or April, as you do potatoes, and the Michaelmas following they are at full growth.

CHICORIE SAUVAGE, OR WILD ENDIVE.

THE Chicore Sauvage is a plant very little known in England, but bids fair to become an acquiſition of great conſequence to the *rural œconomics* of this country. The Rev. Mr. COOKE, inventor of the well-known Patent Drilling Machine, has favoured Mr. C. Cooke, the publiſher of this work, with the following valuable information reſpecting the plant now under our conſideration.

" SIR,

" IN my tour through Normandy, Piccardy, and the Iſle of France, in October 1787, I had an eye to the reſpective Syſtems of Agriculture, as practiced in thoſe parts of the country, and was ſurprized to find the conſtruction of the implements in huſbandry, as well as the methods of cultivating the ſoil, rotation of crops, &c. &c. ſo much behind the common practical Syſtem of Agriculture in Great Britain. I think I could with ſafety pronounce them two hundred years behind us, both in theory and practice. I was alſo ſurprized, but very agreeably, at the ſight of ſeveral acres of land, covered with a ſucculent luxuriant herbage for cattle, of the plant called CHICORIE SAUVAGE, or Wild Endive, belonging to Mr. CRETE, of *Dugney*, near St. *Denis*, about 7 miles from *Paris*; eſpecially when I was informed, that upwards of forty tons, the produce of one ſeaſon, had been cut as green herbage for cattle, from one Engliſh acre, previous to my ſeeing it in the above flouriſhing ſtate in October.

" I was alſo informed, that the herbage of this plant, (which is perennial,) withſtood a moderate froſt in the beginning of winter, and that it begun to vegetate early in the ſpring. That this plant flouriſhed upon a dry, thirſty, gravelly ſoil, was ſelf-evident to me; it alſo ſtruck me very forcibly, that if this plant would flouriſh equally in our climate, the introduction of it might prove an acquiſition to this country. On which account, I was induced to requeſt of Mr. Crete, a little ſeed, which requeſt was very liberally complied with.

"This ſeed I brought to England, and diſtributed it in ſmall portions, to a number of my agricultural friends and correſpondents, ſuch as I apprehended would give it a fair trial upon different ſoils; and I have the ſatisfaction to ſay, that as far as I have ſeen of the cultivation of this plant upon a very ſmall ſcale, and heard of from others, its luxuriancy appears to equal, if not, ſurpaſs, that which I ſaw at Mr. Crete's; particular information of which I have already had from Wm. Whitmore, Eſq. of Dudmaſton, near Bridgenorth, in Shropſhire, from Mr. Crook, of Tytherton, near Chippenham, in Wiltſhire, and from Mr. May, of Perdis, near Ipſwich, in Suffolk. It is well known, that the ſoil of Mr. May's farm is a poor light unproductive ſand, not worth 4s. per acre; and if one half, nay, if a fourth part of Mr. Crete's produce can be obtained from the ſoils in this iſland, ſimilar to Mr. May's, the cultivation of this plant may be truly ſaid to be an acquiſition to this country, and worthy of every attention. In the preſent infant ſtate of the cultivation of this exotic, I have only to obſerve, that if it really begins to vegetate luxuriantly in the month of March, as I have been informed it does, the advantages to the farmer will be ineſtimable; in the time of ſcarcity of food for cattle, in the ſpring, when hay, turnips, cabbages, &c. are expended, and common graſſes not yet begun to vegetate, he will have a plentiful ſupply; in which caſe, the formidable month of April, and the beginning of May, will ceaſe to be any longer dreaded by the huſbandman.

"I have thus briefly communicated to you the information I have received of the plant called Chicorie Sauvage, in hopes of inducing cultivators of different ſoils to give it a fair trial.

Mr. C. Cooke, "And am,
Pater-noſter Row, "Your moſt humble ſervant,
Oct. 23, 1788. "JAMES COOKE."

The great ſervices this gentleman has already rendered the Agriculture of this kingdom, by his ingenious and uſeful inventions, are conſiderably increaſed by his introducing this promiſing and uſeful plant, and his making us the happy inſtruments of firſt communicating this acquiſition to the public, is a diſtinction we are not a little proud of. From the ſame ſource, we likewiſe learn the following particulars: That the proper time to ſow it is early in the ſpring broad-caſt with corn, as you do other graſs ſeeds, or plant it in rows with a drill, twelve or fifteen inches diſtant from each other; that broad-caſt, one buſhel and half is ſufficient to ſeed an acre, and drilled half the quantity. In France it may be cut as green food four times in a year, and all kinds of cattle eat it readily; it grows with a tap root, and ſtrikes a conſiderable depth into the earth; of courſe it ſhould be planted on a ſoil capable of giving it admiſſion.

Whatever tends to improve poor land is of the moſt material importance to Agriculture: of that deſcription the *Chicorie Sauvage* bids fair to ſtand foremoſt, and we make no doubt but in a few years its cultivation will become widely extended in this kingdom.

SECT. XVI.

HOPS AND THEIR CULTIVATION.

HOPS from their appearance in hedges, in a wild and uncultivated ſtate, are probably natives of this iſland; they naturally twine themſelves round whatever ſupport preſents itſelf, and without ſuch aſſiſtance will not flouriſh. It is ſomething remarkable that the Hop and ſcarlet kidney, or French beans, entwine round their ſupporters in oppoſite directions, notwithſtanding every effort to direct them contrary; we mention this as a curious phenomenon in natural hiſtory.

The uſe of Hops are abſolutely eſſential in England, as they conſtitute a very material part of the liquor which is the general drink of the inhabitants; this makes their cultivation very extenſive.

The Hop-planters buſineſs is very precarious, ſometimes the profits are immenſe, and at others, a great loſs for ſeveral ſucceſſive years; as an inſtance of the firſt, we have known a Worceſterſhire farmer make 1200l. profit from 20 acres of Hop ground in one year; the expence of tillage being very heavy, a failure of the crop for ſeveral ſucceſſive years occaſions a very great annual loſs.

Hops cannot be cultivated to advantage, except on ſtrong rich land of conſiderable depth of ſoil, which muſt be conſtantly manured, otherwiſe little advantage is to be expected. Land freſh broke up from paſture is preferable for Hops; if they are planted on ground, previouſly in tillage, it ſhould be as well cleaned, and in as high condition as it is poſſible to bring in by labour and manure.

Hops are planted early in ſpring, ſometimes in rows, of ſeven or eight feet diſtance from each other, the intervals of which are occaſionally ploughed, to pulverize the ſoil and deſtroy weeds, this cauſes the expence to be ſmaller; but planting them in hills is by all means to be recommended to thoſe who wiſh to cultivate them to advantage.

If you break up a paſture, the turf ſhould be firſt pared thinly off by a paring plow, and then followed and buried by the furrow-plow, at leaſt ten inches deep; if arable, the ridges on which the Hops are to be planted, ſhould be double plowed, or trenched with the ſpade; the latter method, though moſt expenſive, is certainly the beſt. This ſhould be done early in the winter, about which time the ground ſhould be marked out on which the hills are to be formed, and on theſe ſpaces a thin coat of well mellowed dung ſhould be laid to remain the winter. The vacant ſpaces have no need of dung, nor ſhould any be uſed but ſuch as is well rotted.

As ſoon after a hard froſt as the earth becomes dry and mellow, plow into a three-bout ridge the lands on which your ſetts are to be planted, leaving the intermediate ſpaces unplowed. But before this is done, meaſure out your ground and ſquare it, leaving the inequalities at the ſides or ends to be managed as hereafter directed. By ſquaring it, I do not mean that all the ſides ſhould be equal, only that they be ſtreight in order to add neatneſs and beauty to your plantation. The three-bout ridge ſhould meaſure four feet nearly, and by leaving an interval of ſeven feet in breadth, you will ſo manage, that your hills will all fall on the tops of the ridges, which will be of great advantage to your plants.

The ground being thus prepared and harrowed down ſmooth, your next care is to mark out your hills. The readieſt way of doing this, is, to have four painted ſticks about ſix or ſeven feet long; two of which ſhould be ſet upright with a plummet at each end, exactly at the diſtance you intend your alleys to be. Two men ſhould be employed in this operation, each with an eight feet ſtick (for that is the diſtance I would adviſe your hills to be placed) and a ſpade. Suppoſing the men to beat the oppoſite ends, they begin one from one pole, and the other from the other pole; and each directing his eye to the pole that is exactly oppoſite to that at which he began, with his ſtick and his ſpade he meaſures the ſpace from hill to hill, and throws up a ſpadeful of earth at each for a mark. In this manner both working alike, by meeting and croſſing one another, they arrive at oppoſite ends nearly at the ſame time; and then meaſuring and moving their poles, they proceed again in the ſame manner, and ſo continue to do till the whole plantation is marked. In forming your alleys eleven feet will be found a due proportion.

This operation completed, let them next begin to prepare the mould for the hills, which I would adviſe to be ſkimmed lightly from the ſurface of the intervals or once ploughed lands, taking that only which is perfectly fine, and gathering it into heaps; theſe ſhould lie juſt oppoſite the holes out of which the ſpadefuls were thrown, and thoſe ſpadefuls ſhould be turned up and laid upon the oppoſite ſides of the holes to where they lay when firſt thrown up. If froſt or ſnow ſhould intervene before the time of planting ſtir the mould again, and throw it up nearer to the place where the plants are to be ſet.

Thus every thing being in readineſs before the month of March, eſpecial care ſhould be taken to provide a ſufficient number of good ſetts, for which the younger planter muſt rely on the fidelity of ſome friend, as he cannot himſelf be a competent judge by any directions that can be given him on paper. The number of ſetts that will be neceſſary for an acre, according to the method here directed, is 2500, that is five plants to a hill, and about 500 hills to an acre: according, therefore, to the number of acres you intend to begin with, muſt be the number of plants you provide.

March, the proper month for planting, being come, the plants prepared, the ground moiſt, and the weather favourable, begin by filling up the marking holes, and juſt chopping the ground round them to looſen it, and then proceed to make up your hills with the fine mould already mentioned. This done, let the planter with his dibble make five holes in this manner : · : each about twelve inches a-part from the other, and rather inclining outwards towards the baſe of the hill than quite down-right, into which let him place his ſetts, which then will all point towards one another a-top, the uſe of which will more clearly appear hereafter; this done, let him with his hand hollow the hill like a diſh a-top, preſſing the earth cloſe to each plant with his dibble, and leaving the hole open for the reception of the firſt rain that falls. This done, let the two men proceed, one making up the hills, and the other planting till the whole plantation is completed.

Thus having completed your plantation, you have little elſe to do till the weeds begin to appear, and then inſtead of hoeing, dig up your once ploughed intervals, and throw the earth out equally on both ſides, ſo as to cover the ridge on which the Hops are planted, and ſmother the riſing weeds; this will add to the natural warmth of the ſoil, and help to enrich it; and when this is done, weed your hills, and, if the mould is fallen down, new dreſs them.

It is now the univerſal practice in Kent to pole the Hops, the firſt year with poles about 12 or 14 feet high. Theſe poles are either aſh, willow, poplar, maple, or aſp: the young planter muſt content himſelf with ſuch as the country he lives in affords; the poplar and willow are the ſooneſt raiſed; in Kent poles for the firſt year coſt about 10l. per thouſand; but poles twenty feet high for the ſucceeding years, ſometimes, coſt double. The common practice is polling as ſoon as the vines begin to riſe and bend; nature directs that they ſhould ſeek for help as ſoon as they begin to creep, and there ſeems to be a reciprocal attraction between the plant and pole, which it were in vain to attempt to explain, though daily experience confirms its exiſtence. This, however, will want the aſſiſtance of art to direct it properly, and the ſhoots muſt be led to the poles to which they ſeem moſt inclined, and lightly tied to them, to prevent their ſtraying. Three poles are uſually ſet to a hill; they are firmly fixed in the ground by means of an iron crow made for that purpoſe: the willow and poplar will frequently take root, if not well ſeaſoned before uſing, for which reaſon they are generally cut early in the winter, and expoſed to the air to harden, it not being found ſo proper to let them put forth leaves. In placing them they contrive to ſpread them a little a-top, as well for the convenience of air, as for preventing the vines from intermixing, which, without this precaution, they moſt certainly will do. No more than two vines are ever ſuffered to riſe upon a pole, the reſt are carefully trimmed from the ſtocks, and either uſed for raiſing new plantations or converted into dung. After the firſt year, however, I would adviſe the followers of theſe inſtructions to add one pole more to a hill, and let two vines approach every pole. The ground, managed as before directed, will nouriſh them, and by parting the poles properly at ſtaking them, they will want neither ſun or air to ripen them to perfection. Great care, however, is neceſſary, after poling, to watch the ſtraggling vines, to rectiſy the poles, and to replace whatever may by accident be thrown into diſorder. It is likewiſe uſual about Midſummer to top the vines upon the poles, that is, to pinch off the buds, in order to check their upright growth, and to promote their branching. This is done by means of a ſtay ladder, ſuch as gardeners uſe to cut trees.

Hop grounds ſhould be always kept clean from weeds, and the earth in fine tillage; to fix ſtated periods for labour to be performed would be impoſſible, and he who does not know when ſoil ſtands in need of ploughing or digging is unfit to be a farmer. About the beginning of Auguſt Hops are in bloſſom, after that the leafy ſubſtance forms itſelf, which is called the Hop. The general ſymptoms of their ripening are, a change of colour from a pale green to a yellowiſh hue, after this they ſmell fragrant and ſtrong, and the ſeeds will on examination be turned brown and begin to ripen; the ſmall leaves which compoſe the Hop ſeparate and open; this is a ſure criterion that the crop is fit to gather, which ſhould be immediately attended to, as delays are dangerous.

The methods of picking varies in different counties in England; in Kent they are picked in baſkets at a certain price per meaſure. In Worceſter and Herefordſhire they gatherers work at a price per day and their maintenance.

A ſpace is formed in the Hop ground, and a moveable article, called a crib, conſtructed ſomething reſembling in ſhape a hamper or crate, ſuch as glaſs is uſually packed in, but a great deal larger; this being fixed, the inſide covered with a cloth, it is the buſineſs of a man to cut the Hop wires near the ground, pull up the polls, and bring them with the wires upon them to the crib; the pickers ſtanding all round pull off the Hops into the cloth before deſeribed, which when full is carried to the kiln to be dried, and another put in its place for the like purpoſe.

Hops are dried on kilns built for the purpoſe, and muſt be carefully attended during the drying, particularly that the fire is not too ſtrong, and that they are duly turned.

Hops are dried with coal made into charcoal, generally called coke.

After Hops are dried, they ſhould be laid together in a room to cool; if they are baged hot from the kiln, the operation of baging reduces them to powder.

SECT. XVIII.

FLAX AND HEMP, AND THEIR CULTIVATION.

FLAX is cultivated to great advantage on rich land, and all attempts to plant it on ſoil, not of that deſcription, ſeldom turn out profitable. The plant has a beautiful appearance, growing with a ſlender upright ſtalk, ſmall leaves, and a blue bloſſom; on a minute examination each flower appears to ſtand in a ſmall green cup, compoſed of five pointed leaves, the flower in like manner conſiſts of five leaves; the whole of which reſembles the ſhape of a bell.

Freſh broke up paſtures are frequently appropriated to the growth of Flax, and which it is neceſſary to pulverize and reduce very fine; a crop of beans, previouſly taken, are by no means improper, and ſerve to pay rent and labour.

The month of April is the proper time to ſow Flax, the ſoil being dry and in fine tillage; from two to three buſhels are uſually ſowed upon an acre: and drilled, a buſhel or 5 pecks; much depends upon the goodneſs of the ſeed: drilling in rows 10 or 12 inches diſtant is preferable.

Linſeed is eſteemed good when it is large, oily, heavy, and of a bright brown colour; to know whether it be oily, a few grains are thrown into a red hot fire ſhovel, and if they are good they crackle almoſt inſtantly, and blaze briſkly.

If it be ſufficiently heavy, it will ſink to the bottom of the water; and to judge whether it be new, a number of ſeeds exactly counted ſhould be ſown on the end of a hot bed, and notice taken whether they all grow or not.

Flax is valuable for the ſeed, as well as for the product of the ſtalk, which by a proceſs is converted to linen.

Flax ſeed is well known for making oil, and its uſe as food for cattle is equal, if not ſuperior, to any ſeed that grows: from a pint to a quart of linſeed infuſed in two quarts of water, and given daily to a feeding ox or cow, will bring them forward very expeditiouſly, and is much more nutritious than barley meal.

When the ſeed of Flax is ripe the ſtalk is paſt its perfection; it is therefore commonly pulled before the ſeeds become quite ripe, when the head begins to droop and change colour; this ſhould be particularly attended to: the future proceſs belongs to the manufacture of Flax.

HEMP.

Hemp, like flax, muſt be cultivated on rich land; its appearance, while growing, very much reſembles the common nettle, and the part manufactured for cloth, cordage, &c. inſtead of being incloſed in the middle of the ſtalk like flax, forms the outward covering or peeling.

Hemp is ſowed about the ſame time as directed for flax; ſowed, about three buſhels to the acre, and drilled in rows 12 or 14 inches diſtant, one buſhel, or one buſhel and an half to the acre: drilling is certainly the moſt eligible method, as, without the land is in fine tilth, it is by no means proper to plant hemp.

Particular care ſhould be taken to procure freſh, bright, and heavy ſeed, and it ſhould be planted ſhallow in the ſoil: it ſhould be carefully weeded, or if drilled, the intervals between the rows ſhould be hoed three or four times in the ſeaſon.

Hemp is of different kinds, male and female, and ripens one before the other; the male firſt, which is known by the leaves changing colour and falling, and the ſtalk alſo becoming whitiſh. The female plant produces the ſeed, and ripens later than the male; which renders it proper management to pull them at different periods; this makes drilling more eſſential, as one ſpecies may be collected without injuring the other.

When pulled, care is taken to dry the ſtalks, which are generally tied in bundles.

Neither Hemp, or flax, will anſwer any profitable purpoſe, except on good land, which they very much exhauſt.

SECT. XVIII.

MADDER AND WOAD, AND THEIR CULTIVATION.

MADDER is a plant cultivated for its root, which is uſed by dyers; ſome ſmall quantity is alſo ſold as a drug. It appears an inſignificant running plant; the root being the object, the ſoil ſhould be rich, and deep, by no means of a ſtiff, clayey nature.

The ſoil on which Madder is intended to be planted ſhould be ploughed deep, and laid perfectly dry in autumn; and after ſufficient ſpring ploughing and harrowing, the time to plant it is in April: the ſets are procured from an old plantation, and taken off when they are about two inches above the ſurface; they ſhould be ſlipped from the plant at as great a depth as you can, as they will then have the better chance to grow; and as ſoon as they are taken off, it is proper to throw them into water to keep them freſh.

The method of planting them, as generally practiſed, is in equi-diſtant rows, two feet four inches diſtant from each other: women or children drop the ſets, and men immediately follow after and depoſit them in the earth.

If planted in the month of April there is little danger of their growing, eſpecially if the land is well prepared, and watering them will ſeldom be found neceſſary.

Great care is to be taken in weeding and hoeing, both to keep down the weeds, and pulverize the ſoil.

The root is not to be taken up for ſale till the autumn after planting, twelve months; as before that time they are not grown of a ſufficient ſize.

When the roots are taken up, they ſhould be gently dried upon a kiln, or other place adapted for the purpoſe; after which they are marketable. The intervals between the rows are planted the next year, and managed in the ſame manner as the preceding.

WOAD

WOAD.

Woad is a plant uſed by dyers, the leaves of which are valuable, and in colour are of a blueiſh green: a rich dry ſoil ſuits it, and on no other ſhould it be planted: the roots likewiſe ſtrike deep, and ſhould be accommodated with a ſufficient depth of good ſoil.

All thoſe plants which require a fertile ſoil, require alſo much ploughing and harrowing to prepare the land before ſeed time.

Woad is ſometimes ſowed in February or March; but the moſt proper ſeaſon is Auguſt: four quarts will ſow an acre broad-caſt, and drilled, half the quantity.

When the plants are two or three inches high, they ſhould be hoed from weeds, and left ſtanding about one foot diſtance from each other, and ſo remain during the winter, except the crop was drilled, in which caſe horſe-hoeing may be performed.

When the leaves take their firſt ſhoot in ſpring, the intervals between each plant ſhould be well cleaned, and ſtirred as much as poſſible, as it will cauſe them to ſhoot more vigorouſly.

The leaves of Woad are gathered when they are full grown, and continued from time to time during the ſummer, picking thoſe leaves only which are plump and juicy, and of a fine ſage green colour. As ſoon as they are gathered they are ſent to the mill, which is a branch of the manufactory.

Keeping the earth mellow by frequent hoeings greatly aſſiſts the growth of this plant, as well in its quality as quantity.

SECT. XIX.

MEADOW AND PASTURE, OVERFLOWING, DRAINING, AND CLEANSING DITTO.

MEADOW and Paſture are generally applied as ſynonimous terms, and, in ſome reſpects, they are ſo. All kinds of Meadow land may, with the greateſt propriety, be called Paſture, but all kinds of Paſture cannot, with equal propriety, be deemed Meadow.

By Meadow, we mean ſuch graſs land as lies level, or nearly ſo, and on which the traces, or appearance of the plough, are not viſible.

Paſture is graſs land ſituate on the ſides or tops of hills, and in vallies, always appropriated either to the purpoſes of growing hay, or depaſturing cattle; but which bear evident marks of cultivation.

Theſe we conceive to be the definite meanings of Meadow and Paſture, by which it muſt be underſtood, that Meadow, by being converted to tillage, and afterwards laid down graſs, becomes Paſture; but Paſture cannot be re-inſtated in its priſtine condition of Meadow.

This we muſt confeſs ſavours ſomething of ſylogiſtic argument, not tending to eſtabliſh any uſeful criterion by which the huſbandman can be benefited; but having made uſe of the terms Meadow and Paſture, we could not delineate the ſubject without making ſome remarks upon the outlines.

Meadow land frequently lies contiguous to rivers or brooks, and is liable, in wet ſeaſons, or by art, to be overflowed: this Mr. Young, and ſeveral of his correſpondents, calls irrigation, the word being of a curious dictionary conſtruction, and as Mr. Young, and ſome of his facetious correſpondents, laugh at the farmers when they are "puzzled and ſcratch their heads." we mention this for the benefit of thoſe who may not have had an opportunity of conſulting Dr. JOHNSON, previous to their attending the *Agricultural Society*, or the *Farmers Club*: for our parts we ſhall content ourſelves with uſing the familiar appellations of flooding, overflowing, or watering.

As the watering of Meadow and Paſture land is of the utmoſt importance to Agriculture, the improvement being generally great, and the expence often trivial, we here preſent our readers with certain abſtracts tranſmitted to the Bath Society, which cannot fail of inſtructing thoſe who attentively peruſe them.

"That water running from a ſpring, or out of a rock, is often preferred to water from a river that has paſſed ſome way. I apprehend, however, that this is not always the caſe; but ſometimes quite the reverſe. Springs coming immediately from a rock, or from the earth, are, I apprehend, of very different qualities. A ſpring coming from a lime-ſtone rock, I ſhould think by much the beſt for watering meadows, which is the caſe at Orcheſton in Wilts, where that famous graſs grows, which produces an amazing crop in thoſe ſeaſons when the meadow can be watered with the ſprings guſhing out of the lime-ſtone rocks. At other times, when the ſprings are low, the land does not produce more than a third of the quantity.

"It is underſtood by the farmers here, that water is very much impoveriſhed by watering a great many meadows on the ſame ſtream; and that thoſe meadows at the head of the ſtream are much the beſt on that account, except where there are a great number of farm-yards draining into it; which, in my opinion, makes up in part at leaſt for the deficiency.

"Water ſeldom, if ever, promotes vegetation, unleſs it be in a mixed or hetorogenious ſtate. It is therefore neceſſary, previous to the flooding of Meadows, to examine of what nature and quality your water is. All water that paſſes through beds or veins of minerals, or which contain calcarious nitre, copperas, allum, &c. is highly prejudicial to graſs lands. But water that iſſues from chalk cliffs, or lime-ſtone rocks, or ſand and gravel, is in general friendly. The beſt teſt is its ſoftneſs, which may eaſily be known.

"The quantity of water that is let over the land ſhould be in proportion to the nature of the ſoil, and the heat of the ſeaſon. If the ſoil be ſandy, gravelly, or chalky, and the declivity conſidcrable, the more water is wanted, and it ſhould remain the longer, eſpecially if the weather be warm, and it be a ſouth aſpect.

"If your water has run a long courſe above ground, the fouleſt is the beſt; but that coming immediately from chalk or lime rocks is warmeſt, and much to be preferred to foul muddy water in general. I muſt however obſerve, that water in a ſtate of putrefaction is poiſon to vegetables, and therefore ought never to be uſed for this purpoſe.

"Water, when carried over meadow lands after heavy rains, depoſits a fertilizing ſediment, which enriches the ſoil, and turns the mould blackiſh. It alſo promotes the ſpeedy putrefaction of every vegetable and animal ſubſtance found in the earth, and thereby contributes to the melioration of the ſoil under the ſward or turf.

"Care ſhould, however, be taken, that the quantity of water brought on the land be only enough to give vigour to the plants, without overcharging their veſſels. Never water your lands in very hot weather, for when the veſſels of the plants are filled, by the heat cauſing it to aſcend ſuddenly, a ſudden cold morning will greatly injure the herbage.

"If the ſpring proves dry, paſtures may be watered as ſoon as the froſty ſeaſon is over. But if the winter has been ſevere, and the earth remains moiſt, no current of water ſhould be admitted till the earth is ſettled, and the ſurface becomes dry; for the gentleſt ſtream would carry off the fine mould looſened by the froſt. After the graſs ſhoots, and the ſeaſon becomes mild, water ſparingly. In the ſummer never water but in great drought, nor even then, unleſs the water bc perfectly clear and ſweet; for muddy water would render the graſs foul, and give it a bad taſte.

"I conſulted my Meadow-floaters, who are unanimouſly of opinion, that the ſooner the water is thrown over the Meadows after it ariſes out of the ſprings, the more efficacious it will be.

"We have no ſprings on the hills in this part of the country, as in the neighbourhood of Bath; but our meads are full of them, and we apply the water iſſuing therefrom as ſoon as poſſible to the lands. We find ſpring water is better for this purpoſe than river water, on account of its being warmer in winter, and cooler in ſummer.

"I have a range of meads lying nearly on a level by the ſide of a little river, which runs near thirty miles before it reaches my lands. And in the upper part of my meadows a ſpring riſes of very clear ſoft water. Being deſirous of proving which would be moſt beneficial to the land, I have divers times, in different years, tried both.

"In a wet winter I can eaſily, at flood time, when the river is very foul and muddy, float all my meads by opening the bank by the river ſide. This I have done ſeveral times, and a great deal of ſediment has been left behind on the retiring of the water. In this caſe, I have generally had a large crop of graſs the ſucceeding ſummer, but I have always found it more rank, and the hay leſs ſweet, than at other times.

"When I have turned the water of my ſpring over the land, I have found the produce equally great, and the hay much finer and ſweeter than in the other inſtance. I have alſo obſerved, that thoſe meads which firſt received the water from the ſpring, were moſt luxuriant; and thoſe which it ran over laſt the leaſt ſo. I am therefore of opinion, that the beſt and moſt fertilizing water for Meadow land is that which iſſues immediately from warm ſoft ſprings.

"I formerly occupied ſome water-meadow not many miles diſtant from this place, where there is a great deal of land watered from the Kennet, a very conſiderable river which riſes at a village of that name not far from Marlborough. The occupiers of thoſe lands are uniformly of opinion, that the more thick, turbid, and feculent, the water is, the greater will be the benefit to be derived from the uſe of it: and the opinion is certainly well ſupported both by reaſon and experience. Haſty ſhowers, and very heavy rains, dilute the manure, and waſh away the fine pulverized earth from the adjacent lands for many miles round; ſo that as the waters increaſe, and become more rapid, they alſo become more replete with fertilizing matter, as is viſible to the eye by the quantity of ſcum, mud, and fine earth, remaining on the ſurface when the water is drawn off. The benefit derived from flooding may in general then be computed, *cæteris paribus*, from the quantity of feculent matter depoſited by the water, for it is, I believe, invariably found to be in proportion thereto.

"The effects of the water of land-ſprings muſt depend upon the nature of the ſtrata through which it paſſes, and may be beneficial or otherwiſe to vegetation, as that might be if applied in ſubſtance. Calcarious earths, in general, are friendly and conducive to vegetation; and from thence it ſeems probable, that water iſſuing from limeſtone rocks would promote the growth of vegetables in proportion to its impregnation by the calcarious matter.

"The effects of limeſtone water have never fallen within my obſervation; but from what I have obſerved of land ſprings, I have often thought the benefit from them was nothing more than from the ſimple fluid as a conſtituent part neceſſary to the accretion of all bodies, abſtracted from every principle of nutriment but what is contained in water as ſuch only.

"However, there cannot be a doubt, but different ſprings are impregnated with different qualities, the particulars of which cannot be known but from obſervations of their effects."

As the uſe of clear ſpring and river water, is greatly neglected by numbers who have it in their power to improve their paſture at an inconſiderable expence; the foregoing obſervations being the opinions of various ingenious gentlemen, will, we hope, be regarded with that attention ſuch rational ideas deſerve.

There is a material advantage in thoſe meadows which are liable to accidental overflowings, and thoſe which are capable of being overflowed at pleaſure, and are at all times out of danger. In the firſt the water may come at a wrong ſeaſon, and often does, to the entire loſs of a crop; but in the latter it never can come, but when the huſbandman thinks proper

Water running in a briſk manner over paſture in the winter, enriches it materially; but ſtanding water, which does not run off till diſperſed by the warm dry weather in the ſpring, does a great injury.

The methods of over flooding, practiſed in Gloceſterſhire and Wiltſhire, are very curious; large flood gates, or wines, are erected on the rivers, and channels cut to introduce the water over the land, which are contrived in a manner capable of flooding or laying dry any part you think proper.

DRAINING.

The Draining of paſture is an improvement of great conſequence, and on lands which lie with a proper deſcent, is very eaſily effected; we mean by Draining, ſuch Drains as are covered; for digging a ditch and letting it remain uncovered is not a ſubject worth mentioning; nor does it deſerve to be ranked with improvements.

Hollow or under Draining is generally attended with a great expence, and if well performed the improvement is permanent; for this reaſon, it ſhould by no means be done at the expence of a tenant; indeed, no gentleman poſſeſſing a particle of generoſity, would permit his tenant to throw away his property on ſo uncertain and precarious a foundation. When a ſwampy, or boggy place, is ſituate in the midſt of a field, the cauſe may juſtly be attributed to a ſpring in the upper part of ſuch wet place; the firſt circumſtance to be conſidered is to fix on a place for the drain to empty itſelf; this being done, begin there, and work up to the ſpot you purpoſe Draining.

Springs uſually lie on a bed of clay, for which reaſon it will be neceſſary to dig the drain of ſufficient depth, which need no deſcription to a perſon in the leaſt converſant with the buſineſs. Various methods are uſed in conſtructing the Drains; wood tied up in ſmall bundles is ſometimes placed at the bottom of the Drain, ſometimes ſtones are thrown promiſcuouſly together at the bottom; it is to be obſerved, that in both thoſe methods the Drains are brought to a point at the bottom, the ſides forming an acute angle; in either of thoſe inſtances, when the wood or ſtones are placed at the bottom, the turf which was taken from the ſurface is placed upon them with the graſs downward. For further information, we inſert from Mr. Young's Annals, Vol. 3. p. 378, the following,

ON DRAINING.

By R. H. Clarke, Eſq. of Bridwell, near Cullompton, Devon.

"No branch of huſbandry is attended with greater ſucceſs, in ſoils naturally wet and ſubject to ſprings, than underground drains, which are called with us, French gutters; the uſual method of making them, is with ſtone, but where there is a ſcarcity of that material, alder poles are ſubſtituted; and where wood is ſcarce, that method alſo becomes expenſive. I have a farm ſubject to all three of the above inconveniencies, and my tenant was adviſed to the following mode, viz. when the line is marked out where the drain is to be cut (which muſt be directly through the ſpot where the ſpring riſes, and fully at the head of it) with a ſpade of 12 inches wide, take the turf carefully up in ſquares, with a conſiderable ſubſtance of earth to it, and lay it by on one ſide of the intended drain; then cut the drain of the ſame breadth, three feet deep; take the earth out clean, leaving the bottom ſmooth; then, with a ſpade three inches wide, cut a channel in the middle of the bottom part, ſix inches deeper; when that is done, lay the turf in flat, with the graſſy ſide downwards, that will have a bearing of four inches and a half on each ſide, and leave a clear Drain, of three inches by ſix, to carry off the water; then fill the Drain to the ſurface with the earth that remains, and at the mouth, or where it is deſigned to diſcharge the water, ſecure it with a few bricks or ſtones. You will pleaſe to obſerve, that the depth prevents their being injured from any ſuperficial preſſure, and the only objection I have ever heard made to the plan, is, that they may be liable to be choaked by the moles; but I believe they ſeldom or never work at that depth."

Of all hollow Draining, that done with ſtone is to be preferred where they can be obtained; but where ſtones are not to be procured without a conſiderable expence, black thorn or elm bundles are a good ſubſtitute; otherwiſe, the ſides of the Drain being made nearly perpendicular; when you reach the clay, dig a channel about 4 inches wide, and 6 or 7 deep, in the middle of the bottom of the Drain, and cover it with the turf which was taken from the ſurface, and put on one ſide for that purpoſe, obſerving to lay the graſs ſide downwards, then fill up the Drain as uſual.

CLEANING PASTURE.

Paſture ground, of an inferior quality, is ſubject to become moſſy, ſometimes to a degree which renders it of little value; various methods have been deviſed to deſtroy moſs on Paſture. Scarrifying it in ſpring with a ſtrong harrow made on purpoſe has been practiſed, and ſtrongly recommended; but we by no means think it conſiſtent; it is true, if a dreſſing of coal aſhes, lime compoſt, ſoapers aſhes, or other ſuitable manure, has been freſh laid on, harrowing with heavy harrows may be uſeful, but without manure it cannot.

Paring, burning, and ſpreading, the aſhes on greenſward, overrun with moſs, is good management; but particular care ſhould be taken to pare the turf extremely thin, otherwiſe the Paſture is a long time before it recovers itſelf.

A ſlight dreſſing of mud, or loamy mould, is very ſerviceable to ſpread over the land at the time you ſpread the aſhes; they ſhould be well harrowed on with a thorn buſh, loaded with ſtones or a harrow with ſhort tines or teeth. The proper time to pare and burn moſſy, and coarſe greenſward, is as early in the ſpring as poſſible.

Cleaning Paſture ground from anthills, is certainly good huſbandry, although numbers object to the practice, and will tell you they know the injury attendant on the ſyſtem from experience; and with them we readily agree, provided the buſineſs is badly managed. We have ſeen great benefit from digging away anthills, in the following manner: As ſoon in autumn, as you can poſſibly ſpare time, dig up the anthills rather deeper than the ſurrounding ſurface, and having a cart ready, throw them into it, and immediately carry them off to a convenient place to make the compoſt heap; as ſoon as poſſible after, get if you can about one load of lime freſh from the kiln, to every five loads of the anthills, and mix it well together; if it has been properly mixed, the compoſt will be in condition to ſpread in the land the next ſpring; by this means the inſects will be all killed, and the land will be benefited.

If lime cannot be procured, ſoot, ſoapers aſhes, or animal manure, ſhould ſupply the place, obſerving to throw ſome of the compoſt on the bare places which were made by removing the hillocks. The ground ſhould be harrowed as ſoon as the dreſſing, which was put on, is in a condition to break to pieces in a proper manner.

SECT. XX.

HAY AND ITS MANAGEMENT.

The making and management of Hay has been learnedly diſcuſſed by many able theoriſts, ſome of them, in order to preſerve its virtues, diſapprove of expoſing it to the ſun; and we rather wonder that we have never ſeen it recommended in print to the farmer, to take his Hay home and dry it in the chimney corner.

The Editors of the Scotch Encyclopædia ſay, the beſt method of haymaking ſeems to be that recommended by their own countrymen, Dr. Anderson, as follows:

"Let the Hay-makers follow the mowers, and make the graſs
"into cocks about three feet high, giving each of them a ſlight
"kind of thatching, by drawing a few handfuls of the Hay from
"the bottom, laying them lightly upon the top, with the ends
"hanging downwards."

Had the learned Doctor and the Editors of the Encyclopædia been Iriſhmen, the reader would have laughingly called this method of Hay-making a bull; but as thoſe gentlemen are natives of a country, whoſe inhabitants are famous for their ſcientific learning, and accurate mode of expreſſing themſelves, we muſt content ourſelves with charitably ſuppoſing the Doctor meant to give a receipt for making dung inſtead of Hay, and hope no one will be credulous enough to try the experiment.

Hay made from clover, ſaintfoin, or other graſſes of the ſame kind, ſhould be treated in a different manner from natural or meadow graſs; but to preclude it from the influence of the ſun, is not the proper method to make good Hay.

The firſt object is the proper ſeaſon to mow graſs for the purpoſe of making Hay, and when that period arrives depends more on the practical judgment of the farmer, than any theoretic deſcription can convey.

Graſſes of all kinds are in their higheſt perfection juſt before they bloſſom, and that is the criſis which ſhould be the huſbandman's guide in mowing; a perſon who has a great deal of buſineſs, which will neceſſarily take up three weeks or a month, be the weather ever ſo fine, ſhould begin that he intends to mow firſt earlier than we have directed.

Graſs grown old in the field is of little more nouriſhment to cattle than ſtraw; and the land is materially exhauſted by bearing the crop till its virtues are evaporated.

From cutting graſs of all ſorts early, every advantage which can accrue, from good Hay, ſtrong and luxuriant aftermath, the ſoil not impoveriſhed, and every other good circumſtance that can be wiſhed, may be expected.

With reſpect to the making of Hay, graſs cut young and with its juices in perfection, requires much more making than that which is overgrown before it is mowed.

Saintfoin, clover, and other artificial graſſes of the like kind, ſhould be once turned in the ſwarth, and as ſoon as poſſible made into very ſmall cocks, the ſmaller the better, and from time to time turned till they are fit to be put together in rows for the purpoſe of carting to the ſtack or rick.

Natural meadow and paſture graſs being mowed in its proper ſeaſon, ſhould be ſpread in the morning, and before the evening raked in ſmall rows, and thoſe rows made into ſmall cocks: they cannot be made too ſmall, provided they are put together in a round ſnug manner: on the morrow the cocks ſhould be throwed and ſpread in rows, and turned and raked together as may ſeem neceſſary, and in the evening made into larger cocks than thoſe the preceding day: thus the proceſs ſhould be continued till the Hay becomes fit to carry together, which may be known by its handling light; and on twiſting a ſmall whiſp as hard as you can with both hands, obſerve that no moiſture appears, or the Hay is not ſufficiently dry to put together in a rick.

It is a cuſtom to make Hay into ſmall ſtacks of about a ton each, and letting them ſtand in that condition till the field, or the quantity deſigned to make the rick, is made ready, and then the rick or ſtack is made without intermiſſion. This prevents Hay heating immoderately, and, judiciouſly conducted, anſwers many convenient and good purpoſes.

SECT. XXI.

DIVIDING AND INCLOSING, WITH THE MANAGEMENT OF FENCES.

DRAINING and Incloſing, with the planting and management of Fences, being circumſtances of the moſt important conſequence to the flouriſhing and improved ſtate of Agriculture in this kingdom, and conſequently require to be treated rather at large; and as this ſection does not immediately come under Practical Agriculture, or the buſineſs of a tenant, we refer our readers to the article INCLOSURE, where they will meet with the theory and practice of one of the beſt informed men of the age.

SECT. XXII.

HORSES AND OXEN AS USED FOR HUSBANDRY.

ARthur Young, Eſq. has collected, from various quarters, the expence of keeping horſes for the purpoſes of Agriculture, and, on an average, finds about 16l. the expence of keeping a farmer's horſe one year, half the year in the ſtable with hay and corn, and the other half with green food, or turned to graſs.

Theſe calculations, or accounts, which may be ſeen in the Annals of Agriculture, vol. IV. p. 124, not meeting with the ideas and practice of Mr. WILLIAM PITT, of Pendeford in Staffordſhire, he writes the following on the ſubject, Vol. IV. page 423, Annals, &c.

ON THE EXPENCE OF KEEPING HORSES, AND COMPARISON OF HORSES AND OXEN,

By MR. PITT.

SIR,

"I make the following remarks on your expence of keeping horſes, alſo on the compariſon betwixt horſes and oxen, which if you think worth attention, may ſerve to fill a corner of your Annals.

"Firſt, it appears to me that you charge the full market price for hay conſumed at home, which is not fair: hay, if even fold to be conſumed on the farm, by no means deſerves the ſame price, as if carried clean off; the dung of cattle, or horſes, which eat ſuch hay, and the manure raiſed thereby, is a very material object: it is not eaſy to find data from which to calculate this difference of value; but from ſeveral correſponding circumſtances I conjecture, that Hay conſumed at home ought not to be charged at more than half the price of hay delivered at market; more eſpecially if carriage out be taken into the account; if this point be admitted, it makes a very conſiderable deduction from your eſtimate.

"Upon the average of nine years the value of Hay conſumed per horſe in your eſtimate is 6l. 2s. if one half be taken off for the advantage of home conſumption, it makes a deduction per horſe per annum of 3l. 1s. for Hay only.

"Secondly, allowance of oats being ſo various, is a proof at leaſt, that leſs than the largeſt allowance will ſuffice: I find the average (beans included) equal to 23 quarters per annum for four horſes, or 46 buſhels each horſe, and average price 2s. 3d. per buſhel.

"I have converſed with ſome very liberal horſe-keepers, who allow three quarters of a peck per day each horſe, when they bait at noon, and go out again at ſix at night; two quarters per day when they go out but once, and lay in the ſtable at nights; and one quarter per day at graſs: ſuppoſing theſe intervals of equal length, each one third of a year, it gives 45 buſhels and an half each horſe per annum, which very nearly equals your average. I allow leſs, viz. one buſhel per horſe per week in ſpring and autumn feed time; half a buſhel per horſe per week at other times, when they lay in the ſtable; and only half the latter quantity at graſs, but always mixed with plenty of chaff, or cut ſtraw; the above intervals are 16 weeks, 16 weeks and 20 weeks reſpectively, which makes only 29 buſhels per annum each horſe.

"Upon the other articles of expence I remark as follows: chaff cutting charged 1d. per buſhel, the price here, a half-penny and beer; ſhoeing very high, the average being double the price of this country; a common price here for ſhoeing huſbandry horſes is 7s. 6d. and 8s. per head per annum; I paid for ſeveral years 9s. per head per annum, on account of working them cloſer than other people; I am in doubt whether wheat-chaff ought to be charged, as being in few places a marketable article; and the extreme ill luck in 1768 is ſuch as I think ought not to join the general account.

"The following is the calculation of the expence of keeping eight horſes, upon an average of the laſt three years; which have generally been healthy, and equal to their buſineſs:

16 acres of clover mown for hay, at 1l. 15s. per acre, the rent of land and tythes being the half, viz. 17s. 6d. per acre	£. 28	0	0
Oats 240 buſhels, at 2s.	24	0	0
20 weeks ſummer food, from the beginning of June to about the middle of October, at 1s. 6d. per horſe per week	12	0	0
Shoeing 9s. per head	3	12	0
Decline of value at 1l. per horſe per annum	8	0	0
	75	12	0

"Chaff and farrier may bring it up to 10l. a Horſe per annum; and I am of opinion, that by œconomy and good management, Horſes for Agriculture buſineſs may be, and are kept in many places fit for conſtant work, without exceeding that ſum, upon the general average of many years.

"A breeding mare in a team of 7 or 8, may and does frequently prevent decline of value from being at all felt.

"The ſuperiority, or even equality of Oxen to Horſes, is, I think, by no means aſcertained; Oxen were half a century ago, much more in uſe in this country than at preſent. As an improved agriculture, and more extenſive cultivation took place, they by degrees gave way to Horſes; I have no doubt but Horſes thus gradually eſtabliſhed themſelves in conſequence of a decided ſuperiority, both with reſpect to docility and diſpatch; and be it ever remembered, that Oxen are by no means capable of thoſe quick exertions, ſo naturally and advantageouſly made by Horſes in critical times of ſowing and harveſt.

"Seven draught Horſes I look upon as a very complete ſet; they keep on three carts in carrying either dung or marl; they make occaſionally a waggon team and a plough team; are ſufficient for two plough teams in the ſtrongeſt work, and will occaſionally make three in barley or turnip feed time, or keep on a plough and two pair of harrows for ſowing at the ſame time; this number will do a vaſt deal of work, and will never want more attendance than a man and two boys, whoſe wages ſhall not exceed five ſhillings per week and board; I am perſuaded the ſame work cannot be done by any number of Oxen whatever, with the ſame attendance; nor probably without an extra man, whoſe wages and board will in its turn, "prove a moſt heavy burden," in a caſe where, by the uſe of Horſes, it might have been diſpenſed with.

"Again: upon wet ſoils and in wet ſeaſons, the treading of Oxen drawing the plough would be very injurious. What could have been done for more than a month, of rainy weather the preſent autumn, upon many wheat fallows, with four or ſix Oxen, when the ground would ſcarcely bear half the number of Horſes, notwithſtanding the advantage from the natural make of their hoofs, and ſmallneſs of number.

"I have never yet ſeen Oxen docile enough to be managed at the plough by one perſon; a holder and a driver, as far as I have obſerved, always attended them; on the contrary, three Horſes at a wheel plough require only a boy of twelve or fourteen, and will undoubtedly do more work."

"W. P."

As this gentleman, in his correſpondence with Mr. Young, ſeems to acquit himſelf in an ingenious and practical manner, we have given his letter at large, but do not in every reſpect agree with him.

The manure made from horſes kept in a ſtable, and well fed, is an object of great weight with a farmer who has it not in his power to purchaſe manure of equal value.

Horſes alſo are adapted for all kinds of buſineſs, in a manner that oxen are not: theſe circumſtances make it neceſſary that every farmer ſhould keep a team of Horſes; but thoſe who have a great deal of ploughing, and other buſineſs requiring either Horſes or Oxen, will greatly find it to their advantage to keep Oxen to perform part of the buſineſs.

Oxen are kept at much leſs expence than Horſes, are bought at half the value, ſubject to fewer accidents, and, properly managed, will do nearly as much work.

The cuſtom of drawing Oxen in the old method with bows and yokes is nearly exploded: the prevailing method at this time is to harneſs them as you do Horſes; the collar being cut open at one end in order to put it on their necks: Oxen uſed in this manner are of great ſervice to cultivators in general, and in particular to thoſe whoſe buſineſs for the plough is on a large ſcale.

We ſhall finiſh this ſubject with the following letter to the Bath Society, which does the writer the greateſt credit.

ON THE COMPARATIVE UTILITY OF OXEN AND HORSES IN HUSBANDRY.

"About five years ago, I took ſome land into my occupation, and having found the expence of Horſes very great, I determined, ſomewhat more than two years ago, to make trial of Oxen, and bought one pair. At that time, I am almoſt certain, there was not an Ox worked in this county; on which account my workmen added much to the trouble of breaking them, by their obſtinate prejudices againſt the uſe of them.

"At laſt I was fortunate enough to ſelect a labourer, who, though totally unuſed to them, was willing to take proper pains to break them. By his good treatment and temper, they ſoon became tractable, and as handy both at ploughing and carting as any Horſes.

"Being well ſatisfied with their performance, I reſolved to diſpoſe of all my draft Horſes, and ſubſtitute Oxen in their ſtead.

"I have now compleated my plan, and have not a ſingle cart-horſe; but the work of my farm (which conſiſts of upwards of one hundred acres of arable land, and ſixty of paſture and wood) is performed with eaſe by ſix Oxen; together with my ſtatute-duty on the high-ways, timber and corn, carting, harrowing, rolling, and every part of rural buſineſs. They are ſhoed conſtantly: their harneſs is exactly the ſame as that of Horſes, excepting the neceſſary alterations for difference of ſize and ſhape, they are drove with bridles, and bits in their mouths, and anſwer to the ſame words of the ploughman or carter as Horſes, and as readily. A ſingle man holds the plough, and drives a pair of Oxen with reins; they will regularly plough an acre of land, every day, and in leſs than eight hours time; I believe they will do it in ſeven, but I would not aſſert more than I know they perform.

"I have a ſmall plantation, in which the trees are planted in rows ten feet aſunder; the intervals are ploughed by a ſingle Ox with a light plough, and he is drove by the man who holds it. I mention this as an inſtance of their great docility.

"My Oxen go in a cart ſingle, or two, three, or more, in proportion to the load. Four Oxen will draw eighty buſhels of barley, or oats, in a waggon, with eaſe; and if they are good in their kind, will travel as faſt as Horſes with the ſame load.

"I frequently ſend out eighty buſhels of oats with only three Oxen, and one ox with forty buſhels in a light cart, which I think of all others the beſt method of carriage. My workmen are now perfectly reconciled to the uſe of oxen; and the following reaſons determine me to prefer them greatly to Horſes:

"1ſt. They are kept at much leſs expence. Mine never eat corn or meal of any ſort. During the winter, they are kept in good order for work upon ſtraw, with turnips, carrots, or cabbages; for want of either of the three latter, I allow one peck of bran a day to each Ox, whilſt in conſtant work. When my ſtraw is finiſhed, and the ſpring advances, they eat hay; and if they work harder than common in the ſeed time, they have bran beſide. When the vetches are fit to mow and give them in the ſtable, they have nothing elſe. After the day's work in the ſummer, they have a ſmall bundle of hay to eat, and ſtand in the ſtable till they are cool, and are then turned into the paſture.

"I am of opinion, that the annual difference of expence in keeping a Horſe and an ox, each in condition for the ſame conſtant work, is at leaſt four pounds.

2dly. The value of a Horſe declines ever year after he is ſeven years old; and is ſcarcely any thing if he is blind, incurably lame, or very old. But if an Ox is in any of thoſe ſituations, he may be fatted, and ſold for much more than the firſt purchaſe; and will always fat ſooner after work than before.

3dly. They are not ſo liable to illneſs as Horſes. I have never had one indiſpoſed.

4thly. Horſes (eſpecially thoſe belonging to gentlemen) are frequently rode by ſervants without their maſter's knowledge, and often injured by it. Oxen are in no danger of this kind.

5thly. A general uſe of Oxen would make beef, and conſequently all other meat, more plentiful; which I think would be a national benefit.

"That it may not be thought, that a pair of Oxen will plough an acre of land in a day only upon a very light ſoil, I muſt add, that the greater part of my arable land is too heavy to grow turnips to advantage. When my lighter lands are in fine tilth, I make uſe of a double plough; a ſingle man holds it, and drives one pair of Oxen, and will plough two acres a day.

"I am well aware, that the method of working Oxen with a yoke ſpares a conſiderable expence in the article of harneſs; but they move ſo much more freely with collars, and can be uſed with ſo much more advantage ſingly by the latter method, I think it far preferable.

"After experience has inclined me to give the preference to Oxen, I will not omit in my account the only material inconvenience I have found in working them; which is, they are troubleſome in ſhoeing, at leaſt I have found them ſo in this county; and, I believe, chiefly becauſe my ſmith never ſhoed any before. I have them confined in a pound whilſt they are ſhoed, and a man attends the ſmith. However, I think this diſadvantage amply recompenſed by more material advantages; and can with great truth affirm, that the longer I have worked Oxen, the better I have been ſatisfied with them.

"With great reſpect, I am, Gentlemen,
"Your moſt obedient, ſervant,
"R. KEDINGTON."

With reſpect to the diſeaſes of Horſes, Oxen, and all other kinds of cattle, we refer the reader to the Syſtem of **Farriery**, where they will ſee the ſubject copiouſly and practically managed.

SECT. XXIII.

COWS AND DAIRY.

THIS ſection we have appropriated to the articles Cows and Dairy. By Cows we mean all of the ſpecies of the Cow kind; and with reſpect to Dairy, we intend to treat of it here no farther than we think it is connected with the labours of the field, conſidering the making of butter and cheeſe as an independent Syſtem. Therefore, to the article **Dairy** we refer our readers, aſſuring them, however high their expectation may be raiſed, they will not be diſappointed in peruſing a production the reſult of long and extenſive experience, to which the author's name is affixed.

Almoſt every county in this kingdom have their reſpective breeds of cattle, of that ſpecies called the Cow kind: the diſtinction is generally to be obſerved in the length or ſhape of the horn, except in one kind, which are without horns.

The juſt proportion and due ſymmetry of make, in horned cattle, is in truth confined to a few ſimple obſervations, which we ſhall attempt to deſcribe.

In the firſt place, a round, tight carcaſe, wide in the hips and ſtrait in the back, filled up level behind the ſhoulders, the neck long and fine without any protuberant ſkin underneath, or what is commonly called throaty, the horns long, ſmall and taper, bending downwards, the head fine and ſmooth, long and yet ſmall, legs ſhort, ſtanding wide and firm, the tail fixed neither too high or too low, but growing in a right line with the back bone, the ribs formed in a regular convexity, particularly that called by the graziers the firſt rib, but which in fact may with propriety be called the laſt, it being the hindmoſt.

This is an outline of what the curious in cattle call a good beaſt; and we by no means think ſuch a Bull or Cow undeſerving the appellation; at the ſame time we would wiſh to be underſtood that there are good beaſts which do not tally with the above deſcription; ſome with ſhort horns, and others without any, are qualified to rank with the greateſt favourites belonging to either the Leiceſterſhire Mr. **Bakewell**, or the Oxfordſhire Mr.

Fowler. Theſe celebrated breeders have carried the improvement of live ſtock to the greateſt perfection.

Mr. Bakewell, taking him for all kinds of cattle, ſtands highly exalted; his name is doubtleſs foremoſt on the liſt.

But with reſpect to Horned Cattle, we can venture to pronounce Mr. Fowler, of Little Rollright, in the county of Oxford, proprietor of the fineſt breeding ſtock of beaſt that are in the poſſeſſion of any individual in this kingdom: to effect this has been a work of time and great expence.

It has always been thought neceſſary to mix and change the breed of Cattle, at leaſt ſo far as related to blood or conſanguinity; but the gentlemen we have juſt noticed have ideas totally oppoſite to thoſe old-faſhioned prejudices: they without ſcruple permit the dam, or ſire, and its offspring, to breed together, holding it an invariable maxim, that a complete Bull, and a Cow equally ſo, ſtand the faireſt chance to propagate a perfect calf.

This has been the practice of thoſe we have been ſpeaking of for a number of years, and the reſult has anſwered their moſt ſanguine expectations.

With theſe celebrated improvers of live ſtock, two or three hundred guineas is not deemed an uncommon price for a Bull or a Ram: this is certainly improving at an immoderate expence, and tends to ſhew the world that there are *connoiſſeurs* and *virtuoſi* beſides thoſe who deal in pictures, medals, or other antient relics.

There is undoubtedly truth in the notion that an Ox or Cow will feed more readily and with leſs expence, when they are kind and pleaſant in their nature and touch, or handle with a mellow ſoftneſs: it is not the grazier only will be benefited by purchaſing cattle of this deſcription; but the butcher, and even the perſon who eats the beef, will receive every advantage that can be deſired.

In buying cattle either for the purpoſes of the Dairy, or oxen to work or feed, it is of material conſequence to purchaſe thoſe which bid fair to turn out uſeful; ſome ſorts may be more ſo than others; there is no particular kind but what are liable to objections in ſome reſpects: beaſt bred on a farm generally are more healthy, and are ſubject to fewer caſualties than thoſe of another kind brought from a different ſoil.

As the weaning or rearing of calves for the uſe of the Dairy, or other purpoſes, is a particular and expenſive branch of Huſbandry, we preſent the following letter to our readers, written by the illuſtrious **Duke of Northumberland**; alſo with Mr. Young's Obſervations. Annals, vol. I. p. 293.

METHOD OF REARING YOUNG CATTLE.

By his Grace the Duke of Northumberland.

SIR,

"I AM to acknowledge the receipt of your letter on the ſubject of rearing calves in a leſs expenſive manner than has hitherto been practiſed, and, in anſwer to it, I muſt deſire to acquaint you, that I have for ſome time entertained an idea that ſkimmed milk might be prepared with proper ingredients effectually to anſwer that purpoſe, at about a third of the expence of feeding calves with new milk; the articles to be added to the blue or ſkimmed milk, are treacle and the common linſeed-oil cake, ground very fine, almoſt to an impalpable powder, and the quantities ſo ſmall, that to make 32 gallons would coſt no more, excluſive of the milk, than about ſixpence. It mixes very readily, and almoſt intimately with the milk, making it more rich and mucilaginous, without giving it any diſagreeable taſte.

"I have ſent you the receipt for making the *linſeed-milk*, which may be varied at diſcretion; and, though I have not yet had much experience of its good effects, I am inclined to believe, that under your care and direction there is a very great probability of its ſucceſs; it will afford me great pleaſure, if the hint I have here given, ſhould be found any way uſeful in promoting your laudable wiſhes to ſerve the public; and be aſſured I ſhall find great ſatisfaction, on all occaſions, in teſtifying the great regard and eſteem, with which I am,

Sir,

Your moſt obedient,

And moſt humble ſervant,

NORTHUMBERLAND."

"Take one gallon of ſkimmed milk, and in about a pint of it add half an ounce of common treacle, ſtirring it until it is well mixed; then take one ounce of linſeed-oil-cake finely pulverized, and with the hand let it fall gradually, in very ſmall quantities, into the milk, ſtirring it in the mean time with a ſpoon or ladle, until it be thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made nearly warm as new milk when it is firſt taken from the cow, and in that ſtate it is fit for uſe.

"N. B. The quantity of the oil-cake powder may, from time to time, be increaſed as occaſion may require, and as the calf becomes inured to the flavour of it."

OBSERVATIONS,

By A. Young, Eſq.

"THERE are two objects in rearing calves, each of which is of the greateſt importance: *firſt*, to effect it without the aſſiſtance of any milk at all; and, *ſecond*, to improve ſkim-milk in ſuch a manner as to render it more nutritious, it being well known that there is a prodigious difference in the growth and thriving of the animal when fed with *new* or *ſkimmed* milk. The Society of Arts at London offered for ſome years premiums for the firſt of theſe objects, and rewarded an account from Mr. Budd, of Wandborough, in Surry: his method was to feed them with a gruel made of ground barley and oats, the particulars of which are to be ſeen in the third volume of *Doſſie's Memoirs of Agriculture.* On this method I ſhall only obſerve, that I followed it with the greateſt exactneſs laſt year with two calves, both of which, ſo far from being reared, were ſo reduced, that, though I changed their diet to milk upon finding it would not do, yet I was too late with the change, and they both died. I will not generally condemn the method from one experiment, but I muſt own, I have many doubts of its ever proving a *real* and entire ſubſtitution for milk.

"During my reſidence in Ireland, I had the opportunity of buying calves at three days old for the price of 20d. to 3s. which induced me to make many experiments in this enquiry. Knowing before I went, the cheapneſs of calves, I had collected various receipts for weaning them, among others hay-tea; bean-meal mixed with wheat-flour; barley and oats ground, nearly, but not exactly, in Mr. Budd's proportion; but principally flax-ſeed boiled to a jelly and mixed with warm water: this being recommended more than the reſt, I tried it on more calves. The reſult of the experiments on above thirty calves was regiſtered regularly, but the minutes loſt, with other papers, in packing up and moving from one kingdom to another: the general reſult, however, I well remember. In above thirty calves, I reared not above three or four, and I was convinced as ſtrongly as the experience of one ſeaſon could convince me, that none of the methods tried deſerved reliance. Barley and oat-meal, with a very ſmall quantity of flax-jelly, reared the few that eſcaped, except one, on which a trial was made at the ſuggeſtion of my coachman, who had reared many calves. He deſired to mix two-thirds ſkim-milk, and one-third water, with a ſmall addition of flax-jelly well diſſolved; that calf recovered quickly from the low condition it had been reduced to, and afterwards throve well.

"Upon the whole, I have no ſlight reaſon to think, that this firſt object remains nearly in as great ſtate of uncertainty as ever: I am far from pronouncing that it cannot be done, and intend multiplying my experiments in the enquiry as often as I am able; all I can aſſert is, that I have hitherto had no ſucceſs.

"I now come to the ſecond object, that of improving ſkim milk, a deſideratum as much to be deſired as the former.

"The moment I received the above very ſatisfactory communication from that great patron of every patriotic endeavour to ſerve the public, **the Duke of Northumberland**, I tried it exactly according to the receipt, and, at the ſame time, recommended to two farmers in different parts of the kingdom, who I knew were ſolicitous for diſcoveries of this kind. It anſwered with me as well as I could wiſh the firſt ſeaſon, and has ſtood a ſecond teſt; the farmers to whom I communicated, report alſo favourably of it: in all caſes it has appeared to do better than ſkim-milk alone. Thus one material point is gained; not the compleat eſtabliſhment of the method, which can only follow multiplied and varied experiments; but a proof that it may very ſafely be recommended to thoſe who are the moſt cautious, and the moſt fearful of incurring expence.

"Being able to declare thus much in its favour, I lately wrote to His Grace, informing him of the ſucceſs, and requeſting his permiſſion to publiſh it, which, by another letter conceived in the handſomeſt terms, he allows me to do. I can only add, that ſuch a liberality of ſentiment gives a luſtre to exalted rank; ſets an example of attention to the welfare of the loweſt claſſes; and connects greatneſs with its right baſis, THE PEOPLES GOOD.

A. Y."

Young calves are ſubject to various diſeaſes, which will be noticed under the word **Farriery**, as we have taken the liberty to claſs the diſeaſes of all domeſtic animals in different ſections under one head.

SECT. XXIV.

SHEEP.

SHEEP, like cattle of the neat kind, are of different ſorts, generally adapted in their ſize to the poverty or richneſs of the paſture on which they feed.

Small Sheep yield the beſt mutton and the beſt wool, but there are advantages which ariſe from a breed of large Sheep which makes the ſcale preponderate entirely in their favour.

AGRICULTURE.

On large extenſive commons the Sheep are generally ſmall, and of little value; on thoſe places Sheep are liable to a number of caſualties which thoſe in incloſures are eaſily defended from.

The great improvement which has been made in this kingdom in the breed of Sheep muſt be attributed to incloſures; by incloſing every perſon becomes independent of his neighbour, as far as reſpects his buſineſs, and if a ſpirit for improvement is his wiſh he can exerciſe his will uninterrupted.

A few years paſt a committee of tradeſmen of the City of London met to enquire into the cauſes of the high prices of proviſions, and to petition and requeſt parliament to paſs ſome act to redreſs the grievance.

This wiſe experienced committee attributed every thing to the numerous incloſures which had recently taken place; their Secretary, Mr. Deputy Leekey, was deſired to write to Arthur Young, Eſq. to procure his opinion, which Mr. Young very politely complied with; and as we think it does the greateſt credit to the author's heart and underſtanding, we preſent it to our readers as a maſter-piece of the kind; the high price of mutton being the principal thing complained of, it appears with propriety in this place.

ON THE HIGH PRICE OF PROVISIONS.

By Arthur Young, Eſq;

SIR,

"I HAVE attended for more than twenty years to various complaints in and out of parliament, which have been made on *high* prices of proviſions, as they have been called; but I never ſaw the leaſt good reſult from any ſuch meaſures, though ſeemingly no more than enquiries; and when laws have been made in conſequence, they have always done miſchief. There is no inconſiderable reaſon for believing that whatever *is* the price, *ought to be* the price; ſince price can be formed by nothing but quantity, demand, and competition. If quantity does not exiſt, nobody I ſuppoſe can expect cheapneſs. If demand does not exiſt, the farmers can never expect a good price; and if competition does not take place, trade cannot be free or the price fair. Now the only point on which laws or regulations can bear is the laſt, to prevent monopolies: but if by proviſions you mean bread and meat, a little reflection will prove how impoſſible monopolies are. What capital does it take to ſet up a butcher or a baker? at ready money prices an hundred pounds will do either. How then can profits riſe too high when competition ſo eaſily takes place! and when do you hear of enormous fortunes made by butchers and bakers? I am rather inclined to think them among the pooreſt of the claſſes; certainly the bakers; and when butchers are in good circumſtances, it ariſes generally from a very fair intereſt on ſome tolerably good capitals. The misfortune of theſe enquiries is, that if you miſtake the cauſe, and, inſtead of attributing it to want of quantity, think it owing to a want of competition, and in conſequence of that idea take meaſures to eſtabliſh it—— miſchief is ſure to reſult; of which we have formerly ſeen various inſtances in laws againſt foreſtallers, regraters, &c. all which raiſed prices inſtead of ſinking them. Perfect freedom of trade is the only means of ſecuring the neceſſary competition. If the corporation of London give certain privileges to a butchers' company —if there are laws that enforce long apprenticeſhips that are unneceſſary, whatever regulations you may have of this ſort among yourſelves, they all tend to reſtrain and regulate what ſhould be as free as air, and as far as ſuch regulations take place muſt certainly have ill effects; for there can be no doubt but all corporations and all companies are mounds raiſed againſt freedom of trade, and conſequently public nuiſances.

"But give me leave, Sir, to aſk what reaſon any perſon can have to expect cheap proviſions at preſent, if by that term *meat* is underſtood? Laſt winter, hay, ſtraw, and fodder of all kinds, were ſcarcer and dearer than ever known in this kingdom. Severe froſts deſtroyed the turnips; cattle of all kinds, and ſheep ſuffered dreadfully; many died, and the reſt were in ill plight to fatten early in this ſummer; would you, in ſuch a caſe, have had meat cheap? that is only aſking whether you would have thoſe farmers ſtarve, whoſe wealth alone can feed you; you might as well burn all the ploughs to make corn cheap.

"Such, Sir, are my ideas on the preſent enquiry; they call for no exertions, becauſe the leſs that is attempted the better; and *doing nothing*, in this caſe, as in many others, is the beſt policy.

I am,
Your obedient and devoted Servant,
ARTHUR YOUNG."

Sheep, which at this time go under the denomination of Leiceſterſhire Sheep, are unqueſtionably the moſt profitable of any breed that are known; they grow to a large ſize, and will live nearly as hard as ſome others which do not weigh more than two-thirds of their weight; if the fleece is not worth ſo much per pound, its weight makes it of three times the value; and the mutton which epicures think inferior, we will defy them to diſcover any difference, provided they do not ſee the ſize of the joint from whence it was taken. We think ourſelves juſtified in the prediction, that, in a few years, there will be ten Leiceſterſhire Sheep kept in this kingdom to one of any other kind.

The profits on a flock of ſheep have lately been a matter of contention between Mr. Macro, of Barrow, in Suffolk, a gentleman farmer, whoſe productions we have ſeveral times in the courſe of our Syſtem taken notice of, and are ſorry we cannot, on the preſent occaſion, the ſubject being taken up on ſo large a ſcale; and his Grace the Duke of Grafton. When a nobleman of ſuch political conſequence and poliſhed manners as the Duke of Grafton condeſcends to correſpond with a plain ſenſible Farmer, the public muſt anxiouſly wiſh to ſee the ſentiments of ſo high a character, on ſo humble a purſuit as that of Agriculture; we therefore lay the Duke's excellent letter before the public.

ACCOUNT OF A FLOCK OF SHEEP.

By His Grace the Duke of Grafton.

"The account, given by Mr. Macro, of his Flock of Sheep, is, as you obſerve, ſo very complete on that point, that I have waited in expectation of ſeeing ſo good an example, (which has been given by my neighbour) taken up by others of intelligence and experience, and that we ſhould have been furniſhed with the means, before this time, of weighing, on juſt and ſatisfactory grounds, what are the benefits, or diſadvantages ariſing from Sheep, on each ſeparate kind of land, and to which particular breed of Sheep, the preference ought to be given in every different ſort of country.

"Though Mr. Macro has deſired that it may be obſerved, this account is confined to *his own* farm, to breeding from *ſtout* ewes, on *that* farm, *great* lambs; he, at the ſame time, has fairly intimated, that, on a farm, different in nature, and on land lower rented than his own, the advantage and profit may conſiderably increaſe; yet, notwithſtanding this candid and reaſonable declaration from him, many perſons, who, have either haſtily caſt their eyes over his account, or, who have heard it ſtill more indiſtinctly related by others, have run away with the notion, that Mr. Macro has proved, that no farmer could ever find his account in having a large flock, indeed any flock of Sheep; and that Sheep were unneceſſary in farming moſt lands, if neceſſary on any. As an article of the firſt neceſſity, and as a moſt beneficial one to the nation, as well as to individuals, in trade and manufactures, we are all concerned to prove the fallacy of ſuch an opinion. And here we may always rely on one excellent ſecurity againſt this and moſt other wild projects, which is, the private intereſts of individuals, among a people ſo active and induſtrious as we are; for, I will venture to anſwer, that the very attempt to lower the quantity of Sheep in the iſland, or even, that the expectation alone of ſuch a ſtep, would at once raiſe the price of the article, and quickly call back the grazier and farmer from ſuch a deſign. On the ſame ground of reaſoning, I have always made myſelf eaſy on the conſideration of the poſſible conſequences that might ariſe from the incloſure of ſo many common fields; conſequences, which, at firſt ſight, I acknowledge, were alarming, but, which experience has ſhewn to have been more frightful at a diſtance than they have proved to be ſo in the event. It may be depended upon, as a maxim, in Agriculture, as in trade, whenever any article becomes, by accident, or by the nature of it, to bear a higher price, that more induſtry will be uſed inſtantly to provide you with that commodity. Butter, corn, cattle, &c. all ſtand on the ſame ground, and, in proportion, as one gains upon the other, or becomes more ſought after, than the others, ſo will it be found, that more land will be turned to the produce of that article, which is moſt demanded.

"Theſe ideas alſo, relative to Sheep, I am ſatisfied, will ſpread but little; they can have no weight with thoſe who are informed: but ſtill, there are certain objects ſo neceſſary, and of ſuch conſequence to the community, that I am always ſorry to hear ſuch ſubjects looſely diſcuſſed; and I cannot think it politic or wiſe, ever to bring it in doubt, whether Sheep are, or are not, a beneficial part of farming. They underſtand Mr. Macro very ill, who draw this inference; ſo far from ſaying ſo, I am perſuaded, that, if the queſtion was put to him, he would readily anſwer, that, if he had even found the balance of the account much againſt him; yet, "he conſidered the advantage "the farm received from the flock was ſuch, that, on that very "farm, he could not go on, nor pay his rent, without his "Sheep, although he ſhould be a loſer by that article, taken "ſeparately." If ſo, they become upon *his* farm as neceſſary an article as any utenſil belonging to it.

"Another opinion, I underſtand, is, now much propagated, and it is, as I hear, with the authority of a gentleman, whoſe merits, as a breeder alone, call for the general thanks of the nation, beſides the good qualities, and knowledge, which render his character ſo reſpectable. This opinion is ſo readily and eaſily confuted, if wrong, that, I am not much alarmed for any bad conſequence that may happen from the notion, "that Sheep, "by being folded regularly, are of no more advantage, or leſs, "than if the ſame were on the grounds, or lands at liberty "without folding." I own that this poſition is, or may be more problematical than the other; and though I differ extremely in opinion from the gentleman alluded to, I would wiſh to refer any perſon to the moſt experienced, and who are the moſt thriving in their neighbourhoods, and to aſk fairly from ſuch farmers, whether they could have gained what they were poſſeſſed of, without having folded their Sheep on the lands, which were preparing for a crop; and to deſire them likewiſe to make enquiry within their reach, whether the moſt thrifty amongſt theſe farmers were not preciſely thoſe, who had the beſt opportunity of folding, and had practiſed it the moſt. If he ſhould receive for anſwer, contrary to my expectation, that ſuch farmer preferred other means, and had not followed this method; may I, without preſumption, ſay, that I conceive that ſuch an anſwer can only come from one, who has carried on farming near a capital town, or within reach of ſome adventitious manure; or elſe from one, who has farmed on a bargain, where the arable has borne no proportion to the paſture, or meadow; and where the ſtock fed upon the latter two produced all the manure he could want for his crops of grain? But, if the report of ſuch men as theſe ſhould ſtill not ſatisfy, I think, that it would be no difficult matter to prove the fallacy of ſuch an idea, by argument firſt, and if that failed, by fair experiment. However, ſir, my buſineſs at preſent only relates to the profit of a Flock of Sheep kept on a farm, differing in ſoil, &c. from Mr. Macro's; and confining myſelf to the account of this ſingle Flock, and that my own, I ſhall give it to you, to diſpoſe of as you may judge beſt, who thought that the communication might be of ſervice. I had been deferring from time to time, (on account of one avocation or another,) to make out an accurate account, *debtor* and *creditor*, of this flock; and I do not know, but the ſame cauſe might have kept me much longer, if your viſit to me, at Euſton, for a few days, had not rouſed me to undertake it. The materials were all at hand, and capable of being referred to, in the moſt accurate manner, as you know: the heat of the weather made in-door amuſements very deſirable, and I ſat down heartily to the buſineſs, which you will recollect took up a good part of one day, and ſeveral hours of the next; and, I can venture to deliver this as an accurate account: but, as this comprehended the laſt year alone, you were not ſatisfied, without following it through the ſix preceding ones, and from thence, ſtriking the balance of each article, on an average of ſeven years.

"It is a conſtant, and juſt remark, that the numerous publications, on the various branches of Agriculture, contribute but little to the improvement of that ſtudy; that few of the experiments, though delivered therein, almoſt under the colour of demonſtration, are brought into uſe, or common practice, to which end all ſuch writings ought to direct. To what is this to be imputed? though of theſe many may be given to the world, and certainly are, without ſufficient conſideration; yet among the number of writers, whoſe zeal calls them forth on theſe occaſions, there muſt alſo be many, who are very able, undoubtedly, to give the beſt leſſons on the ſubject they treat, and to juſtify them by experiments of their own. However, too often it happens, that the particular deſcription of the lands, and ſoil, as well as of the general nature of the farms on which theſe have been tried, are omitted; and this is ſo material a point, that no one muſt expect to be followed, without it: or elſe, the writer, captivated with his own ſucceſs on a ſingle ſpot, gives it to the kingdom in general, hoping to ſee it adopted, when, probably, it was calculated only for that ground on which the experiment was made, and might become of no uſe, if tried on the other ſide of the next hedge. Agriculture, I believe, admits of deciding rules leſs than any other purſuit; for almoſt each piece of land requires ſome one particular to itſelf. Let all experiments, and even precepts, be deſcribed as exactly as poſſible, with every dependent circumſtance; and then, I am perſuaded, the rational ones will never want curious perſons to give them a ſufficient and candid trial.

"In order that I may not fall into the ſame error, from which I have preſumed to warn others, I muſt ſtate, that my farm is chiefly on that ſort of ſandy ſoil, which is to be found in the neighbourhood of Thetford, and reſembles moſt of the farms thereabout, in the nature of the land, as well as in the Sheep walk and heath: in many or moſt parts of which, chalk lies at no great depth; and in a few ſpots a good loam appears, ſurrounded by theſe light ſands. The more valuable and fruitful parts have been made ſo at the expence of a thorough coat of clay, found in many places on it. Theſe lands, thus improved, are moſtly incloſed with good quicks, and admit of the three ſhift huſbandry; while the reſt is quite open, and lies four or five years, before it comes again under the plough. Beſides the turnips allotted to the Flock, as mentioned underneath, about ſixty or ſeventy acres more are grown annually for the fattening Scotch beaſts, and for the cows alſo at particular times. In making out this account, you know that we have delivered it, in the way that might correſpond as nearly as poſſible with the articles contained in that of Mr. Macro, and followed his method; thereby allowing every one to make the compariſon with leſs trouble to himſelf."

SECTION XXV.

PIGS.

PIGS, either wild or domeſtic, are animals more univerſally exiſting in all parts of the globe, than any other kind whatever, although ſo conſiderable a part of the inhabitants of the earth are, from religious motives, forbid taſting their fleſh. In our country they are in great eſtimation, as they yield the food on which huſbandmen chiefly ſubſiſt; they are very prolific in their nature, as a Sow generally produces from ſix to twelve Pigs at a litter.

The breed of Pigs have been greatly improved, both in the hardineſs of their nature, and the goodneſs of their fleſh, by the introduction of thoſe commonly called the Chineſe, or Tonquin, Pigs, thoſe being put to breed with the large long-legged, large eared-kind of our own country, have produced, in all reſpects, a great improvement. In various parts of the kingdom, young growing Pigs are put to feed on clover, during the ſpring and ſummer, a method very profitable, and deſerving of general practice; it ſhould be remembered a few beans or peas ſhould be given in the morning, to keep them healthy; but an inconſiderable quantity will be ſufficient.

As faithful recorded experiments are the only documents which can be confided in, and the feeding of Pigs the expenſive and material circumſtance which belongs to them, we tranſcribe the following from the Annals of Agriculture, vol. III. page 482.

EXPERIMENT ON FATTENING HOGS.

By Alexander Baxter, Esq.

"SIR,

HAVING been long deſirous to know, with preciſion, what profit ariſes from the fattening of Hogs, as a very eſſential branch that relates to the ſupport of man; I was very happy to find, in the firſt volume of the Annals of Agriculture, the account of a ſet of accurate and well-conducted experiments by Mr. Young, the worthy editor of that valuable publication.

From the example of ſo great a man, I was induced to follow out my idea, by making experiments on this ſubject occaſionally; and I have now the honour of producing before you, and this honourable ſociety, the following

Experiment in fattening four Hogs.

Nov. 24, 1784. Bought four Hogs of the Chineſe breed, mixed with the Engliſh, about nine or ten months old, for 5l. 5s.

Having been driven five miles, and faſted till next morning, they were weighed,

Hog, Nº	1	——	119½ lb.
——	2	——	112½
	3	——	109¼
	4	——	118¾
		Total	460 lb.

Which is very near 2¼d. per lb. alive at 5l. 5s.

Dec. 16. Weighed them in the morning faſting, having fatted juſt twenty days ſince laſt weighing.

		lb.	oz.
Nº. 1	weighed	162	14
2	——	154	0
3	——	146	0
4	——	160	6
		623	4

Nº.		lb.	oz.		lb.	oz.
So that 1	gained in 20 days	43	6	per day	2	$2\frac{14}{20}$
2	—	41	8	——	2	$1\frac{4}{20}$
3	—	36	12	——	1	$13\frac{8}{20}$
4	—	41	10	——	2	$1\frac{6}{20}$
Total gain in 20 days		163	4	per day	8	$2\frac{17}{20}$

And, one with another, each has gained per diem, 2 lb. ½oz.

During theſe twenty days, they have coſt

				£.	s.	d.
Nov.	24,	prime coſt, -	-	5	5	0
	25,	Expences -	-	0	0	11
	26,	Five buſhels grains	5d.	0	2	1
		One ditto beans	33s.	0	4	1½
		One ditto barley, ground	28	0	3	6
	29,	One ditto beans	33	0	4	1½
Dec.	1,	Three buſhels barley gr.	29	0	10	10½
	6,	One quarter ditto	29	1	9	0
		Total expences, at 6th December		7	19	7½

Which makes the price at this period, nearly 3d. per lb. live weight.

And if, as I find afterwards, the proportion of the dead weight is to the living nearly as 14 to 20‖, the dead weight of the whole would be 436$\frac{2}{20}$ lb. which, at 7s. 9d. per ſcore, the ſelling price, would come to 8l. 8s. 1½d. or nearly 4½d. per lb. a very comfortable profit, at this period of twenty days, eſpecially when corn is ſo dear.

Jan. 5, 1785, Hog N°. 4, weighed alive 199 lb. 8 oz. ſo that he gained in twenty days, ſince laſt weighing, 39 lb. 2 oz. which, as formerly, is near 2 lb. per diem. It is, however, here to be obſerved, that he did not get ſo much in this, as in the former twenty days, having in the firſt period gained 41 lb. 10 oz. and in the laſt, only 39 lb. 2 oz. Difference 2 lb. 8 oz.

N°. 4 was now killed, and his weight, as ſold for bacon, was - -	146 lb.
Weight alive - - -	199½
Or, - - -	14$\frac{2032}{3192}$

That is, 20 lb. alive yielded 14 lb. 67, or 14 and near $\frac{2}{3}$, or better than one half.

Loſs on two Hogs - -		1	3	10

It appears, as the general reſult of this experiment, that no profit ariſes from feeding Hogs with corn, when the prices of grain are high, except, perhaps, in the ſuperior quality of the bacon. The ſame general reſult was found by Mr. Young, in his Experiments, for which ſee Annals of Agriculture, vol. I. p. 333 to 353.

It is further to be obſerved, that, after attending twenty days there would probably have been a conſiderable profit on the four Hogs. After forty days, Hog N°. 4, that was then killed, yielded very little, to wit, 1s. 7½d. In twenty-two days more, that is, from the 5th to the 27th of January, there is a little loſs, 4d. to wit, on N°. 4. And upon the remaining two that were kept to the 22d of March, four months, there is the conſiderable loſs of 1l. 3s. 10d. ſo that there would appear to be an increaſe of loſs in proportion to the time they are kept; which is directly contrary to the common maxim of this country, which ſays, that Hogs pay beſt the laſt days or weeks of their feeding.

From this experiment, other calculations may be made. If the bacon had been ſold at 8s. per ſcore, there would ſtill have been a loſs of about 10s.

Had barley been at 24s. and the bacon at 7s. per ſcore, there would have been little loſs. And ſuppoſe the bacon at 7s. 6d. there would have been ſome profit; ſo that from this, and other experiments of the kind, a pretty accurate table may be made of the proportions of the prices of bacon, to thoſe of barley, or other grains.

In general, I ſuppoſe, if a farmer can fat his Hogs with corn, without loſs, though no apparent gain, at the market prices, that he will have a conſiderable, or very comfortable profit, in a ſure market for his corn at home, without trouble or expence; and in making, by that means, a quantity of very valuable dung, while he has the very beſt bacon for his table, or for ſale.

I did intend to have tried other Hogs upon ſoured meat, a method fallen upon by Mr. Young to profit, but circumſtances having prevented me, that ſhall be for another year—when, perhaps, other members of this ſociety may make the like, or other experiments in this way.

A. B.

The minute inſpection into the increaſe of animals during the time they are feeding, is inſtructive and curious; and thoſe who have never made ſuch experiments, nor attended to them made by others, will, on an attentive peruſal of Mr. Baxter's ingenious labours, greatly improve themſelves.

SECT. XXVI. AND XXVII.

SECTION XXVI, relates to Apples, Pears, and the making of Cyder. As we are promiſed, ſince the commencement of this Syſtem, the aſſiſtance of a Gentleman Farmer, reſiding near the city of Worceſter, whoſe abilities and extenſive practice enable him to treat this ſubject in a manner ſuperior to any thing of the kind ever ſubmitted to the public eye; we ſhould think ourſelves deficient in point of gratitude to our Subſcribers if we neglected ſo favourable an opportunity of communicating to them ſuch valuable information.

We therefore refer the reader to the article HUSBANDRY, where a variety of other detached matters relative to Agriculture will be duly noticed.

SECTION XXVII relates to Timber and other trees connected with Agriculture.

As the planting and management of all kinds of trees and ſhrubs are analagous to each other, and form a ſyſtem diſtinct and complete, had we divided the ſubject, it would have cauſed a troubleſome and diſagreeable difference; and to enter fully into it in this place, would be annexing that to Agriculture which has little to do with it; on this account we refer to NURSERY, and have engaged Mr. KERSHAW, of Shipſton, in the county of Warwick, whoſe abilities in ornamental and uſeful planting, and likewiſe in the management of a Nurſery, we can venture to aſſert will do credit to our choice, and give ſatisfaction to thoſe who wiſh to be well inſtructed on the ſubject.

SECT. XXVIII.

IMPLEMENTS USED IN HUSBANDRY.

WE at firſt intended to introduce the Huſbandry Implements previous to the ploughing, ſowing, &c. of land, but the REV. MR. COOKE having entirely new modelled his Drilling Machine, and rendered it at once the moſt ſimple as well as uſeful implement ever invented, it may now with juſtice be pronounced perfect. Mr. COOKE has alſo promiſed us a complete deſcription of this improved machine, which he is now preparing for the preſs. We are likewiſe favoured with various other new and uſeful Agricultural Implements invented and manufactured by the ingenious Mr. WINLAW, of Margaret-Street, Cavendiſh-Square, deſcriptions of which are not finiſhed. Theſe circumſtances obliged us to paſs this Section, which we can without the leaſt impropriety. We therefore inform the reader, that deſcriptions and the uſes of all the new and uſeful Implements in Agriculture will follow SECTION XXX of this Syſtem.

AGRICULTURE.

SECTION XXIX.

PLOUGHING, HARROWING, AND CLEANING LAND.

PLOUGHING, Harrowing and Pulverizing the Soil in a proper manner, are circumſtances which conſtitute an eſſential portion of the knowledge of a good huſbandman. It is deemed an error to plough land in very wet weather, and we think no emergency whatever ſhould induce a farmer to purſue a method ſo contrary to reaſon and experience. Stiff loams and clay cannot be laid too rough, and expoſed to the froſt and ſun during the time they are under a courſe of ploughing, in order to be cleaned from weeds, and meliorated, either by the intenſe heat of the ſummer's ſun, or the no leſs fertilizing influence of winter's froſt.

SAND, and looſe gravelly loam, require but little plowing; too much generates weeds, particularly thiſtles of various kinds.

As a particular deſcription of the various ſorts of thiſtles, with obſervations on their nature, and the methods of extirpating them, will doubtleſs prove a treat to our Agricultural readers, we preſent them with the following by the ingenious

MR. WILLIAM CURTIS, of LAMBETH MARSH.

SOME OBSERVATIONS ON THISTLES AS INJURIOUS IN AGRICULTURE, MORE PARTICULARLY THE SERATULA ARVENSIS OF LINNÆUS.

"There are no plants over which the œconomical farmer ought to keep a more watchful eye than the Thiſtle tribe. He is ſenſible that they are not only uſeleſs, as reſiſting the bite of moſt animals, the hardy aſs excepted, but that they occupy much ground; and being furniſhed with downy ſeeds, are capable of being multiplied to almoſt any diſtance. Hence in many parts of the kingdom, the farmers whoſe lands are contiguous unite in preventing the increaſe, by cutting them down before they ſeed; but this operation, though deſtructive to ſome ſpecies, will only palliate the bad effects of others.

"To be acquainted with the qualities of each kind, we muſt obſerve them with much attention, and view them in a botanical and philoſophical light: this alone will enable us to judge with certainty how far and by what means their deſtruction may be effected.

"The Engliſh Thiſtles meriting notice, as more or leſs noxious, are,

1. The Carduus Lanceolatus, or	Spear Thiſtle
2. Carduus Nutans,	Muſk Thiſtle
3. Carduus Paluſtris,	Marſh Thiſtle
4. Carduus Marianus,	Milk Thiſtle
5. Carduus Acanthoides,	Welted Thiſtle
6. Carduus Criſpus,	Curled Thiſtle
7. Onoperdum Acanthium	Cotton Thiſtle
8. Seratula Arvenſis,	Curſed Thiſtle

"The Spear Thiſtle is a large ſtrong plant, about four feet high, the extremity of each leaf running out into a long point; its heads are large, and it grows very commonly by the ſides of roads, near dunghills, and not unfrequently in fields and paſtures.

"The Muſk Thiſtle grows to the height of 2 or 3 feet, the heads hang down, and the flowers ſmell ſomewhat like Muſk; it is often found occupying whole fields, particularly on chalky or barren land.

"The Marſh Thiſtle is very tall and prickly; its heads are numerous, ſmall, and of a red colour; it grows abundantly in wet meadows, alſo in woods.

"The Milk Thiſtle has very large leaves, which are moſt commonly beautifully marbled with white. Near London it appears frequently on banks by road ſides: in which ſituation we alſo meet with

"The Curled and Welted Thiſtle. Theſe three ſeldom intrude into fields and paſtures.

"The Cotton Thiſtle is diſtinguiſhed by its ſize, (being perhaps the largeſt of the Britiſh herbaceous plants) and its white woolly leaves. It grows in the ſame ſituation as the three laſt-mentioned.

"The Curſed Thiſtle is more general in its growth than any of the others, being found not only by the ſides of the roads univerſally, but alſo in arable land, and is not uncommon in meadows, even in ſuch as are yearly mown. It is remarkably prickly, grows about three feet high; its heads are ſmall, the flowers purple, and frequently white. The ſcales of the heads are ſmooth, and may in a particular manner be diſtinguiſhed from all the others before-mentioned, by having a perennial root about the ſize of a gooſe-quill, which runs deep into the earth, and afterwards creeps along horizontally.

"Of theſe Thiſtles, all except the laſt are either *annual* or *biennial*; that is, remain in the ground not more than one or two years, unleſs renewed by ſeed. The laſt having a perennial root, continues in the earth, increaſing, and throwing up new ſhoots every year.

"Hence it will appear obvious, that if the firſt ſeven ſpecies of Thiſtles are cut down before they perfect their ſeed, the ground will be entirely cleared of them; and that the laſt-mentioned can no otherwiſe be deſtroyed, than by rooting it out, a proceſs which the following experiments will ſorrowfully convince the rural œconomiſt to be impracticable in large fields, and ſcarce to be performed even in an incloſed garden.

EXPERIMENT FIRST.

To aſcertain the effects of mowing the Seratula Arvenſis.

"The Hon. Daines Barrington, who is ever anxious to promote uſeful enquiries, deſired me to try whether this kind of Thiſtle could not be deſtroyed by mowing. A ſmall patch of them, about two feet ſquare, was accordingly planted in a good garden, in the year 1777. In the courſe of the ſummer they were mown three ſeveral times, but without any other good effect than that of preventing their ſeeding; for inſtead of being deſtroyed, the next ſpring they came up extremely vigorous, not only on the bed where they were firſt planted, but all around it to the diſtance of ſix feet.

EXPERIMENT SECOND.

To aſcertain the annual Increaſe of the Root of the Seratula Arvenſis.

"April, 1778, I planted in a garden a piece of the root of this thiſtle, about the ſize of a gooſe-quill, and two inches long, with a ſmall head of leaves, cut off from the main root, juſt as it was ſpringing out of the ground. By the 2d of November, 1778, this ſmall root had thrown out ſhoots, ſeveral of which had extended themſelves to the diſtance of eight feet; ſome had even thrown up leaves ſix feet from the original root. Moſt of theſe ſhoots which had thus far extended themſelves were about ſix inches under ground, others had penetrated to the depth of two feet and a half; the whole together, when dug up and waſhed from the earth, weighed four pounds.

"In the ſpring of 1779, contrary to my expectation, this thiſtle again made its appearance on and about the ſpot where the ſmall piece was originally planted. There were between fifty and ſixty young heads, which muſt have ſprung from thoſe roots, which had penetrated deeper than the gardener was aware of, although he was particularly careful in extracting them.

"From theſe experiments it appears deducible, that no plants are more eaſily deſtroyed than the generality of thiſtles, or with more difficulty than this one; there being no ſoil, however poor, in which it will not vegetate, nor earth ſo ſtiff but it will penetrate; in proportion, however, as the ſoil is rich, will be its increaſe.

"It were much to be wiſhed, that an inveſtigation of this evil had afforded a remedy: at preſent, none appears. It is, therefore, to be feared, that ſpudding or cutting them down cloſe to the ground, once or twice in the ſpring, is the only operation the farmer can perform to prevent their bad effects in deſtroying his crops on arable land, and rendering his paſtures unſeemly.

"As nature in the preſervation of this plant ſeems to have exerted her greateſt powers, it is poſſible that in ſome future period, uſes may be diſcovered to which it has not yet been applied.

"To the aſs it is the higheſt treat; and I have been credibly informed, that in ſome parts of Scotland, it is cut down as food for horſes.

"It would be well, if a plant ſo noxious in ſome reſpects could be rendered beneficial in others."

Some kinds of ſoil require deep ploughing, and others light; we have heard huſbandmen aſſert that they were friends in every reſpect, and on all ſoils, to light or ſhallow ploughing; and others profeſs themſelves advocates to a deep furrow where the rock were no impediment: theſe are aſſertions without reaſon; as where the ſoil or ſurface-earth is of a conſiderable depth, to ſometimes fetch up freſh mould may undoubtedly be an improvement, particularly if it has by means of a fallow, a crop of roots, or any other meliorating management, the opportunity of being in cultivation a ſeaſon previous to its being ſowed with corn.

The following inſtance of Deep Ploughing, by Mr. N. BARTLEY, near BRISTOL, contains ſomething ſatisfactory on the buſineſs.

EXPERIMENT ON DEEP PLOUGHING.

"FROM the experiments and reaſoning of Monſ. CHATEAUVIEUX, DU HAMEL, and others, I was determined to try the effects of Deep Ploughing; for this purpoſe I provided myſelf with a very ſtout plough, and began with a piece of land of about five acres on Briſlington Common, to which my experiments have been moſtly confined. The ſoil a rich loamy ſand, the colour that of a hazel-nut when fully ripe; the uppet ſtratum of a pretty uniform quality, to the depth of from 2½ to 4 feet. In the firſt place, I had to contend with the prejudice of the ploughman, who, for what reaſon he knew not, very ſtrongly objected to deep ploughing; however, I ſoon brought him to ſubmiſſion, and, not without much labour, he performed the buſineſs to my entire ſatiſfaction: the general depth was about nine inches.

"During the operation, the ground was viſited by moſt of the farmers in the neighbourhood, and the method univerſally exploded. By ſome it was ſaid I ſhould uot plough for them, though I would do it for nothing; by others, that it would not recover for ſeven years; and again, that it would be quite ruined. From all this I was not diſcouraged; and after giving the land two other ploughings, which were performed with eaſe and pleaſure to the ploughman, it was cropped with Lammas Wheat, and the produce was eſtimated, by ſome of theſe very farmers, at forty buſhels per acre. The next year it was manured with twenty cart-loads of a compoſition of half hog dung, and half virgin earth, part of the ſame field, and planted with potatoes. This crop was kept free from weeds, well hoed and earthed up, the produce not leſs than 140 ſacks, or 560 Wincheſter buſhels per acre. Next it was ſown with flax-ſeed, and produced two packs per acre, the pack 240lb. After this two ſucceeding crops of hoar-wheat, both good, ſay about 30 buſhels each crop per acre.

"The laſt ſeaſon it was ſown with black oats, and laid down with clover and rye-graſs ſeed. The oats I eſtimate at 64 buſhels per acre, which will appear moderate in compariſon of an experiment upon that grain, which I ſhall note in the ſequel.

"I attribute greatly to deep and frequent ploughing, the ſucceſs of theſe crops, and I perſiſt in the ſame method. It is probable, however, that ſome degree of caution may be neceſſary on particular ſoils."

Lands, which lie level, have evidently the advantage of thoſe which are in high ridges with reſpect to cleaning; croſs ploughing is impracticable on high ridged lands, without which ſtiff ſoils cannot be ſufficiently pulled to pieces. The old cuſtom of throwing land of a wet nature into very high ridges was certainly an error, particularly on the ſides of hills, or where there was a proper deſcent to admit of draining.

In grounds that require ridging, an error prevails, that ridges cannot be raiſed too high. High ridges labour under ſeveral diſadvantages; the ſoil is heaped upon the crown, leaving the furrows bare; the crown is too dry, and the furrows too wet; the crop, which is always beſt on the crown, is more readily ſhaken with the wind, than where the whole crop is of an equal height: the half of the ridge is always covered from the ſun, a diſadvantage which is far from being ſlight in a cold climate. High ridges labour under another diſadvantage in ground that has no more level than barely ſufficient to carry off water: they ſink the furrows below the level of the ground; and conſequently retain water at the end of every ridge. The furrows ought never to be ſunk below the level of the ground. Water will more effectually be carried off by leſſening the ridges both in height and breadth: a narrow ridge, the crown of which is but 18 inches higher than the furrow, has a greater ſlope than a very broad ridge where the difference is three or four feet.

To attempt to level land, that has lain in high ridges a long time, on a ſudden, is by no means judicious; as experience ſufficiently ſhows, that even the beſt vegetable mould, if buried for any length of time ſo far beneath the ſurface as to be deprived of the benign influences of the atmoſphere, become an inert, lifeleſs maſs, little fitted for nouriſhing vegetables; and conſtitutes a ſoil very improper for the purpoſes of the farmer. It therefore behoves him, to preſerve, on every part of his fields, an equal covering of that vegetable mould that has long been uppermoſt, and rendered fertile by the meliorating influence of the atmoſphere. But, if he ſuddenly levels his high ridges by any mechanical contrivances, he of neceſſity buries all the good mould that was on the top of the ridges in the old furrows; by which he greatly impoveriſhes one part of his field, without rendering ſervice to the other; inſomuch, that it is a matter of great difficulty, for many years after, to get the field brought to an equal degree of fertility in different places; which makes it impoſſible to get an equal crop over the whole of his field by any management whatever. We have frequently ſeen fields that have been thus levelled, in which, after thirty years of continued culture and good management, the marks of the old ridges could be diſtinctly traced when the corn was growing, although the ſurface was ſo level that no traces of them could be perceived when the corn was off the ground.

With carefully caſting the furrow, high ridges may, in the courſe of ſix or ſeven years cultivation, be brought almoſt on a level and without a material injury, by impoveriſhing the top or convex point of the lands.

Large ragged ſtones are frequently a great impediment to the plough; oftentimes people plough ſhallow, purpoſely to keep clear of them, and by that means are precluded from the benefits which deeper tillage would produce.

Stones above the ſurface may be avoided by the ploughman, though not without loſs of ground; but ſtones below the ſurface are commonly not diſcovered till the plough be ſhattered to pieces, and perhaps a day's work loſt. The clearing land of ſtones is therefore neceſſary to prevent miſchief. And as the blowing, when gunpowder is furniſhed, does not exceed a halfpenny for each inch that is bored, theſe ſtones come generally cheaper than to dig as many out of the quarry, for repairing roads and other purpoſes. In the next place, as the ſoil round a large ſtone is commonly the beſt in the field, it is purchaſed at a low rate by taking out the ſtone. Nor is this a trifle; for not only is the ground loſt that is occupied by a large ſtone, but alſo a conſiderable ſpace round it, to which the plough has not acceſs without danger. A third advantage is greater than all the reſt; which is, that the ploughing can be carried on with much expedition, when there is no apprehenſion of ſtones: in ſtony land, the plough muſt proceed ſo ſlow, as not to perform half of its work.

To clear land of ſtones, is in many inſtances an undertaking too expenſive for a tenant, and requires the aſſiſtance of the proprietor.

In cleaning land from weeds, particularly couch graſs, ploughing is neceſſary as ſoon as harveſt is over, and another croſs ways before the ſeverities of winter commence; taking care to drain off water, it lying in this ſituation till ſpring, a heavy harrow or drag ſhould be drawn over the land to pull it to pieces; the weight of the implement and other circumſtances according to the ſtrength of the ſoil.

It is a prevailing practice in the weſtern and midland parts of this country to breaſt-plough the ſurface of ſtubbles, and let them lie in that condition during the winter, this certainly anſwers a good purpoſe, as what was pared off becomes rotten, and mixes with the ſoil when the land is ploughed for oats or peas in ſpring. The expence attending this paring, or breaſt-ploughing, is generally about five ſhillings per acre; was a good horſe-plough uſed for the purpoſe, it would not be half ſo much; we know of no plough ſo well adapted for the purpoſe as one made by Mr. **WINLAW**, a deſcription and engraving, ſee under **IMPLEMENTS**.

The preſent altercation amongſt thoſe who mix philoſophy with ploughing and ſowing, reſpecting fallows, is in moſt reſpects ridiculous; no man in his ſenſes would wilfully ſuffer his land to be at reſt, and under expenſive ploughings and other management, if it was in condition to produce a crop. The antifallowiſts have entered their proteſt againſt the enriching influence of the ſolar rays, and declare that ſoil derives more fertility and vigour from being covered with ſucculent vegetables, than from the moſt judicious and beſt conducted ſummer fallow. If that is the caſe, why do thoſe who purſue the horſe-hoeing ſyſtem place ſuch confidence in ploughing between the rows of corn in ſummer, in lieu of manure? Moſt kinds of ſoil, if the ſpring happens to be dry may be cleaned before the proper time to ſow turnips arriving, or in time to plant late cabbage; this method renders fallowing for wheat unneceſſary, and the turnips or cabbages may be conſumed on paſture or arable, where they will be of great ſervice.

When land becomes full of couch graſs and other weeds, there is as much neceſſity for time and labour to clean it, as there is for water to waſh a garment when it is dirty: whether winter and ſpring ploughings will effect it, or a ſummer fallow is neceſſary, we muſt leave to the diſcretion of thoſe who pay the expences.

SECT. XXX.

SOWING, DRILLING, AND OTHER MEANS OF DEPOSITING SEED IN THE EARTH.

SOWING is the operation of diſtributing ſeed on the earth, from a veſſel or meaſure of a diſtorted oval conſtruction, adapted in ſhape to the ſide of the ſower, and called a ſeed lap, or ſeed lip, which in all probability owes its derivation to the ancient method of carrying the ſeed in an apron, or a lappet of the ſowers garment. The general practice is to deliver each caſt of ſeed from the hand of the ſower, at the time he advances his left leg; as in the action of walking, and to proportion the diſtance he ſteps, and the quantity of ſeed he throws each time, to the width of the land he is ſeeding.

This is the mode called broadcaſt; the ſeedſman going twice over the ſame ground; thoſe that are dexterous, ſow both right hand and left, which is a practice very convenient, and to be recommended to every young perſon's notice, as it is acquired with eaſe, if practiced early in life. On ſtubbles and fallows, when they are in a mellow, friable condition, all kinds of grain ſhould be ſowed under furrow, that is, before the land is ploughed, and ſo turned in with the furrow: it is a practice very cuſtomary to ſow one caſt before ploughing, and another after; but we cannot think it eligible, as the advantage, if any, muſt belong to one mode independent of the other, conſequently none can derive from uſing both. On land freſh broke up from graſs, and commonly called a ley, corn is generally ſowed after ploughing and harrowed in, except beans or peas which are not eaſily buried, and for that reaſon commonly ſowed under furrow. The quantity of ſeed neceſſary to ſow an acre of land, is generally more or leſs, according to the quality of the ſoil; the richer the ſoil the leſs ſeed, and the poorer the greater the quantity.

This is a maxim generally attended to, and by multitudes invariably purſued, but certainly liable to exceptions, if not totally founded in error.

No perſon ſhould invariably adhere to preſcribed rules, but deviate by making ſmall experiments and taking notice of the reſult, this only can correct error and lay a good foundation for improvements.

Thomas Le Blanc, Eſq. of Caveſham, in Suffolk, relates the following experiments in Mr. Young's Annals, Vol. I. p. 111.

EXPERIMENTS ON THE SEEDING OF SAND LAND.

1. ON one acre of poor Sand, worth about 3s. 6d. an acre, were ſown two buſhels of barley.

2. On the next adjoining acre three buſhels.

3. On the next four buſhels.

The reſult was, that the crop was beſt from two buſhels; next beſt from three; and the worſt from four.

The experiment was afterwards repeated on Sand, worth 7s. an acre, in which two buſhels produced 4½ quarters.

Three buſhels produced four quarters two buſhels, and

Four buſhels produced three quarters ſeven buſhels.

It is the obſervation of the farmers in the neighbourhood on the ſame Land, that where the chalk lies very near the ſurface, there the quantity of Seed muſt be increaſed.

As we have given theſe intereſting experiments on a poor ſandy ſoil, the following we think equally ſo on a **Cold Clay**. Annals, Vol. VII. p. 28.

EXPERIMENTS ON THE QUANTITY OF SEED ON COLD CLAY LAND.

By Mr. **Solomon Norman**, of **Cleveland, Yorkshire**.

I Have been a ſeedſman many years; the firſt oats that I ſowed, broad-caſt, was at the rate of nine pecks per acre; my acres are 10 great chains, and Wincheſter buſhels, the produce 40 buſhels; this field contained nine acres, had been in tillage 24 years, in the Cleveland courſe of oats, fallow, and wheat. At the ſame time, or nearly, I ſowed eight acres, an adjoining field, that had been in tillage eight years, in the ſame courſe as the former, with three buſhels per acre, the produce but 40 buſhels; the ſtaple of the latter being much deeper, and freſher than the former field, and ought to have produced double the former field. I am ſenſible, there is not a more pernicious practice than loading poor ſoils with too much ſeed; the nine acres, three years before, was ſown with three buſhels per acre, the produce only two quarters; as to the quantity of ſtraw, I could carry the produce of an acre on my back. I ſhould at once condemn ſix or ſeven buſhels, ſo large a quantity, mentioned in your tours, as would deſtroy our clay ſoils; their height would not exceed 10 or 12 inches, and be as light as chaff, their produce, perhaps, the ſeed again.

In 1785, ſowed 10 pecks per acre in April; at May-day, ſowed clover-ſeed on four acres, on two of which, I harrowed in the ſeed; the oats were in fine leaf, they were torn up a ſhame to be ſeen, and laid upon the ground thick. The other two acres, I bruſhed over, by putting a buſh of thorns into the harrows, which did not hurt the oats. The produce was, two acres harrowed, ſuperior to any four acres in the field, which contained 12 acres in all; ſome parts of this field was rank with wild oats, ſuch places did not exceed one foot high, and were as light as chaff, their ſtalks produced no more than a corn or two. I always increaſe the quantity of ſeed oats, on rich ſoils, in order to keep them from running too much into ſtraw, which is generally the caſe on rich land; otherwiſe to ſmother the weeds, for ſuch land will grow ſomething. I likewiſe find two buſhels of barley a ſufficient quantity on Clay Land, that is free from weeds.

"I have frequently ſown two buſhels of wheat on one acre, and two buſhels and a half on another, in order to compare the difference on cold-bottomed Clay Land, but found no difference. If two buſhels, broad-caſt, will not produce a good crop, there is no forcing the land with too much ſeed. As to ſteeps for wheat, they are of no ſervice at all. My mode of pickling wheat ſeed, is to ſprinkle urine, otherwiſe clean water, on the heap until thoroughly wet, then ſprinkle quick lime over it till thoroughly covered and white as duſt, then it is fit for ſowing. I recommend lime; but as to ſteeps, there is no health in them, the crops will be juſt as large a quantity without them.

"As to beans, we uſually ſow four buſhels per acre on Cold Clays; and the produce in general, is not one half ſo much as in Eſſex, where they ſow two buſhels per acre, and hoe one half of them up.

"In ſhort, I am an advocate againſt too much ſeed."

When the land is in proper condition to receive Seed, is an object of the firſt importance; to ſow dry and ſet wet, is proverbial; but as the huſbandman cannot influence the weather, nor always have ſuch as meets his wiſhes and convenience, he muſt be careful to let no favourable opportunity paſs.

When ſoil is eaſily pulverized, it is then beſt adapted to cover the Seed; ſeize this opportunity, and patiently leave the reſt to providence and nature.

DRILLING.

Drilling is the operation of depoſiting Seed in the earth in rows parallel to each other at any given diſtance, or at any depth beneath the ſurface; this may be effected by manual labour, but the proceſs is ſo tedious and expenſive, that the advantages gained by this ſuperior method do not yield an equivalent compenſation for time and labour. To remove this obſtacle, various machines have been conſtructed to facilitate the operation, and to render this valuable branch of Agriculture as profitable in practice, as it is rational in theory. The great inconveniencies attending implements for Drilling ſeeds have been the complexity of their conſtruction, and the difficulty of keeping them in repair, as the force with which a horſe moves a machine, is certain to derange ſome part or other of the work if it meets roots, large rag ſtones, or other powerful obſtructions, which occaſions diſappointment and loſs of time; very diſagreeable circumſtances to a farmer in the time of ſeeding. To obviate thoſe impediments a Drill machine ſhould poſſeſs ſimplicity of deſign, and ſtrength in its conſtruction, a regular delivery of the ſeed according to the quickneſs or ſpeed with which it is drawn; and ſo contrived as the ſeed may be ſtopped or let run in a moment, at the pleaſure and convenience of the perſon who attends it: and laſtly, the price of the Drill ſhould be ſuch as to render it within the purchaſe of thoſe who follow Agriculture from neceſſity. Without a combination of thoſe eſſential qualifications Drilling will never become general; and with them, we make not the leaſt doubt, no perſon will neglect the practice, whoſe ſoil is adapted to that mode of cultivation. This method of depoſiting ſeed is moſt certainly attended with many great advantages, when practiſed with diſcretion; and when hoeing is neglected, is the worſt management that can be purſued. Many have been kept from Drilling by the great expence of hoeing; an objection now we hope removed, by the Rev. Mr. Cooke's new conſtructed Horſe-hoe, which being an appendage to, and conſtituting part of the Drill, makes the practice cheap and expeditious.

We have attentively examined ſeveral Drill machines, and likewiſe have attended to the report of others from verbal accounts, and likewiſe written teſtimonials, and without heſitation acknowledge that the *Drill Machine, invented and made* by the Rev. Mr. **Cooke**, is, in its preſent plain and ſimple conſtruction, an implement which ſeems to render further improvement unneceſſary; this we are further warranted in aſſerting by letters received from two gentlemen of extenſive experience, who on reading our Syſtem wrote to the publiſher—theſe letters are annexed to the deſcription of the machine. We could not avoid making this declaration, thinking it our duty to the public, to exhibit merit to view wherever we find it. We ſhall alſo give deſcriptions and repreſentations of every other Drill machine worthy of notice.

When a perſon is in poſſeſſion of a Drill which will anſwer every purpoſe he could wiſh, it is not to be ſuppoſed every other mode of ſeeding is to be exploded; rather let him conſider the ſituation the land is in, and other obvious circumſtances, and judiciouſly follow that method which appears moſt eligible; this deliberate conduct will ſeldom diſappoint the expectation, and will make thoſe difficulties attendant on novelty, eaſy and familiar.

SETTING OR DIBBLING.

This method of planting grain we have every reaſon to believe lays claim to the greateſt antiquity, and is on ſtiff loams or clay greatly practiced at the preſent time; the mode of performing it, is with a ſtick about a foot long in one hand to make the hole, and immediately drop in the ſeed with the other, which ſhould be carried in a bag or apron, tied round the waiſt for that purpoſe. One particular advantage attend ſetting grain, it may be performed in rainy weather when other means cannot. As we were under the neceſſity of noticing this method under the article Wheat, Beans, &c. it will be uſeleſs to take further notice of it here.

The following ideas on Drilling, Hoeing, and other matters relative to this mode of huſbandry, which were never before publiſhed, were communicated to us by the Rev. Mr. **Cooke**, to whom we have been previouſly indebted for the account of the *Chicorie Sauvage*. As this gentleman's abilities and experience render him ſo well qualified to enlighten the uſeful Art of Agriculture, we ſhall lay his information before our readers without further preface.

AGRICULTURE.

OBSERVATIONS ON PRACTICAL DRILLING AND HORSE-HOEING.

By the Rev. James Cooke.

" FROM the extraordinary ſucceſs which has attended a proper uſe of the ſyſtem of drilling and hoeing in general, individuals, in hopes of equal ſucceſs, have been induced to adopt the ſyſtem, under ſuch abſurd practices as could only ſerve to bring it into diſrepute, not only by uſing the drill upon land ſhamefully exhauſted, and otherwiſe ſo foul and out of condition, as to afford no hopes of ſucceſs whatever, but alſo by neglecting the uſe of the hoe entirely.

" To thoſe who wiſh to adopt the drill ſyſtem with ſucceſs, it is ſtrongly recommended never to let two exhauſting crops together, but an exhauſting and an ameliorating one alternately. Wheat, rye, barley and oats are called exhauſting crops; beans, peaſe, vetches, turnips, cabbage, potatoes, and all kinds of artificial graſſes, are called ameliorating ones. It would be abſurd to ſuppoſe that one particular rotation of crops, ſelected from the above, ſhould be invariably adapted to all ſoils. It muſt remain with the cultivator to diſcover whether a better proceſs can be found out, than a bean fallow, &c. as a preparation for wheat upon ſtrong clays, and a turnip fallow, &c. as a preparation for barley upon light ſoils; and whether one or the other may be better adapted to the cultivation of wet or dry, light or ſtrong loams, as times, ſeaſons, and circumſtances may point out.

" The following hint for obtaining four valuable crops in two years, from the ſame land, is ſubmitted to the conſideration of active cultivators of ſtrong productive ſoils, to make the experiment, by drilling beans in rows at two feet apart, the land being previouſly manured and properly cultivated. In the month of June the ſpaces between the rows of beans being perfectly cleared from weeds, and the ſoil pulverized by repeated horſe-hoeing, two rows of turnip ſeed may be drilled in each ſpace at twelve inches apart, by the above drill machine, particularly as the direction of the coulters is now ſo readily influenced; or if the crop of beans ſhould be too high to admit of the uſe of the machine for drilling the turnip ſeed as above, a ſmall hand drill may be made and uſed for the purpoſe. When the beans are drawn and carried, the land will be ſtocked with a young crop of turnips in rows at twelve inches apart, which will admit of the uſe of the horſe-hoe, in clearing the ſpaces between the rows of turnips from weeds, &c. In the middle of theſe ſpaces wheat may be drilled in October, or any other period previous to the turnip crop being ſo luxuriant as to exclude the proceſs. In the ſpring the turnips and young crop of wheat may be fed off together by ſheep, or the turnips may be drawn; by which means the turnip crop will be extirpated, but the young plants of wheat will remain, to go on for a crop, in drills or rows at twelve inches apart, which will admit of horſe or hand hoeing as in other inſtances: at the laſt hoeing of this crop of wheat, turnip ſeed, rape, or cole, &c. may be diſtributed in the intervals, which will afford great plenty of food for ſheep or cattle in the winter. This proceſs of obtaining four crops in two years has but lately occurred to me; it will ſpeedily be put in practice, and in the hands of activity and induſtry I have no doubt of its ſucceſs ſuperior, perhaps, to any other rotation of crops heretofore adopted.

" Practical as well as ſcientific agriculturiſts in the drill ſyſtem have differed, and ſtill differ, in their opinions reſpecting the moſt advantageous diſtance at which grain ſhould be depoſited in rows or drills. If it is in my power to throw any light upon this undetermined point, I ſhall eſteem the attention I have paid to the circumſtances not altogether uſeleſs.

" In the year 1784, I made an experiment in order to aſcertain the moſt advantageous diſtance for drilling, by depoſiting wheat in rows at different diſtances of from 4 to 24 inches apart, varying 2 inches each diſtance; ſo that the progreſſive order of the different diſtances ſtood 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24 inches. During the growth of the experiment, the ſpaces between the rows were all hoed at ſeaſonable times, as well as the reſpective diſtances would admit of. At harveſt the rows were ſeparately reaped, when it appeared that the produce from the rows No. 10 and 12 were nearly equal, but ſuperior to any of the others. As I intended to make the public acquainted with the reſult of this experiment, I was very particular in ſtating the exact produce of each reſpective row, but the paper is now loſt or miſlaid, on which account I am induced to ſubmit to the conſideration of the curious a mathematical plan for aſcertaining the moſt approved diſtance for drilling and hoeing, in hopes of exciting a number of practical drillers to make experiments, in order to aſcertain upon different ſoils, the moſt advantageous diſtance.

" It is univerſally allowed by ſcientific and incontrovertibly proved by multitudes of practical drillers, that their crops have been conſiderably improved, by the ſoil being thrown up to the rows of corn, ſo as to cauſe fibres to iſſue from the firſt joints of the ſtems above the ſurface of the land, which, without much accumulation of the ſoil to the plants, would never have exiſted.

" This premiſed, it appears reaſonable to diſcard drilling at every diſtance which will not admit of the ſoil being earthed up to the plants as above; which happens to be the caſe with drills at every diſtance under 10 inches apart, ſuppoſing the firſt joints of the ſtems to be formed two inches above the ſurface of the land, and the depth of the hoeing to be performed two inches under the ſurface.

" Where it is ſelf-evident that half the quantity of ſoil diſplaced by the hoe, and contained in the triangle DEF, *pl.* I. *fig* 1. will be required to fill the triangle GHI, ſo as to reach the firſt joints of the ſtems C above the ſurface of the land; but ſoil in a dry, pulverized ſtate as it ought to be when it is earthed up by the hoe to the rows of corn, will not reſt or remain ſtationary at an angle greater than 45 degrees, or the inclination G F. Therefore, in order that fibres may be encouraged to iſſue from the firſt joints of the ſtems above the ſurface of the land by means of the ſoil being diſplaced by the hoe, and earthed up to the ſaid joints C: the ſpaces between the rows of corn muſt be ſuch that the triangle DEF and GHI will be equal, as in fact they will be when the ſpaces between the rows of corn are 10 inches apart.

" On the other hand, if the ſpaces between the rows of corn are leſs than 10 inches, ſay 7 inches wide, *fig*. 2, and I here allude to the diſtance of 7 inches for Mr. Winter's ſerious and candid conſideration, ſince he avers it to be the moſt advantageous diſtance: in which caſe, if fibres muſt be encouraged to iſſue from the firſt joints of the ſtems C, above the ſurface of the land, a column of ſoil equal to the triangle GHI will be required to earth up the plants to the ſaid joints C; but as the triangle GHI exceeds the triangle DEF, ſo will be the deficiency of ſoil required for earthing up the plants to the joints C, at leaſt it will not reach the joints C; in which caſe the idea of cauſing fibres to iſſue from the ſaid joints C, by means of the ſoil, of the ſpaces drills at 7 inches apart, being earthed up, as above, is manifeſtly abſurd.

" Individuals have wounded the reputation of the Drill ſyſtem materially, and retarded its progreſs, by attempting to introduce it upon their lands, with an eye to the circumſtance of Drilling only, for ſucceſs, without paying the leaſt attention whatever to the circumſtance of hoeing; whereas nothing could be more abſurd.

" When the hoe is conſidered as the immediate and moſt eſſential cauſe of ſucceſs in Drilling, and the machine as an accommodation to the hoe, the extraordinary ſucceſs which has attended a proper and ſeaſonable uſe of both in numberleſs inſtances, will ceaſe to appear any longer myſterious to thoſe who have made an improper uſe of the Drill, and totally neglected the uſe of the Hoe.

" If weeds are ſuffered to grow all over the ſpaces between Drills at 12 inches apart, the chance of their choking the corn will be in their favour, nearly as 11 to 1; whereas, if the weeds are all cut up in their infancies, by the Hoe, the triumphant ſtate of the crop over weeds will then be as 12 to 0.

" Wheat and rye cannot be hoed too early in the ſpring, provided the ſoil is dry enough to admit of being previouſly rolled. Nothing facilitates and expedites Hoeing ſo much as rolling, by pulverizing the ſoil, and levelling the ſurface; but ought by no means to be done, when the ſoil is not dry enough to quit the roller.

" The wings, or molding plates of the Hoe, which are calculated to earth up the ſoil to the rows of corn, ſo as to cauſe roots to iſſue from the firſt joints of the ſtems above the ſurface, which otherwiſe would not have exiſted, ſhould never be uſed for the firſt hoeing; ought always to be uſed for the laſt hoeing, except when land is to lie down with ſeeds; and uſed or not uſed, at the option of the farmer, when any intermediate hoeing is performed.

" The laſt Hoeing, or earthing up, ſhould not take place till the crop is eight or ten inches high, or till the young ears of corn are ſo far advanced in the ſtems, as to be above the ſurface of the ſoil, when the earthing up is finiſhed. The young ears of corn will, on diſſecting a few ſtems, be found to exiſt (in embryo as it were) much ſooner than is generally apprehended.

" The abſurdity of rolling any crop after the young ears are formed, and of earthing up the ſoil before they are advanced in the ſtems above the ſurface of the ſoil, muſt be ſelf-evident. In the former inſtance they will be cruſhed by the roller; in the latter they will be ſmothered by the ſoil. The young ears of corn will be found to exiſt, as ſoon as the ſecondary or coronal roots are formed.

" The above obſervations on Hoeing wheat and rye, are applicable to the Hoeing of ſpring-crops; only the firſt Hoeing of barley, oats, &c. ſhould take place as ſoon as the ſecond blade or leaf of the young ſtem appears. And of beans, peaſe, &c. as ſoon as the plants may be diſtinguiſhed in the rows.

" The beſt ſeaſon for Hoeing, is two or three days after rain, or ſo ſoon after rain as the ſoil will quit the inſtrument in Hoeing. Light dry ſoils may be hoed almoſt any time; but this is far from being the caſe with ſtrong clay ſoils. The ſeaſon for Hoeing ſuch is frequently very ſhort and precarious; every opportunity, therefore, ſhould be attentively watched, and eagerly embraced. The two extremes of wet and dry, are great enemies to vegetation in ſtrong clay ſoils; the bad effects of the former, though difficult to guard againſt, are nevertheleſs to be remedied, in ſome meaſure, by ploughs of a better conſtruction, and more properly conducted, than ſuch as are commonly met with in moſt ſtrong ſoils. For if the wing or feather of one plough-ſhare was made nearly as wide as the intended furrow, and fixed ſo as to work parallel to the ſurface of the land, the underſide of every furrow would be cut parallel to the ſurface; and a ſmooth under-floor, poliſhed by the bottom of the plough, would be found beneath every furrow, forming a regular plain, with an uniform deſcent from the top of the ridge into the water furrows; upon which poliſhed floor, all ſuperfluous water, after filterating through the looſe ſoil, or furrows turned over by the plough, would readily find its way in the water-furrow, which would prevent its ſtagnating in the ſoil, at leaſt ſo as to ſtarve the plants. But ſo far from guarding as much as poſſible againſt the ill effects of ſuperfluous water thus ſtagnating in clay ſoils, the conſtruction of the ploughs, commonly made uſe of in ſtrong clays, and the method of conducting them in many parts of this kingdom, have a direct tendency to the contrary; this is done by working their ploughs in ſuch a poſition, that the wing or feather of the ſhare, being neither ſo wide as the intended furrow, nor parallel to the ſurface when at work, but forming an angle of forty or fifty degrees with the ſurface; or in other words, moving in an oblique direction to the ſame, turns over, not a ſquare or parallel, but a triangular furrow: in which caſe it is ſelf-evident, that ſuch lands are only half ploughed; that there will be ſo many ridges of faſt undiſturbed ſoil, as there are furrows, forming ſo many troughs or trenches; and that of all the ſuperfluous water that ſhall fall upon ſuch lands, ſo much only as ſhall remain over and above filling the trenches, will be able to find its way into the water furrows; for ſome clay ſoils, indeed all ſoils when puddled, will hold water, conſequently ſo much water as the above trenches ſhall contain, will remain there, till it is evaporated by ſun and air, ſtarving the plants, and puddling the ſoil to ſuch a degree, that the nutritive quality in the food of plants becomes ſo far impaired, as not to be reſtored; or if it ſhould, the tender fibres of the roots of plants may be turned to putrefaction, ſo as to be incapable ever after of anſwering their intended purpoſe in promoting vegetation.

"As to the bad effects of ſtrong clay ſoils caking in dry weather, nothing is more eaſy to prevent; for there is a period, between the time that clay ſoils run together, ſo as to puddle, by ſuperfluous wet, and the time of their caking upon the ſurface, that they are as tractabe as need be; now this is the period, this is the juncture for hoeing; and ſo much land as ſhall be thus ſeaſonably hoed, will not cake or cruſt upon the ſurface, as it otherwiſe would have done, till it has been ſoaked, or drenched again with rain; in which caſe the Hoeing is to be repeated, as ſoon as the ſoil will quit the inſtrument, and as often as neceſſary; by which time the crop will begin to cover the ground, ſo as to act as a ſcreen to the ſurface of the land, againſt the intenſe heat of the ſun, and thereby prevent, in a great meaſure, all the bad effects of the ſoil's caking in dry weather.

"When land is to be laid down with ſeeds, the ſeeds muſt not be ſown as uſual when the grain is ſown, but the day the laſt Hoeing is to be performed. If ſeeds are ſown when barley is ſown, Hoeing is excluded, conſequently the great advantages of Drilling are loſt; but not being ſown till the laſt Hoeing is juſt going to take place, every purpoſe is anſwered. For the crop is not only improved by Hoeing, but the ſoil in the ſpaces between the rows of corn, being cleared from the weeds, and pulverized by Hoeing, will be in much better condition to receive the ſeeds; and the ſeeds being ſown broadcaſt juſt before the laſt Hoeing, will be incorporated with the ſoil by the action of the hoe, ſo as to vegetate better, and produce a much ſuperior crop. A ſmall and ſimple apparatus being added to the machine, graſs ſeeds may be depoſited in the ſame Drills with the barley, and at the ſame time; alſo in the ſpaces between the rows of corn, at the laſt Hoeing.

"Such ſtrong weeds as may grow in the rows of corn, and out of the reach of the Hoe to cut up, ſhould be plucked up by hand, to prevent their coming to maturity, and dropping their ſeeds upon the ſoil, that has been previouſly made clean by Hoeing.

"It is here obſerved, that where this method of ſowing graſs-ſeeds before the laſt Hoeing is intended to be put in practice, the crop (which is generally barley) ſhould be ſown early, at leaſt within the month of March, or by the middle of April, that the graſs-ſeeds may have time to vegetate before the hot weather commences, otherwiſe they may be burnt up by the intenſe heat of the ſun, as they ſpring out of the ground; which has been the caſe in a few inſtances, where the barley was not ſown before the month of May: and the cauſe of a failure in graſs ſeeds has been very erroneouſly attributed to the above proceſs of ſowing them before the laſt Hoeing: whereas the true cauſe of the failure has ariſen from ſowing the barley crop too late, and thereby poſtponing the ſowing of the graſs-ſeeds at the laſt hoeing ſo long, that the intenſe heat of the ſun has burnt them up as they have vegetated.

"Where a crop from the graſs-ſeed is of the utmoſt conſequence to a farmer; and the barley cannot poſſibly be ſown early enough to admit of the graſs-ſeeds being ſown at the laſt hoeing; it is recommended to ſow the graſs-ſeeds as in the uſual way, when the barley is ſown, and forego the advantages of hoeing. In this inſtance it may be aſked, Wherein conſiſt the advantages of drilling, if hoeing is excluded.

"In this caſe the advantages of drilling will conſiſt in ſaving more than half the ſeed, and producing a crop ſuperior to broadcaſt or hand ſowing, though not ſo great as if hoeing had taken place.

"To inſure ſucceſs in Drilling it is of the greateſt conſequence that land be reduced to a proper ſtate of cultivation previous to the time the proceſs of Drilling takes place; in which caſe, a crop equal to the production of the ſoil may reaſonably be expected, provided the buſineſs of Hoeing is properly attended to, and ſeaſonably performed.

"In ten days or a fortnight, more or leſs, after ſpring corn is ſown, the tillering or multiplying of the additional ſtems or offſets will commence, the number of theſe additional ſtems or offſets will uniformly be in proportion to the quantity of pabulum or food of plants contained in the ſoil at the time the above tilluring of the ſtems commences; and the net produce of any given crop will generally be in proportion to the number of ſtems ſo tillured; conſequently, in order to obtain the beſt crop of corn, which any given land is capable of producing, it is eſſentially neceſſary, that the ſoil ſhould be in the beſt ſtate of cultivation, of which it is capable, at the time the grain or ſeed is depoſited in the land.

"On the contrary, if grain or ſeed is ſown when the ſoil is out of condition, i. e. not properly pulverized and ameliorated for the reception of the ſeed, which frequently happens when the ſowing of the ſeed takes place immediately after the plough, on a freſh, waxy furrow; in which caſe, if a dry ſeaſon ſhould ſet in, the greateſt part of the pabulum or food of plants, will, during the dry ſeaſon, be ſet faſt and locked up in the dry hard clods: the tilluring will nevertheleſs begin to take place at the uſual time, viz. in ten days or a fortnight after the ſeed is ſown, without waiting for ſo much of the pabulum or food of plants, as was ſet faſt in the dry clods, being ſet at liberty to aſſiſt vegetation, and will conſiſt of ſo many ſtems or offſets, as the pabulum or food of plants, contained in the looſe pulverized ſoil only, ſhall be able to ſupport and bring to maturity. Afterwards, when rain comes, and ſets at liberty ſo much of the pabulum or food of plants as was locked up in the dry clods when the above tilluring was performed, there will be a ſurplus of pabulum to ſpare, over and above what was neceſſary to bring to maturity the number of ſtems tillured as above; this additional pabulum will prompt an additional number of ſtems at an unſeaſonable time, which ſo far from adding to the crop at large, will amount to a conſiderable drawback upon it; this is eaſily obviated, and many advantages derived, by ploughing up all ſtrong ſoils, intended for cropping before Chriſtmas, or as ſoon after as may be, in order to have the benefit of froſt and ſnow, which will, by pulverizing and ameliorating the ſoil, prepare it for the reception of the ſeed, much better than all the ploughing and harrowing in the world can poſſibly do, at, or juſt before, the time of ſowing grain or ſeed.

"It is well known, that all ſoils, and eſpecially ſtrong wet ſoils, are pulverized and ameliorated by froſt. If the cauſe of theſe effects were as well underſtood, as the effects themſelves are viſible, one would think there could not be found a ſingle cultivator of land who would not gladly avail himſelf of the means of his land being thus pulverized and ameliorated, without the labour of men and horſes, or any other expence but that of ploughing up his land before winter.

"It is not by reaſon of the effects which froſt has upon the ſoil, (for upon a dry ſoil froſt has no power at all) but upon the water contained in the ſoil, that the ſoil becomes pulverized and ameliorated. It is very eaſy to conceive, a given quantity of water, contained in a given quantity of ſoil, to be divided into an almoſt infinite number of globules or particles, each capable of being conſiderably enlarged and expanded by froſt. But before one of theſe particles of water can become conſiderably expanded and enlarged by froſt, ſo as to occupy a larger ſpace in its congealed ſtate than it occupied in its watry ſtate; the texture of the particles of ſoil contiguous to, and ſurrounding the ſaid particle of congealed water, muſt be torn to pieces in giving way to the enlarged particle of congealed water.

"In like manner, the whole given quantity of water, contained in any given quantity of ſoil, by being enlarged and expanded by froſt, will break and tear to pieces the texture of the whole ſoil, in yielding to the ſuperior force of the congealed water, as it expanded; by which means the ſoil, by being thus torn to pieces, will not only become pulverized and ameliorated; but in proportion as the pores are thereby opened, ſo will be the quantity of pabulum, or food of plants, imbibed from the atmoſphere.

"From whence it may be juſtly and truly ſaid, that if land is only ploughed before winter, it will become more or leſs tilled and manured without labour or expence, ready for the reception of ſeed in the ſpring.

"For the above reaſons I apprehend it is, that ſeveral of my

Milne del.

Published as the Act directs by C. Cooke, No. 17, Paternoster Row, April 3d. 1789.

Agricultural Correſpondents, who ſpend a conſiderable ſhare of their time and attention to improvements in cultivating the ſoil, are fond of Drilling upon what they call a ſtale furrow, i. e. when land has been expoſed to the influences of the atmoſphere for ſome time after it is ploughed previous to the time of ſeedneſs.

"As far as my obſervations and experience have extended, no one need fear drilling a piece of land, though it ſhould not be ſo clean from weeds as might be wiſhed, provided the ſoil is powerful and productive, and reduced to a proper tilth for the reception of the ſeed, it will be in vain, during the growth of that crop, to retrieve the loſs, which will uniformly attend ſo groſs a neglect.

"However doubtful it might be a few years back, whether the Syſtem of Drilling would ever become general, there is now every reaſon to believe, that it will, in a few years more, become the prevailing ſyſtem with all the active, the induſtrious, and enlightened cultivators of this iſland. Indeed it is already become the favourite ſyſtem with multitudes, upon ſo extenſive a ſcale, that individuals, who, through an improper uſe of the ſyſtem, have not had equal ſucceſs, begin to find themſelves hardly at liberty to condemn it, as that would ſubject them to the reproach of their more ſucceſsful friends and neighbours; but ſeem rather diſpoſed to adopt their ways and methods; by this means many converts are daily made; and as one ſingle convert will make many more, there is every reaſon to believe, that the Syſtem will ſoon become general: and, whenever that period arrives, I can, with the greateſt propriety, and without fear of running into error, pronounce the product of grain in this kingdom to be vaſtly ſuperior to what it is at the preſent time."

IMPLEMENTS USED IN HUSBANDRY.

A A. Shafts of the machine, applied to the axis of the wheels BB, ſo that a horſe may go on the land or in the furrow.

C C. Coulter beam, with mortices in it, at different diſtances.

D D. Handles of the machine, applied to the coulter beam at CC, by means of ſcrew bolts and nuts; alſo to the axis of the wheels, by hooks and eyes, or ſtaples.

E E. Upper ſeed-box, in partitions.

F F. Lower ſeed-box, in partitions.

G, G. Slides, between the upper and lower ſeed-boxes, to prevent the grain or ſeed from deſcending too faſt into the lower boxes; by elevating or depreſſing of which, the quantity of grain or ſeed diſtributed in the drills may be varied at pleaſure.

H H. Cylinder, with cups or ladles, by which the grain or ſeed is taken up from the lower ſeed-box and dropped into the funnels I, I, I, I, and directed thereby into inciſions made in the land by the coulters K, K.

I. A chain and hook, applied to the coulter beam and axis of the wheels, to prevent the coulter going too deep in the land, and to prevent the coulter beam dropping ſo low as to unſhip the upper funnels in croſſing deep furrows or gutters.

M. A pin of iron, projecting from the coulter beam, which being lifted on to the hook L at the end of the land, will bear the coulter out of the ground, while the machine is turning round, without any labour of the man, who attends the machine, in ſupporting the ſame.

N. A cog wheel upon the nave of the wheel B.

O. A cog wheel upon the gudgeon or axis of the cylinder H, which is turned by the wheel N.

P. Lever and ſtring, paſſing over a pully to the axis of the cylinder H; by moving the lever P to a notch in the ſtaple Q, the wheel O will be lifted out of generation with the wheel N, by which means the diſtribution of the grain or ſeed may be ſtopped at pleaſure, particularly at the head land, while the machine is turning round.

R. An iron bar with holes in it, applied to the croſs bar of the ſhafts by a ſtaple, and to the front edge of the ſeed-box. By means of this box, the ſeed-box may be elevated or depreſſed, ſo as to keep the top of the ſame horizontally level, whether going up or down ſteep hills.

S, S. Staples in the ends of the ſeed-box, for the reception of two ſlides of wood, with canvas applied to the ſame, alſo to a ſmall ſtaple in the end of the coulter beam, to prevent the wind from interrupting the grain or ſeed in its deſcent from the cups or ladles to the funnels or conductors I, I.

T, T. Hooks in the handles of the machine, to which weights may be applied to force the coulters, if neceſſary, into the ground.

Fig. 2, repreſents the ſhafts, the axis and wheels, the coulter beam, with handles applied to the ſame, as in *fig.* 1; and the ſaid Drill Machine is converted into a Horſe-hoe, only by taking away the ſeed-box E E, the cylinder H H, the funnels I, I, I, I, and the coulters K, K, as in *fig.* 1, and introducing the Hoes A, A, A, A, A, A, in the places of the coulters.

B. A guide projecting from the hoe beam, which the perſon who conducts the inſtrument muſt keep directly over one of the rows of corn, when hoeing drills at nine inches apart, and over the middle of one of the ſpaces between the drills when hoeing the ſame at twelve inches apart. And ſo long as he does this, it will be impoſſible to injure the crop, by cutting up any of the rows of corn. He will, with the greateſt facility, keep the guide B directly over one of the rows of corn, or over the middle of one of the ſpaces between the rows of corn, by means of the hoe beam with ſix hoes fixed in it, readily moving to the right or left upon the principles of the pentagraph, ſo as to counteract the irregularity of the horſes draught, notwithſtanding he ſhould deviate from the direction in which he ought to go two feet or more.

As Mr. Cooke, the publiſher of this Work, has received two Letters reſpecting the Drill Machine we have juſt deſcribed, we think this the moſt proper place to introduce them.

Atherston upon Stour, near Stratford on Avon, Warwickshire, 25 Oct. 1788.

"SIR,

"Finding you are favoured by the Rev. Mr. Cooke with the particulars of his newly improved Drill Machine, I ſend you the following, and which you have the liberty to publiſh in your Encyclopædia, as I am always happy to ſerve the man to whoſe inventions I am ſo much indebted.

"For three years laſt paſt, I have uſed the Rev. Mr. Cooke's old Drill Machine with extraordinary ſucceſs, particular accounts of which you will find in the fifth and ſixth volumes of the Tranſactions of the Society of Arts, Manufactures, and Commerce of London. The crops of this year are not yet threſhed; but I have reaſon to believe they will not fall ſhort of the produce of the two preceding years, conſidering the dryneſs of the ſeaſon. Some time ſince, I was informed that Mr. Cooke had made a great improvement in his Drill Machine, particularly by annexing to the ſame a method of horſe-hoeing. This newly improved Drill with horſe-hoes I procured a few days ſince, and have already uſed it upon 60 acres of land, in drilling wheat; and, as far as I am able to judge, it will turn out a real improvement. In juſtice to the inventor, I have only to obſerve, that Mr. Cooke has exhibited a wonderful diſplay of mechanical knowledge, not only by ſimplifying, but by adding to the ſame, a method of horſe-hoeing without any additional apparatus, and has thereby rendered to this country an everlaſting ſervice.

"I am, Sir,
your moſt humble ſervant,
JOHN BOOTE."

To Mr. C. Cooke,
Pater-noſter Row,
London.

Clapham Park, Surry, 29 Oct. 1788.

"SIR,

"As I perceive you treat largely on Agriculture, in the Dictionary of Arts and Sciences you are publiſhing, and being always happy in doing juſtice to merit, I chearfully avail myſelf of an opportunity to inform you, that I have ſucceſsfully uſed the Rev. Mr. Cooke's Drill Machine for two years paſt; I mean his firſt, for which he obtained his patent about four years ago, and has, I believe, ſold ſeveral hundreds of them; and which appeared to me ſo well adapted to the work for which it was intended, that I really had no idea there was a poſſibility of rendering it more uſeful and perfect.

"But juſtice to Mr. Cooke calls upon me to ſay, that I have this ſeaſon drilled ſeveral fields of wheat with his new improved Drill, for which I underſtand a new patent is granted, and find it manifeſtly improved in every reſpect; all its parts being under the eye of the ploughman, and their deſign and uſe evident to every huſbandman; and, by making a ſet of horſe-hoes part part of the whole, it is now become the moſt perfect inſtrument ever yet offered to the public; and to thoſe who know the ſuperiority of the drill huſbandry over the broad-caſt. As from experience I know the great advantages which attend the Drill Syſtem; from the ſame convincing evidence I find the Rev. Mr. Cooke's Drill Machine equally ſuperior to every other which I have ſeen or tried; and I aſſure you, I take every opportunity of informing myſelf as well by obſervation as experiment.

"I write in haſte, and have only time to add, that in the European Magazine for September laſt, page 214, you will find a letter I wrote to the Editor on that ſubject.

"I am, Sir,
your moſt humble ſervant,
CHRIS. BALDWIN."

Mr. Cooke,
Paternoſter-Row,
London.

On inſpecting the Tranſactions of the Society of Arts, referred to by Mr. Boote, we find a gold medal was, laſt year, adjudged to him by that Society, as being the cultivator who had brought the Drill Syſtem to the greateſt perfection, he having drilled near *five hundred acres* of grain in one year, and with amazing ſucceſs. And as the Rev. Mr. Cooke's Drill effected this, it ſurely will be uſeleſs for us to ſay more on the ſubject.

We next lay before our readers two other Patent Drill Machines, of which the reſpective authors give very flattering accounts, but as we have no teſtimonials of the performance of either of them, our readers muſt be content with what the Patentees are pleaſed to ſay in commendation of their own works.

THE DESCRIPTION AND USE OF MR. WINTER's NEW INVENTED PATENT DRILL MACHINE.

THIS Machine (ſays Mr. W.) is univerſally acknowledged to be ſuperior to any hitherto invented; it is ſo ſtrong that nothing but the greateſt violence can injure it; and is conſtructed on ſuch plain mathematical principles, as to be worked by any perſon of the loweſt capacity. It depoſits grain, pulſe, turnip, carrot, or any other ſeed, with the greateſt accuracy, at any required depth in the earth, from the ſurface to ſix inches, at any required diſtance from 6, 7, 8, 9, to 40 inches between the rows, and may be inſtantaneouſly regulated ſo as to increaſe or decreaſe the quantity ſown, which is immediately covered. One man, a boy, and two horſes, can Drill ten acres of light, and eight acres of ſtiff land in one day; and from one buſhel of ſeed wheat, and one buſhel and a half of barley, will produce a crop of from 6 to 20 buſhels per acre, according to the richneſs of the ſoil, more than when ſowed by the common mode of huſbandry.

The Machine may be ſeen at the Exchange, or at Mr. HANCOCK's, wheelwright, Old-market, Briſtol. Orders to be directed to Mr. G. WINTER, Briſtol. Price ſixteen guineas.

REFERENCE to Plate I. *Fig.* 7.

Repreſents a front view of the Machine when at work, with ſix coulters faſtened on, depoſiting grain at the depth of two inches, in drills at ſeven inches diſtance.

A. The fore flap turned up, and the back board taken off, for the purpoſe only of repreſenting the inſide work, which, when Drilling in the field, is all incloſed: it then appears as a box between two wheels, and all the inſide work is perfectly ſecured from the effects of the moſt tempeſtuous weather.

B. The frame.

C. Iron plates, in which the gudgeons of the fore wheels are placed, and may be removed to any required depth.

D, D. The two hind wheels with ſpikes, which are for the purpoſe of preventing the wheels from ſliding over rough ground or clods, and by the ſpikes penetrating into the earth, the wheels are forced round, by which the grain is delivered; for when the wheels ſtop, or ſlide, no grain is diſcharged.

E, E. Iron rings faſtened to the fore-ſtandards, to which the chains are fixed, for drawing the Machine.

F. Coulter-bars with grooves, through which the coulters are placed at any required diſtance, from 6, 7, 8, 9, 10, to 36 inches or more.

1, 2, 3, 4. Six coulters numbered between the bolt-holes, with figures for ſetting the coulters, ſo as to depoſit the grain at any required depth; for inſtance, when the bolts are placed over N°. 2, the grain is depoſited at two inches deep; when over N°. 3, at three inches deep; and ſo on.

G. Six cylinders, which occaſionally ſlide off and on the axis, ſo that the whole, or any number of them, may be fixed at any required diſtance.

H. Boxes which contain the ſeed.

I. Conductors, into which the ſeed is delivered out of the cylinders, and conveyed into the grooves, in the back part of the coulters.

K. The axis, which paſſes through the cylinders and large wheels.

PATENT UNIVERSAL SOWING MACHINE,

BY MR. JOHN HORNE, DOVER.

" THIS Machine, whether made to be worked by hand, drawn by a horſe, or fixed to a plough, and uſed with it, is extremely ſimple in the conſtruction, and not liable to be put out of order; as there is but one movement to direct the whole, nor does it require any ſkill in working. It will ſow wheat, barley, oats, rye, clover, cole-ſeed, hemp, flax, canary, rape, turnip, beſides a great variety of other kinds of grain and ſeeds broad-caſt, with an accuracy hitherto unknown. It is equally uſeful in the New Huſbandry, particularly when fixed to a plough; it will then drill a more extenſive variety of grain, pulſe, and ſeed, (through every gradation, with regard to quantity) and deliver each kind with greater regularity than any Drill-Plough whatever. When uſed in this manner, it will likewiſe be found of the utmoſt ſervice to farmers who are partial to the old huſbandry, as, among many other very valuable and peculiar properties, it will not only ſow in the broad-caſt way with a moſt ſingular exactneſs, but ſave the expence of a ſeedſman; the ſeed being ſown (either over or under furrow at pleaſure) and the land ploughed at the ſame operation.

" Perhaps a fair and deciſive experiment for aſcertaining the ſuperior advantage of broad-caſting or drilling any particular crop, was never before ſo practicable; as the ſeed may now be put in with the utmoſt degree of regularity, in both methods of culture, by the ſame Machine; conſequently, the ſeed will be ſown in both caſes with equal accuracy, without which it is impoſſible to make a juſt deciſion.

The excellence of this Machine conſiſts in ſpreading any given quantity of ſeed over any given number of acres, with a mathematical exactneſs, which cannot be done by hand; by which a great ſaving may be made in ſeeding the ground, as well as benefiting the expected crop.

There has always been a difficulty in ſowing turnip ſeed with any degree of exactneſs, both from the minuteneſs of the ſeed, and the ſmallneſs of the quantity required to be ſown on an acre. Here the Machine has a manifeſt advantage, as it may be ſet to ſow the leaſt quantity ever required on an acre; and with an accuracy the beſt ſeedſman never can attain to.

It will alſo ſow clover, cole, flax, and every other kind of ſmall ſeed, with the utmoſt degree of regularity.

It will likewiſe broad-caſt beans, peaſe, and tares, or drill them with the greateſt exactneſs, particularly when conſtructed to be uſed with a Plough.

Another advantage attending the uſe of this Machine is, that the wind can have no effect on the falling of the ſeed.

Mr. Winlaw, of Margaret Street, Cavendiſh Square, having ermitted us to make drawings, and give deſcriptions, of ſeveral ew and improved Machines made by him for Agricultural pur-oſes, we preſent them to the public.

PLATE II. Fig. 1.

ESCRIPTION OF W. WINLAW's PATENT MILL, *made upon a Plan entirely new, for ſeparating the Grain from the Ears of Corn, in Place of Threſhing.*

"THIS Mill was tried in June, 1785, in the preſence of any gentlemen, and gave the greateſt ſatisfaction; and ſince hen to a great number of perſons at ſundry times, who all ex-reſſed great pleaſure at ſeeing a performance ſo compleat, and the achine conſtructed upon a plan entirely new.

"Upon trial there were paſſed through the Mill one buſhel of e heads of wheat in one minute, with very moderate labour to e man that turned it; and, by experiment, it is found that four uſhels of the ears will yield one buſhel of clean grain. This eing allowed, the difference will clearly appear betwixt the expe-ition of the Mill and the labour of a Threſher; allowing that a an will threſh ſix buſhels in a day, of eight hours work; the ill will clear that quantity in twenty-four minutes, and to an in-omparable greater degree of perfection than can poſſibly be done y the flail, for it ſeparates every grain from the ears, which muſt e allowed to be a very great ſaving; whereas much corn flies off y the flail, and a great deal loſt by foul threſhing, either when erformed by taſk or day-work; and by uſing the Mill all fraudu-ent practices will be prevented, the ſtraw is preſerved in its ori-inal reed, which muſt anſwer the eſſential purpoſes of thatching, c. much better than when bruiſed under the flail, and every other urpoſe equally well.

"The IMPROVED COMB for ſtripping the ears from the raw has been tried; and a lad, without having practiſed, combed ut a buſhel of ears in twenty minutes, which is at the rate of ſix uſhels of clean corn for one day's work.

"It requires very little practice to enable any perſon to manage the Mill. The dart painted on the fly directs which way to turn the handle, it being pointed as it ſhould be turned. The hopper, which ſerves to feed the Mill, is regulated by the two round pins, to which the cords are fixed. The ſcrew at the bottom of the frame is to adjuſt the diſtance of the inner nut from the outward cone; for if it is ſcrewed up too much it will bruiſe the grain, if lowered down too far it will admit the ears to paſs without effect. The croſs bars, which ſupport the axis on which the fly and pinion are fixed, are moveable upwards and downwards, as occaſion requires. When the ſcrew at bottom is turned to the right, it moves the nut upwards, and gives leſs ſpace. The wedges muſt be ſlackened above, to admit the axle to riſe upward or downward as may be found neceſſary. Theſe wedges may be ſlackened or tightened with great eaſe, and without any danger of injuring the Mill.

REFERENCES to Plate II. *fig.* 1.

A A A A, the Frame of the Mill.
B, the outward Cone.
C, the large Iron Wheel.
D, the Regulating Screw.
E, the Pinion.
G, the top Curb ſurrounding the Nut.
H, the Fly.
I, the Comb for ſtripping the Ears.

DIRECTIONS *for combing the Bottom of the Sheaves, and ſtripping the Ears from the Straw.*

"THE teeth or prongs of the Combs are made of ſteel, and of an angular form, ſet at ſuch convenient diſtances ſo as to ſtrip the ears clean; if ſet too wide apart they will paſs through without effect, and if too near together will not admit the ſtraw to go between.

"The Mill, upon a ſmaller ſcale, anſwers equally well for clover ſeed, the flowers being firſt threſhed off from the ſtems, it will clear as much ſeed from the outward integument or huſk in three hours as a man can perform, in the common mode of threſhing, in one week; for a man cannot clean much above a buſhel in that time. The tedioufneſs of the operation is an evident reaſon why the ſeed bears ſo high a price; the barn floors are likewiſe quickly deſtroyed by that tedious forcible performance. It alſo anſwers for flax ſeed, canary, or any other ſmall ſeeds; alſo for ſeparating the huſks from rice, which, by the preſent method in practice, is performed at a great expence of time and hard labour. The ſame methods may be obſerved in regulating the ſmall one for clover ſeed, as the Corn Mill."

How far this Threſhing Mill may be capable of ſeparating grain from the heads of wheat we will not pretend to determine, but we think it admirably calculated to threſh clover ſeed, after the heads are beat from the ſtraw; this being an operation ſo tedious and expenſive, a machine on a ſimple conſtruction to render the buſineſs more eaſy and expeditious has long been wiſhed for. Having ſeen this machine at work, we are firmly perſuaded it is a great acquiſition to thoſe who grow clover ſeed; we alſo ſaw it tried in milling, or ſeparating the huſks from trefoil, which it effected both complete and expeditious.

An ENGINE *for cutting* STRAW *for Cattle; alſo* SUGAR CANE TOPS, *&c. which renders it very uſeful for the Sugar Plantations, as well as the Purpoſes of Huſbandry.*

"THIS Machine has given entire ſatisfaction, being ſo contrived that it requires no practice to make any perſon perfect in working it, as the whole operation is performed by turning a winch, and can be made to cut the ſtraw to any length required.

"I have lately improved this uſeful Machine, and the great demand, both at home and abroad, ſufficiently proves its utility and benefit to the purchaſer."

DIRECTIONS *how to uſe the Chaff Engine.*

Put no more ſtraw in the box at once than will be about two inches and a half thick at the front end, where the two knives are placed. When the ſtraw is within two feet of being worked out, put in a fit quantity of freſh ſtraw, for it is attended with more trouble to put it under the preſſing board, after the ſtraw has been wholly worked out. Obſerve the ſliding rack that moves forward by the turning the handle; when it is worked up to the end of the box, unhook the turn-buckle, lift up the rack and move it back to the extent of the grooves, which are cut in the hinged board in the inſide of the box, and turn the hooked catch into its place again. Its only uſe is to keep the rack in the worm below, that moves it forward."

IS a front view of the Machine, diſplaying its mechanical principles.

A, A. Fly of caſt iron.

B. B. Knives annexed to the fly with ſcrews.
C. Pulley wheel to which an iron weight is ſuſpended by a chain.
D. Iron weight which compreſſes the ſtraw at the inſtant it is cut by the knife.
E. Screw or worm which brings forward the ſtraw, this in the Machine is in a right line with the ſpindle of the windlas, but is here elevated to diſplay its action.
F. Handle or windlas by which the fly is turned, and the operation performed.
G. Guard to prevent accidents as the fly revolves.
H. Frame to ſupport the whole.

Plate II. *Fig.* 3. Is a profile view of the ſame.

A. Box, or Hopper, containing the ſliding rack which holds the ſtraw.
B. Sliding rack.
C. Pulley wheel.
D. Chain going round the wheel and faſtened to the weight.
E. A ſhort projecting iron, which being touched by another, as the fly and knives reſolve, raiſes the weight and gives permiſſion to the ſtraw to be brought forward.

As the cutting chaff for cattle is a circumſtance of the moſt material conſequence, and the common method being very laborious, we think this invention will greatly facilitate the operation; and that a ſtrong boy may, with eaſe, do as much work with this Machine as two men can in the common method.

BRUISING ENGINE FOR MALT, *inſtead of the common Method of Grinding, likewiſe for Beans and other Grain for Horſes and other Cattle.*

" As Horſes ſwallow great part of the corn given them, whole or without chewing, and which often paſſes through them in the ſame ſtate; this being the caſe, they cannot receive any nouriſhment from the grains that are unbroke; but when bruiſed in this Machine, it eaſes maſtication, and every grain is prepared for nutrition, conſequently a much leſs quantity will be found ſufficient for cattle.

" This Machine is equally uſeful for bruiſing Malt. By repeated experiments it has been found, that Malt bruiſed is more advantageous than the common method of grinding and flouring, by which a great part is waſted. It is a great deal more expeditious than the common method, and is by no means liable to be out of repair."

DIRECTIONS *how to uſe the above Engine.*

" To bruiſe oats, ſcrew the large roller cloſe up to the ſmall one, and do not feed too faſt from the ſhoe, which you regulate by the pins which have ſtrings fixed to them. When you bruiſe Beans, unſcrew the two regulating ſcrews a little, and put the fly in motion with your hand, on account that the rollers are then a little ſpace apart, and will not turn each other before the Beans come between them. Feed ſlow and regular at firſt, until you have a little practice, oil the pivets frequently, or the iron will cut the coupling braſſes, and damage the mill."

Of the ſuperiority of Bruiſing Malt in preference to grinding it, we can from experience give ample teſtimony, when two ſmooth ſurfaces are oppoſed to each other at a diſtance which can be regulated at pleaſure; neither grain nor any other ſubſtance of a like nature, can paſs between them without being flattened or bruiſed. This being the principle on which the bruiſing mill acts the mealy ſubſtance, which is the eſſential part of Malt, is entirely removed from the ſkin or huſk which contains it, and all the virtues of the Malt are with eaſe extracted by the water, in a manner ſuperior to Malt which is cut to pieces by grinding. We attentively examined this machine, and Mr. WINLAW, at our requeſt, procured a buſhel of malt, purpoſely to exhibit the perfections of his machine; and we were witneſs that two men, with eaſe, bruiſed a buſhel of malt in one minute, and believe there was not a ſingle grain eſcaped whole.

MACHINE FOR DRESSING CORN, RAPE-SEED, FLAX-SEED, MUSTARD-SEED, &c.

" THIS Machine winnows, riddles, and ſcreens, all at one operation, and will finiſh after the threſher, between twenty and thirty buſhels in one hour; and will dreſs in the granary ten quarters in the hour.

" The three principal performances of this Machine are,
I. That it dreſſes better than any other method.
II. With leſs waſte; and
III. More expeditiouſly than any other method yet found out; and has been proved by a great many gentlemen, corn-merchants and farmers.

" It gives corn an additional brightneſs, by paſſing through wire riddles and ſcreens, both fixed and moving; and the benefit in a granary is, that it cleans the corn from duſt, which breeds weevils; and blows them out if any be in. The above Machine will dreſs malt better than any other method yet found out, and much quicker."

In uſing this Winnowing Machine three perſons are neceſſary; one to ſupply the hopper, another to turn the handle which gives motion to the Machine, and a third to remove the grain from the bottom of the ſcreen.

In Yorkſhire, and other parts of the north, theſe implements are generally uſed, and with the greateſt ſucceſs; and as the conſtruction is ſimple, and the performance expeditious, we think the invention of great utility. Thoſe made by Mr. WINLAW are on a better principle than any other we have ſeen, and make no doubt they are much improved by his ingenuity.

REFERENCE to the Winnowing Machine, Plate II. *Fig.* 5.

A. Body of the Machine in which are the fan, riddle, and ſcreen.
B. Hopper, where the Machine is ſupplied.
C. Wheel which gives motion to the work, the windlas being on the oppoſite ſide on the ſame ſpindle.
D. Pulley-wheel that moves the fan, ſcreen, and riddle.
E. Crank-rod faſtened to the riddle and ſcreen, and gives them motion.
F. Chain going round each wheel in a groove.
G. Four ſhort handles to convey it from place to place by two men.
H. Feet or ſupporters.
I. Fan made of wood which blows chaff from the corn.
K. Riddle which ſtops ſtraw, the heads of corn, and other matters.
L. Cloſe ſcreen, by which the corn is perfectly cleaned.

A MACHINE *on a ſimple Conſtruction to cut* TURNIPS, POTATOES, CARROTS, *or* CABBAGE, *before they are given to Cattle.*

THIS Machine will cut into pieces of any ſize, according to the pleaſure of the perſon who uſes it, as many roots and other ſuch kind of ſubſtances in one minute, by the turning of a wheel, as by the common method would employ a perſon one hour. It is perfectly ſimple in its operation and make, and compoſed of very few movements, of courſe not liable to be out of repair.

REFERENCE to the Turnip-Cutter, Plate II. *Fig.* 6.

A. Hopper, into which the roots or cabbages are put.
B. Fly-wheel, which by a windlas gives motion to the Machine.
C. Handle or windlas.
D. Lower part of the wheel, which is armed with four knives ſet narrow or wide by means of ſcrews.
E. Frame.
F. Cutting-wheel exhibited independent of the Machine, and which contains the knives mentioned as above.

REMARK.

AS we, for reaſons before given, now conclude this part of our SYSTEM OF AGRICULTURE, gratitude obliges us to return our ſincere thanks to thoſe whoſe kindneſs we have experienced; our endeavours have been to render ſervice to the art; if we have ſucceeded in any reſpect, the thoughts of having added, in the ſmalleſt degree, to ſo important a ſubject, is a ſufficient reward.

Variety of other detached matters relating to Agriculture, will be regularly claſſed under the article HUSBANDRY, and Plates given of every implement, new or old, which we conceive uſeful.

If the AUTHOR of this Syſtem has beſtowed cenſure on any gentleman undeſervedly, he will readily acknowledge his faults, and as he conceives anonymous attacks on real characters illiberal, Mr. COOKE, the publiſher, has liberty to give his addreſs.

AGRIFOLIUM, in botany, the Holy tree.

AGRIMONIA, Agrimony: a genus of the digynia order, belonging to the dodecandria claſs of plants; and in the natural method ranking under the 35th order, Senticoſæ. For its characters, ſee Syſtem of Botany. Of this genus there are five ſpecies enumerated by botanical writers; but none of them have any remarkable properties except the two following:

1. The eupatoria, or common agrimony, grows naturally in ſeveral parts of Britain by the ſides of hedges and of woods. It is eat by ſheep and goats, but refuſed by horſes and ſwine.

2. The odorata, or ſweet-ſcented agrimony. This grows near four feet high; the leaves have more pinnæ than the former; the ſerratures of the leaves are alſo ſharper, and, when handled, they emit an agreeable odour.

Both theſe ſpecies may be propagated either by ſeed, or by parting the roots in autumn when the leaves begin to decay. The ſeeds ought alſo to be ſown in this ſeaſon; for if kept out of the ground till ſpring, they ſeldom come up that year. Agrimony is a hardy perennial plant, and will thrive in almoſt any ſoil or ſituation; but the plants ſhould not be placed nearer one another than two feet, that the roots may have room to ſpread.

AGRIOCARDAMUM, ſynonimous with cardamine.

AGRIOCASTANUM, ſignifying the earth nut, commonly called the pig nut.

AGRIOCINARA, in botany, ſignifies a ſpecies of the wild articnoak.

AGRIOCOCCIMELA, or Prunus Sylvestris, the plum trees.

AGRIOMELA, ſignifies the crab-apple, or crab-tree.

AGRIOMELANZANION, amongſt the ancient botaniſts, implied a kind of eſculent night ſhade, or ſolanum.

AGRIONA, in Grecian antiquity, feſtivals annually celebrated, by the Bœotians, in honour of Bacchus. At theſe feſtivals the women pretended to ſearch after Bacchus as a fugitive; and, after ſome time, gave over their inquiry, ſaying, that he was fled to the Muſes, and was concealed among them.

AGRIOPHAGI, in antiquity, a name given to thoſe who fed on wild beaſts. The word is Greek compounded of *αγριος*, "wild," "ſavage," and *Φαγω*, "I eat." The name is given, by ancient writers, to certain people, real or fabulous, ſaid to have fed altogether on lions and panthers. Pliny and Solinus ſpeak of Agriophagi in Ethiopia, and Ptolemy of others in India on this ſide the Ganges.

AGRIORIGANUM, in botany, ſignifies wild marjoram.

AGRIOSELINUM, in botany, ſignifies wild parſley.

AGRIPPA, in midwifery, a term applied to children, brought forth with their feet foremoſt.

AGRIPPINIANS, in church hiſtory, the followers of Agrippinus biſhop of Carthage, in the third century, who firſt introduced and defended the practice of re-baptization.

AGRIUM, in the materia medica of the ancients, ſignified the impurer ſort of natrum.

AGROM, a diſeaſe frequent in Bengal and other parts of the Indies, wherein the tongue chaps and cleaves in ſeveral places, being extremely rough withal, and ſometimes covered with white ſpots. The Indians are very fearful of this diſeaſe, which they attribute to extreme heat of the ſtomach. Their remedy is to drink ſome chalybeate liquor, or the juice of mint.

AGROSTEMA, Wild Lychnis, or Campion: a genus of the pentagynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 22d order, Caryophyllei. For the characters, ſee Syſtem of Botany.

The moſt remarkable are, 1. The githago, hairy wild lychnis, or common campion, which grows naturally in corn fields in moſt parts of Britain. The flowers appear in June, are generally purple, ſometimes white, and by cultivation yellow.

2. The coronaria, or ſingle-roſe campion. Of this ſpecies there are four varieties; one with deep red, another with fleſh-coloured, a third with white, flowers; and a ſort with double flowers, which has turned moſt of the others out of the gardens.

3. The flos jovis, or umbelliferous mountain-campion, grows naturally upon the Helvetian mountains. It is a low plant with wooly leaves: the flower-ſtem riſes near a foot high; the flowers grow in umbels on the top of the ſtalk, and are of a bright red colour. They appear in July, and the ſeeds ripen in September.

The firſt and third ſpecies are annual plants, ſo muſt be propagated by ſeeds. The ſecond ſpecies is perennial, but only thoſe varieties which have ſingle flowers produce any ſeeds; the double kind, therefore, as it produces no ſeeds, muſt be propagated by parting the roots in autumn, after the flowers are paſt. This plant is eat by horſes, goats, and ſheep.

AGROSTIS, Bent-grass, in botany: a genus of the triandria order, belonging to the digynia claſs of plants; and, in the natural method, ranking under the 4th order, Gramina. For its characters, ſee Syſtem of Botany. There are 15 ſpecies; eight of them natives of Britain.

AGROSTOGRAPHIA, in phyſiology, ſignifies the hiſtory or deſcription of graſſes.

AGROUND, the ſituation of a ſhip whoſe bottom, or any part of it, hangs or reſts upon the ground, ſo as to render her immoveable, till a greater quantity of water floats her off, or till ſhe is drawn out into the ſtream by the application of mechanical powers.

AGRYPNIA, among phyſicians, implies an inaptitude to ſleep; a troubleſome ſymptom of feveriſh and other diſorders.

Agrypnia, in the Greek church, implies the vigil of any of the greater feſtivals.

AGUAGUIN, in Botany, a ſhrub in much eſteem among the Africans, as balſamic and vulnerary. See Philoſophical Tranſactions, No. 232.

AGUAPECACA, in ornithology, a Brazilian bird of the moor-hen kind.

AGUARA-QUIYA, in botany, a Brazilian plant, ſomewhat ſimilar to the common nightſhade.

AGUARA-PONDA, in botany, the plant called the Viola Spicata Braziliana.

AGUE, a general name for all periodical fevers, which, according to the different times of the returns of the feveriſh paroxyſm, are denominated tertian, quartian and quotidian.

Ague-Cake, the popular name for a hard tumour on the left ſide of the belly, ſaid to be the effect of intermitting fevers.

Ague-Tree, a name given by ſome to the ſaſſafras, on account of its febrifuge qualities.

AGUILLANEUF, or Augillaneuf, a form of rejoicing uſed among the antient Franks on the firſt day of the year. The word is compounded of the French *A* "to," *gui*, "miſleto," and *l'an neuf*, "the new year." Its origin is traced from a druid ceremony: the prieſts uſed to go early in December, which with them was reputed a ſacred month, to gather miſleto from the oak in great ſolemnity. The prophets marched in the front, ſinging hymns in honour of their deities; after them came an herald with a caduceus in his hand; theſe were followed by three druids abreaſt, bearing the things neceſſary for ſacrifice; laſt of all came the chief, or arch-druid, accompanied with the train of people. The chief druid climbing the oak, cut off the miſleto with a golden ſickle, and the other druids received it in a white cloth: on the firſt day of the year it was diſtributed among the people, after having bleſſed and conſecrated it by crying, *A gui l'an neuf*, to proclaim the new year. This cry is ſtill continued in Picardy, with the addition of *Plantez, Plantez*, to wiſh a plentiful year. In Burgundy, and ſome other parts, the children uſe the ſame word to beg a new-year's gift. Of later times the name *Aguillaneuf* was alſo given to a ſort of begging, practiſed in ſome dioceſes, for church tapers, on new-year's day, by a troop of young people of both ſexes, having a chief, &c. It was attended with various ridiculous ceremonies, as dancing in the church, &c. which occaſioned the ſynods to ſuppreſs it.

AGUILLES, cotton cloth made at the Turkiſh factory at Aleppo.

AGUL, in botany, a ſmall prickly ſhrub, whoſe leaves are longiſh, and reſemble thoſe of the knot-graſs. It abounds with flowers of a reddiſh colour, which are ſucceeded by red huſks. This plant grows in Arabia, Perſia and Meſopotamia.

AGURAH, in Jewiſh antiquity, the name of a ſilver coin to the value of a twentieth part of an antient ſilver ſhekel.

AGUSADURA, in ancient cuſtoms, a fee due from vaſſals to their lord for ſharpening their ploughing tackle. Anciently the tenants in ſome manors were not allowed to have their rural implements ſharpened by any but whom the lord appointed; for which an acknowledgment was to be paid, called *Aguſadura*, in ſome places *Aguſage*; which ſome take to be the ſame with what was otherwiſe called *Reillage*, from the ancient French *reille*, a ploughſhare.

AGUTI, in zoology, the name of an American animal of the rat ſpecie, much reſembling what is called in England the Guinea-pig. It has the characters of the rat, with the voice and hair of a hog. It is a very voracious animal, devouring its food with extreme eagerneſs, and uſing its fore feet in the manner of the ſquirrel. It runs very ſwiftly, and is amazing expert at digging, ſo that it ſoon buries itſelf in the earth. When provoked, it raiſes all the hair of its back upright, and ſtrikes the earth with its hinder feet.

AGUTIGUEPA obi Brasiliensibus, in medicine, the name given by many authors to the arrow-root, or ſagittaria-alexipharmica of the Weſt Indies.

AGYEI, in antiquity, a kind of obeliſks ſacred to Apollo, erected in the veſtibules of houſes, by way of ſecurity.

AGYNIANI, in church hiſtory, a ſect who condemned all uſe of fleſh, and marriage, as not inſtituted by God, but introduced at the inſtigation of the devil. The word is compounded of the privative *α*, and *γυνη*, *woman*. They are ſometimes alſo called *Agynnenſes*, and *Agynii*; and are ſaid to have appeared about the year 694. It is no wonder they were of no long continuance. Their tenets coincide in a great meaſure with thoſe of the Abelians, Gnoſtics, Cerdonians, and other preachers of chaſtity and abſtinence.

AGYRTÆ, in antiquity, a kind of ſtrolling impoſtors running about the country, to pick up money by telling fortunes at rich men[illegible] doors, pretending to cure diſeaſes by charms, ſacrifices, and other religious myſteries; alſo to expiate the crimes of their deceaſed anceſtors, by virtue of certain odours and fumigations; to torment their enemies, by the uſe of magical verſes and the like. The word is Greek Αγυρται, formed of the verb *αγυρω, I congregate*; alluding to the practice of quacks, who gather a crowd about them.

Agyrtæ, among the Greeks, ſignify the ſame with *Æruſcatores* among the Latins, and differs not much from Gypſies among us.

AHALOTH, in the materia medica, a Hebrew name given to the lignum aloes, or aloes wood.

AHANIGER, in ichthyology, a name given by Albertus, and by others called the acus vulgaris, or garfiſh.

AHÆTULA, the trivial name of a ſpecies of the coluber.

A-HEAD, a ſea-term, ſignifying further onward than the ſhip, or at any diſtance before her, lying immediately on that point of the compaſs to which her ſtem is directed. It is uſed in oppoſition to aſtern, which expreſſes the ſituation of an object behind the ſhip.

AHICCYATLI, in zoology, the Indian name of a ſerpent reſembling the rattle-ſnake, only it wants the rattles. It is as fatal in the effect of its poiſon as any known ſpecies of ſerpent.

AHMELLA, in botany, a ſpecies of bidens or water hemp agrimony.

AHOUAI, in botany, a ſynonime, and alſo the trivial name of a ſpecies of Cerbera.

A-HULL, in the ſea-language, the ſituation of a ſhip when all her ſails are furled on account of the violence of the ſtorm, and when having laſhed her helm on the lee-ſide, ſhe lies nearly with her ſide to the wind and ſea, her head being ſomewhat inclined to the direction of the wind.

AIAIA, in ornithology, a ſpecies of the ſpoon-bill in Brazil, South America.

AJAX, in antiquity, a furious kind of dance, in uſe among the Grecians; intended to repreſent the madneſs of that hero after his defeat by Ulyſſes, to whom the Greeks had given the preference in his conteſt for Achilles's arms. Lucian, in his treatiſe on Dancing, ſpeaks of dancing the Ajax. There was alſo an annual feaſt called Ajantia, Αιαντεια, conſecrated to that prince, and obſerved with great ſolemnity in the iſland of Salamis, as well as in Attica; where, in memory of the valour of Ajax, a bier was expoſed, ſet out with a compleat ſet of armour.

AICUROUS, a ſpecies of parrot.

AID, in a general ſenſe, denotes any kind of aſſiſtance given by one perſon to another.

Aid, in law, denotes a petition made in court to call in help from another perſon who has intereſt in land, or any other thing conteſted.

Aid-de-camp, in military affairs, an officer employed to receive and carry the orders of a general.

Aid, Auxilium, in antient cuſtoms, a ſubſidy paid by vaſſals to their lords on certain occaſions. Such were the aid of relief, paid upon the death of the lord meſne to his heir; the *aid cheval*, or capital aid, due to the chief lord on ſeveral occaſions, as, to make his eldeſt ſon a knight, to make up a portion for marrying his daughter, &c.

AIDS, in the French cuſtoms, certain duties paid on all goods exported or imported into that kingdom.

Court of aids, in France, a ſovereign court eſtabliſhed in ſeveral cities, which has cognizance of all cauſes relating to the taxes, gabelles, and aids, impoſed on ſeveral ſorts of commodities, eſpecially wine.

Aids, in the manege, are the ſame with what ſome writers call *cheriſhings*, and uſed to avoid the neceſſity of corrections. The inner heel, inner leg, inner rein, &c. are called *inner aids*; as the outer heel, outer leg, outer rein, &c. are called *outer aids*.

AIEREBA, in ichthyology, a ſpecies of the paſtinacha marina kind of fiſh.

AIGEIROS, ſignifies the black poplar.

AIGHENDALE, the name of a liquid meaſure uſed in Lancaſhire, containing ſeven quarts.

AIGITHALUS, αιγιθαλος, in ornithology, the little hedge bird, called the tom-tit-mouſe.

AIGRETTA, in ornithology, a name given to a ſpecies of the heron.

AIGUISCE, in heraldry, denotes a croſs with its four ends ſharpened, but ſo as to terminate in obtuſe angles. It differs from the croſs fitchee, inaſmuch as the latter tapers by degrees to a point, and the former only at the ends.

AILE, in law, a writ which lies where a perſon's grandfather, or great-grandfather, being ſeiſed of lands, &c. in fee-ſimple, the day that he died, and a ſtranger abates and enters the ſame day, and diſpoſſeſſes the heir of his inheritance.

AILERONS, in natural hiſtory, the fleſhy part of the wings of flies.

AILES vitrees, in natural hiſtory, a French term uſed to expreſs the wings of a ſeries of inſects between the fly and butterfly kind.

AIPIMIXIRA, in ichthyology, the name of an American fiſh, called the pudiano. It is a ſmall fiſh about the ſize of a perch, with a purple back, and yellow ſides and belly.

AIR, in natural philoſophy, a thin, fluid, elaſtic, tranſparent, ponderous, compreſſible, and dilatable body, ſurrounding the terraqueous globe to a conſiderable height.

Air, in medicine, &c. makes one of the ſix non-naturals. From obſervations on bleeding in rheumatiſms, and after taking cold, it is evident, the air can enter with all its qualities, and vitiate the whole texture of the blood, and other juices. From the palſies, vertigoes, and other nervous affections cauſed by damps, mines, &c. it is evident, that air thus qualified can relax and obſtruct the whole nervous ſyſtem. And from the cholics, fluxes, coughs, and conſumptions produced by damp, moiſt, and nitrous air, it is evident it can corrupt and ſpoil the noble organs, &c.

Circulation of Air *in Rooms.* To render the circulation of air ſenſible, let the air of a room be heated by a ſtrong fire, whilſt the air of a contiguous room is cold; then let the door between theſe two rooms be opened, in which caſe the hot air of one room being lighter, will paſs through the upper part of the opening of the door into the cold room; and, on the contrary, the cold air of the other room being heavier, will paſs into the former room through the lower part of the opening; accordingly, it will be found, that applying a lighted candle at the top, in the middle, and at the lower part of the opening between the two rooms, a ſtrong current of air will appear to paſs from the hot into the cold room near the top; a contrary current of air will appear to paſs from the latter into the former room near the lower part of the ſaid opening; whilſt in the middle there is little or no motion at all, as may be clearly perceived by the direction of the flame of the candle.

It is for the ſame reaſon, that when the fire is lighted in the chimney, a ſtrong current of air is occaſioned to enter the room, which may be felt by applying the hand near the key-hole, or other ſuch ſmall openings, if the doors and windows are ſhut; for the air over the fire being heated, becomes lighter, and aſcends into the chimney, conſequently other colder air muſt ſupply its place, which forces its way through all the ſmall openings it can find. Were a room with a fire in it to be perfectly cloſed, excepting the chimney, the air in it would ſoon become unwholeſome for reſpiration, and the fire would be ſoon extinguiſhed, beſides other inconveniences. Hence it appears, that thoſe perſons miſtake who expect to keep the air of a room ſweet and wholeſome, eſpecially for convaleſcents, by accurately ſtopping all the ſmalleſt openings that admit freſh air. When the current of air that enters into a room is on ſome ſide of it where it falls immediately upon the perſons who ſit in the room, then it may be offenſive, eſpecially to delicate conſtitutions. In that caſe, ſuch opening ſhould be cloſed: but at the ſame time another opening ſhould be made for admitting freſh air, in another more convenient part; for a circulation of air, eſpecially in rooms where a fire is kept, is not only ſalutary and uſeful, but abſolutely neceſſary.

In an ingenious publication, intitled, *A Practical Treatiſe on Chimnies*, there are the following remarks relating to the propereſt method of admitting air into a room, and of expelling the contaminated air. The author, directing to make a vent-hole near the top of the room, in order to expel the heated and contaminated air, "this," ſays he, "might be done by means of a ſmall tube opening into the room, either in or near the ceiling; which might either be carried to the top of the building, or be made to communicate with the external air by a ſmall perſpiration through the wall at the roof of the room; by means either of which, a proper circulation would be eſtabliſhed, and the foul air be carried off.

"For the fire would no ſooner have warmed any particles of air within the room, than theſe would be greatly expanded, and riſe immediately upwards, ſo as to fill the higher parts of the room with rarefied air? and as other particles would be ſucceſſively heated and rarefied in their turn, by their expanſive force they would preſs upon the ſides of the apartment in every place, ſo as to force the lighteſt particles through the opening left for that purpoſe in the top of the room; by which means the fouleſt air would be gradually drawn off, without deſcending again into the lower regions, to the annoyance of the company."

But in order to admit freſh air into the room, "Let," ſays he, "another opening be made in the ceiling of the room, having a communication with a ſmall pipe that ſhould lead from thence either to the outſide of the wall, or to any other part of the building that might be judged more convenient, where it ſhould be bent, and conducted downwards, till it reached the ground; where it ſhould be left open, to communicate with the external air. In this ſituation the cool external air would be forced in at the lower opening of the tube, and made to aſcend into the apartment in proportion to the quantity that eſcaped towards the higher regions by means of the ventilator. And as that weighty air would no ſooner enter the room, than it would tend towards the floor by its own natural gravity, it would gradually mix with the heated air in its deſcent, become, in ſome meaſure, warmed by that means, and equally diſperſed through the room, ſo as ſlowly and imperceptibly to reach the candles and the company in the room, and ſupply them with a ſufficient quantity of freſh and wholeſome air, without the inconveniences to which the company are ſubjected by the uſual way of admitting freſh air. For if it enters near the floor of the apartment, it is hurried along in a rapid undivided ſtream towards the fire-place, and ſtriking upon the legs and inferior parts of the body, affects them with a ſtrong ſenſation of cold. To overcome the effects of this, large fires muſt be kept, by which other parts of the body are warmed to an extraordinary degree, which is productive of moſt of thoſe diſorders that are pernicious to the young, and often prove fatal to the old, during the winter ſeaſon, in theſe cold regions.

"Thus might our apartments be kept conſtantly, moderately, and equally warm, at a moderate expence, without endangering our health on the one hand, by a reſpired confined, ſtagnant, and putrid air, or, on the other hand, by ſubjecting ourſelves to ſuch danger of catching colds, conſumptions, and rheumatic complaints, by being expoſed to ſuch exceedingly unequal degrees of heat and cold, as are unavoidable where our apartments are ſo open as to admit a ready paſſage to the external air during the winter ſeaſon.

"The reader will eaſily perceive, that all that has been here ſaid has a reference only to thoſe apartments in cold climates, and rigorous weather, where fire to warm them becomes neceſſary. In warmer regions, or during the ſummer ſeaſon, there can be no objection to the wheel-ventilator in the window. It is a ſimple contrivance, and a ſafe and effectual means of preſerving the air in our apartments ſweet and wholeſome at that ſeaſon."

It is a vulgar error among many people, to believe that fire purifies the contaminated air, by deſtroying the noxious particles mixed with it; and for this reaſon they think, that the fire kept in a room where the air is tainted, purifies the room, by rendering the air in it again fit for reſpiration. Indeed, a fire kept in a room or apartment where the air is tainted, as is the caſe with hoſpitals, goals, and the like, does certainly purify the apartment, and the practice is very uſeful; but this effect is only becauſe the fire promotes the circulation of the air, and dries the dampneſs of rooms, furniture, &c. ſo that it is not the infected air that is purified, but is new, freſh, and wholeſome air, that by the action of the fire has taken the place of the infected air; which infected air, being rarified by the heat, has been expelled from the apartment. Fire and combuſtion in general is ſo far from purifying contaminated air, that it actually contaminates a prodigious quantity of it in a ſhort time; ſo that not only a common fire, but even a lighted candle, when kept in a well-cloſed room, wherein the external air has not a free acceſs, inſtead of purifying, renders the air of that room noxious.

Air-Gun, a pneumatic machine for exploding bullets, &c. with great violence. See Syſtem of Pneumatics.

Air-Jacket, a ſort of jacket made of leather, in which are ſeveral bags, or bladders, compoſed of the ſame materials, communicating with each other. Theſe are filled with air through a leather tube, having a braſs ſtop-cock accurately ground at the extremity, by which means the air blown in through the tube is confined in the bladders. The jacket muſt be wet, before the air be blown into the bags, as otherwiſe it will immediately eſcape through the pores of the leather. By the help of theſe bladders which are placed near the breaſt, the perſon is ſupported in the water, without making the efforts uſed in ſwimming.

Air-Pipes, an invention for drawing foul air out of ſhips, or any other cloſe places, by means of fire. Theſe pipes were firſt found out by one Mr. Sutton, a brewer in London; and from him have got the name of Sutton's Air-pipes. The principle on which their operation depends is known to every body, being indeed no other than that air is neceſſary for the ſupport of fire; and, if it has not acceſs from the places moſt adjacent, will not fail to come from thoſe that are more remote. Thus, in a common furnace, the air enters through the aſh-hole; but if this is cloſed up, and a hole made in the ſide of the furnace, the air will ruſh in with great violence through that hole. If a tube of any length whatever is inſerted in this hole, the air will ruſh through the tube into the fire, and of conſequence there will be a continued circulation of air in that place where the extremity of the tube is laid. Mr. Sutton's contrivance then, as communicated to the Royal Society by Doctor Mead, amounts to no more than this. "As, in every ſhip of any bulk, there is always provided a copper or boiling-place proportionable to the ſize of the veſſel; it is propoſed to clear the bad air, by means of the fire already uſed under the ſaid coppers or boiling-places for the neceſſary uſes of the ſhip.

"It is well known, that, under every ſuch copper or boiler, there are placed two holes, ſeparated by a grate; the firſt of which is for the fires and the other for the aſhes falling from the ſame; and that there is alſo a flue from the fire-place upward, by which the ſmoke of the fire is diſcharged at ſome convenient place of the ſhip.

"It is alſo well known, that the fire once lighted in theſe fire-places, is only preſerved by the draught of air through the forementioned two holes and flue; and that if the ſaid two holes are cloſely ſtopped up, the fire, though burning ever ſo briſkly before, is immediately put out.

"But if, after ſhutting up the abovementioned holes, another hole be opened, communicating with any other room or airy place, and with the fire; it is clear, the ſaid fire muſt again be raiſed and burn as before, there being a like draught of air through the ſame as there was before the ſtopping up of the firſt holes; this caſe differing only from the former in this, that the air feeding the fire will now be ſupplied from another place.

"It is therefore propoſed, that, in order to clear the holds of ſhips of the bad air therein contained, the two holes abovementioned, the fire-place and aſh-place, be both cloſed up with ſubſtantial and tight iron-doors; and that a copper or leaden pipe, of ſufficient ſize, be laid from the hold into the aſh-place, for the draught of air to come in that way to feed the fire. And thus it ſeems plain, from what has been already ſaid, that there will be, from the hold, a conſtant diſcharge of the air then contained; and conſequently, that air, ſo diſcharged, muſt be as conſtantly ſupplied by freſh air down the hatches or ſuch other communications as are opened into the hold; whereby the ſame muſt be continually freſhened, and its air rendered more wholeſome and fit for reſpiration.

"And if into this principal pipe ſo laid into the hold, other pipes are let in, communicating reſpectively either with the [illegible] or lower decks; it muſt follow, that part of the air, conſumed in feeding the fire, muſt be reſpectively drawn out of all ſuch places to which the communication ſhall be ſo made."

This account is ſo plain, that no doubt can remain concerning the efficacy of the contrivance: it is evident, that, by means of pipes of this kind, a conſtant circulation of freſh air would be occaſioned through thoſe places where it otherwiſe be moſt apt to ſtagnate and putrefy. Several other contrivances have been uſed for the ſame purpoſe; and Doctor Hales's ventilators, by ſome unaccountable prejudice, have been reckoned ſuperior in efficacy and even ſimplicity to Mr. Sutton's machine, which at its firſt invention met with great oppoſition, and even when introduced by Dr. Mead, who uſed all his intereſt for that purpoſe, was ſhamefully neglected.

A machine capable of anſwering the ſame purpoſe was invented by M. Deſaguliers, which he called the *ſhip's lungs*. It conſiſted of a cylindrical box ſet up on its edge, and fixed to a wooden pedeſtal. From the upper edge of the box iſſued a ſquare trunk open at the end, and communicating with the cavity of the box. Within this box was placed a cylindrical wheel turning on an axis. It was divided into twelve parts, by means of partitions placed like the radii of a circle. Theſe partitions did not extend quite to the centre, but left an open ſpace of about eighteen inches diameter in the middle; towards the circumference, they extended as far as poſſible without interfering with the caſe, ſo that the wheel might always be allowed to turn freely. Things being thus circumſtanced, it is plain, that if the wheel was turned towards that ſide of the box on which the trunk was, every diviſion would puſh the air before it, and drive it out through the trunk, at the ſame time that freſh air would come in through the open ſpace at the centre, to ſupply that which was thrown out through the trunk. By turning the wheel ſwiftly, a ſtrong blaſt of air would be continually forced out through the ſquare trunk, on the ſame principles on which a common fanner winnows corn. If the wheel is turned the oppoſite way, a draught of air may be produced from the trunk to the centre. If this machine then is placed in a room where a circulation of air is wanted, and the trunk made to paſs through one of the walls; by turning the wheel ſwiftly round, the air will be forced with great velocity out of that room, at the ſame time that freſh air will enter through any chinks by which it can have acceſs to ſupply that which has been forced out.

It is evident, that the circulation which is promoted by this machine, is entirely of the ſame kind with that produced by Mr. Sutton's; the turning of the wheel in M. Deſagulier's machine being equivalent to the rarefaction of the air by fire in Mr. Sutton's; but that the latter is vaſtly ſuperior, as acting of itſelf, and without intermiſſion, requires no arguments to prove. Mr. Sutton's machine has yet another conveniency, of which no other contrivance for the ſame purpoſe can boaſt; namely, that it not only draws out putrid air, but deſtroys it by cauſing it to paſs through fire; and experience has abundantly ſhewn, that though putrid air is thrown into a great quantity of freſh air, it is ſo far from loſing its pernicious properties, that it often produces noxious diſeaſes. We do not ſay, indeed, that putrid air becomes ſalutary by this means; but it is undoubtedly rendered leſs noxious than before; though whether it is equally innocent with the ſmoke of a fire fed in the common way, we cannot pretend to determine.

Beſides this machine by M. Deſaguliers, the ventilators of Dr. Hales, already mentioned, and thoſe called *wind-ſails*, are likewiſe uſed for the ſame purpoſe; the former of which is an improvement of the Heſſian bellows: the other is a contrivance for throwing freſh air into thoſe places where putrid air is apt to lodge; but this has the laſt-mentioned inconvenience in a much greater degree than any of the others, as the blaſt of freſh air throws out that which was rendered putrid by ſtagnation, in ſuch a manner as to contaminate all around it.

Air-Trunk, is alſo a contrivance by Doctor Hales to prevent the ſtagnation of putrid effluvia in jails, and other places where a great number of people are crowded together in a ſmall ſpace. It conſiſts only of a long ſquare trunk open at both ends; one of which is inſerted into the ceiling of the room, the air of which is required to be kept pure; and the other extends a good way beyond the roof. Through this trunk a continued circulation is carried on: and the reaſon is, that the putrid effluvia which do ſo much miſchief when collected, being much lighter than the pure atmoſphere, ariſe to the top of the room; and, if they there find a vent, will continually go out through it. Theſe effluvia ariſe in very conſiderable quantities, being calculated by the late Dr. Keil at no leſs than 39 ounces from one man in twenty-four hours.

Theſe trunks were firſt made trial of by Mr Yeoman, over the Houſe of Commons, where they were [illegible] inches wide within; and over the Court of King's Bench, in Weſtminſter-Hall, where they were ſix inches wide. They are ſometimes made wider, and ſometimes narrower: but the wider they are, the longer they ought to be, more effectually to promote the aſcent of the vapour. The reaſon why vapours of this kind aſcend [illegible] ſwiftly through a long trunk than a ſhort one, is, that the preſſure of fluids is always according to their different depth, without regard to the diameter of their baſis, or of the veſſel which contains them; and, upon this principle, a gallon of water may be made to ſplit a ſtrong caſk. When the column of putrid effluvia is long and narrow, the difference between the column of atmoſphere preſſing on the upper end of the trunk, and that which preſſes on the lower end, is much greater than if the column of putrid effluvia was ſhort and wide; and conſequently the aſcent is much ſwifter. One pan of a ſingle pair of ſcales, which was two inches in diameter, being held within one of of theſe trunks over the Houſe of Commons, the force of the aſcending air made it riſe ſo as to require four grains to reſtore the equilibrium, and this when there was no perſon in the houſe; but when it was full, no leſs than twelve grains were requiſite to reſtore the equilibrium; which clearly ſhews, that theſe trunks muſt be of real and very great efficacy.

Air-Pump, a machine by which the air contained in a proper veſſel may be exhauſted or drawn out. See Syſtem of Pneumatics.

Air-Shafts, among miners, denote holes or ſhafts let down from the open air to meet the adits and furniſh freſh air. The damps, want, and impurity of air which occur, when adits are wrought 30 or 40 fathoms long, make it neceſſary to let down air-ſhafts, in order to give the air liberty to play through the whole work, and thus diſcharge bad vapours, and furniſh good air for reſpiration: the expence of which ſhafts, in regard of their vaſt depths, hardneſs of the rock, drawing of the water, &c. ſometimes equals, nay exceeds, the ordinary charge of the whole adit.

Sir Robert Murray deſcribes a method, uſed in the coal-mines at Liege, of working mines without air-ſhafts.

When the miners at Mendip have ſunk a groove, they will not be at the charge of an Air-ſhaft till they come at ore; and for the ſupply of air have boxes of elm exactly cloſed, of about ſix inches in the clear, by which they carry it down about twenty fathoms. They cut a trench at a little diſtance from the top of the groove, covering it with turf and rods diſpoſed to receive the pipe, which they contrive to come in ſideways to their groove, four feet from the top; which carries down the air to a great depth. When they come at ore, and need an air-ſhaft, they ſink it four or five fathoms diſtant, according to the convenience of the breadth, and of the ſame faſhion with the groove, to draw as well ore as air.

Air-Threads, in natural hiſtory, a name given the long filaments, ſo frequently ſeen in autumn, floating about in the air.

Theſe threads are the work of ſpiders, eſpecially of that ſpecies called the long-legged field-ſpider; which, having mounted to the ſummit of a buſh or tree, darts from its tail ſeveral of theſe threads, till one is produced capable of ſupporting the creature in the air: on this it mounts in queſt of prey, and frequently riſes to a very conſiderable height.

Air-Vessels, are ſpiral ducts in the leaves, &c. of plants, ſuppoſed to be analogous to the lungs of animals, in ſupplying the different parts of a plant with air.

Air, in mythology, was adored by the Heathens under the names of Jupiter and Juno; the former repreſenting the ſuperior and finer part of the atmoſphere, and the latter the inferior and groſſer part. The augurs alſo drew preſages from the clouds, thunder, lightning, &c.

Air, in painting, &c. denotes the manner and very life of action; or it is that which expreſſes the diſpoſition of the agent. It is ſometimes alſo uſed in a ſynonymous ſenſe with geſture or attitude.

Air, in muſic, is taken in different ſenſes. It is ſometimes contraſted with harmony; and, in this ſenſe, it is ſynonymous with melody in general. Its proper meaning is, a tune, which is ſet to words, or to ſhort pieces of poetry that are called *ſongs*.

In operas, we give the name of *air* to ſuch pieces of muſic as are formed with meaſures and cadences, to diſtinguiſh it from the recitative; and, in general, every piece of muſic is called an *air*, which is formed for the voice, or even for inſtruments, and adapted to ſtanzas, whether it forms a whole in itſelf, or whether it can be detached from any whole of which it forms a part, and be executed alone.

If the ſubject admits of harmony, and is ſet in parts, the *air* is, according to their number, denominated a *duet*, a *trio*, a *quartetto*, &c. We need not follow Rouſſeau, and the other philologiſts, in their endeavours to inveſtigate the etymon of the word *air*. Its derivation, though found and aſcertained, would contribute little to illuſtrate its meaning in that remote ſenſe, to which, through a long continuance of time, and the various viciſſitudes of language, it has now paſſed.

In modern muſic, there are ſeveral different kinds of *airs*, each of which agrees to a certain kind of dancing, and from theſe dances the airs themſelves take their ſpecific names.

The *airs* of our operas are, if we may be permitted the expreſſion, the canvaſs, or ſubſtratum, upon which are painted all the pictures of imitative muſic; melody is the deſign, and harmony the colouring; every pictureſque object ſelected from the moſt beautiful parts of nature, every reflected ſentiment of the human heart, are the models which the artiſt imitates; whatever gains attention, whatever intereſts the ſoul, whatever charms the ear, or cauſes emotion in the heart, theſe are the objects of his imitation. An air which delights the ear, and diſcovers the learning of the compoſer; an air invented by genius, and compoſed with taſte; is the nobleſt effort of muſic: it is this which explores the compaſs, and diſplays the delicacy, of a beautiful voice; it is in this where the charms of a well-conducted ſymphony ſhine; it is by this, that the paſſions, excited and inflamed by nice gradations, reach and agitate the ſoul through the avenues of external ſenſe. After hearing a beautiful *air*, the mind is acquieſcent and ſerene: the ear is ſatisfied, not diſguſted: it remains impreſſed on the fancy, it becomes a part of our eſſence, we carry it with us, we are able to repeat it at pleaſure: without the ability acquired by habit to breathe a ſingle note of it, we execute it in our imagination in the ſame manner as we heard it upon the theatre: one ſees the ſcene, the actor, the theatre; one hears the accompaniments and the applauſes. The real enthuſiaſt in muſic never forgets the beautiful airs which he has heard; when he chooſes, he cauſes the opera to re-commence.

The words to which *airs* are adapted, are not always rehearſed in regular ſucceſſion, nor ſpoken in the ſame manner with thoſe of the recitative; and though, for ordinary, they are very ſhort, yet they are interrupted, repeated, tranſpoſed, at the pleaſure of the artiſt. They do not conſtitute a narrative, which once told is over; they either delineate a picture, which it is neceſſary to contemplate in different points of view; or inſpire a ſentiment in which the heart acquieſces with pleaſure, and from which it is neither able or willing to be diſengaged; and the different phraſes of the *air* are nothing elſe but different manners of beholding the ſame image. This is the reaſon why the ſubject of an *air* ſhould be one. It is by theſe repetitions properly placed, it is by theſe redoubled efforts, that an impreſſion, which at firſt was not able to move you, at length ſhakes your ſoul, agitates you, tranſports you out of yourſelf: and it is likewiſe upon the ſame principle, that the runnings, as they are called, or thoſe long, mazy, and inarticulated inflections of the voice, which, in pathetic *airs*, frequently ſeem, though they are not always ſo, improperly placed; whilſt the heart is affected with a ſentiment exquiſitely moving, it often expreſſes its emotions by inarticulate ſounds, more ſtrongly and ſenſibly than it could do by words themſelves.

The form of *airs* is of two kinds. The ſmall airs are often compoſed of two ſtrains, which ought each of them to be ſung twice; but the important airs in operas are frequently in the form of rondeaus.

AIRA, in botany, a genus of the triandria digynia claſs; and in the natural method ranking under the 4th order, gramina. For the characters ſee Syſtem of Botany. There is no pericarpium; including corolla grows to the ſeed: the ſeed is egg-ſhaped and covered. There are fourteen ſpecies of the aira, nine of which are natives of Britain. The Engliſh name is Hair-graſs.

AIRING, a term peculiarly uſed for the exerciſing horſes in the open air. It purifies the blood; purges the body from groſs humours; and, as the jockies expreſs it, teaches the horſe how to make his wind rake equally, and keep time with the other motions of his body. It alſo ſharpens the ſtomach, and keeps the creatures hungry; which is a thing of great conſequence, as hunters and racers are very apt to have their ſtomachs fall off, either from want of exerciſe, or from the too violent exerciſe which they are often expoſed to. If the horſe be over fat, it is beſt to air him before ſun-riſe and after ſun-ſetting; and in general, it is allowed by all, that nothing is more beneficial to thoſe creatures than early and late airings. Some of our modern managers, however, diſpute this: they ſay, that the cold of theſe times is too great for the creature; and that if, in particular, he is ſubject to catarrhs, rheums, or the like complaints, the dews and cold fogs, in theſe early and late airings, will be apt to o increaſe all thoſe diſorders. Nature, we ſee, alſo points out he ſun-beams as of great uſe to theſe animals; thoſe which re kept hardy and lie out all night, always running to thoſe laces where the ſunſhine comes, as ſoon as it appears in a norning. This ſhould ſeem to recommend thoſe airings that re to be made before ſun-ſet, and a little time after ſun-riſe. As to the caution, ſo earneſtly inculcated by Markham, of uſing heſe early and late airings for fat horſes, it is found unneceſſary y many: for they ſay, that the ſame effect may be produced by irings at warmer times, provided only that they are made onger; and that, in general, it is from long airings we are to xpect to bring a horſe to a perfect wind and ſound courage.

AIRS, in the manege, are the artificial motions of taught orſes; as the demivolt, curvet, capriole, &c.

AIRY, or Aery, among ſportſmen, a term expreſſing the eſt of a hawk or eagle.

Airy Triplicity, among aſtrologers, denotes the three igns, gemini, libra, and aquarius.

AJUBATIPITA Braſilienſum, in botany, a name given o a ſhrub that bears a black fruit like an almond, which yields a reat deal of oil.

AJUGA, Bugle, a genus of the gymnoſpermia order, beonging to the didynamia claſs of plants; and in the natural nethod ranking under the 42d order, *Aſperifoliæ*. For the chaacters, ſee Syſtem of Botany. The ſpecies enumerated by innæus are, 1. The orientalis, with inverted flowers, which is native of the eaſt. 2. The genevenſis, a native of Swiſſerland. . The pyramidalis, or mountain-bugle, a native of Sweden, ermany, Swiſſerland, and the hilly parts of Europe, and is net with in woods and moiſt places in many parts of Britain. he roots are aſtringent, and ſtrike a black colour with vitriol f iron.

The firſt ſpecies is propagated by ſowing the ſeeds ſoon after hey are ripe, in a pot filled with loamy earth, and placed in a hady ſituation till autumn; when it muſt be removed under a rame, and protected from the froſts. In the ſpring, after the lants are come up, let them be tranſlated each into a ſeparate ot, and in ſummer placed under a ſhady ſituation. The other orts are eaſily propagated by their ſide-ſhoots, and ſucceed beſt n a moiſt ſhady ſituation.

AJURU Catinga, in ornithology, a ſpecies of parrot found n Brazil, South America.

Ajuru Curau, in ornithology, another ſort of Brazilian arrot of various colours.

Ajuru Para, in ornithology, a ſpecies of the ſmall Braſiian parrot.

AIUS Locutius, the name of a deity to whom the Romans rected an altar. The words are Latin, and ſignify "a ſpeaking oice." The following accident gave occaſion to the Romans recting an altar to the Aius Locutius. One M. Seditius, a lebeian, acquainted the tribunes, that, in walking the ſtreets y night, he had heard a voice over the temple of Veſta, giving he Romans notice that the Gauls were coming againſt them. This intimation was however neglected; but after the truth was onfirmed by the event, Camillus acknowledged this voice to e a new deity, and erected an altar to it under the name of the ius Locutius.

AJUTAGE, or Adjutage, a kind of tube fitted to the nouth of the veſſel through which the water of a fountain is to e played. To the different form and ſtructure of ajutages, is wing the great variety of fountains.

AIZOON, in botany, called by Mr. Miller *ſempervive*; hough the name Aizoon has been by ſome writers applied to the ouſe-leek, and alſo to the aloes: it is a genus of the pentaynia order, belonging to the icoſandria claſs of plants; and in he natural method ranking under the 13th order, Succulentæ. innæus mentions three ſpecies; the canarienſe, hiſpanicum, nd paniculatum. The firſt is a native of the Canary iſlands, he ſecond of Spain, and the third of the Cape of Good Hope. hey may all be raiſed in this country on hot-beds.

AKOND, an officer of juſtice in Perſia, who takes cogniance of the cauſes of orphans and widows; of contracts, and ther civil concerns. He is the head of the ſchool of law, and ives lectures to all the ſubaltern officers; he has his deputies in ll the courts of the kingdom, who, with the ſecond *ſadra*, nake all contracts.

AL, an Arabic particle prefixed to words, and ſignifying much e ſame with the Engliſh particle *the*: thus they ſay, alkermes, lkoran, &c. i. e. the kermes, the koran, &c.

Al, or Ald, a Saxon term frequently prefixed to the names f places, denoting their antiquity; as Aldborough, Aldgate, &c.

ALA, a Latin term properly ſignifying a wing; from a reemblance to which ſeveral other things are called by the ſame ame: Thus,

Ala, is a term uſed by botaniſts for the hollow of a ſtalk, which ther the leaf, or the pedicle of the leaf, makes with it; or it that hollow turning, or ſinus, placed between the ſtalk or ranch of a plant and the leaf, whence a new offſpring uſually ues. Sometimes it is uſed for thoſe parts of leaves, otherwiſe lled *lobes*, or *wings*.

ALÆ (the plural number) is uſed to ſignify thoſe petals or leaves of papilionaceous flowers, placed between thoſe others which are called the *vexillum* and *carina*, and which make the top and bottom of the flowers. Inſtances of flowers of this ſtructure are ſeen in thoſe of peaſe and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the ſide ones the alæ.

Alæ is alſo uſed for thoſe extremely ſlender and membranaceous expanſions running along the ſtems of ſome plants, which are therefore called *alated ſtalks*.

Alæ, in anatomy, a term applied to the lobes of the liver, the cartilages of the noſtril, &c.

Alæ, in the Roman art of war, were the two wings or extreme parts of the army drawn up in order of battle.

ALABARCHA, in antiquity, a kind of magiſtrate among the Jews of Alexandria, whom the emperors allowed them to elect, for the ſuperintendency of their policy, and to decide differences and diſputes which aroſe among them.

ALABARDA, the name of a ſpear, anciently uſed by the Helvetians and Germans.

ALABASTER, in natural hiſtory, a ſpecies of that genus of ſtones whoſe baſe is calcareous earth. It differs from marble in being combined, not with the aërial, but with vitriolic acid; therefore, when mixed with any acid, no efferveſcence appears. It is ſoluble in about 500 times its weight of water at the temperature of 60. It is fuſible alone in a long-continued porcelain heat, or by the blow-pipe. Specific gravity 1.87. Texture granular, with ſhining particles. In compoſition, and conſequently in its chemical properties, it does not differ from gypſum, ſelenite, and plaſter of Paris.

There are three ſpecies of alabaſter. 1. The ſnow-white ſhining alabaſter, or lygdinum of the ancients, is found in Taurus, in pieces large enough to make diſhes, or the like. It cuts very freely, and is capable of a fine poliſh. 2. The yellowiſh alabaſter, or phengites of Pliny, is found in Greece; and is of a ſoft looſe open texture, pretty heavy, and nearly of the colour of honey. This ſpecies has likewiſe been found in Germany, France, and in Derbyſhire in England. 3. Variegated, yellow, and reddiſh alabaſter. This ſpecies is the common alabaſter of the ancients, and is ſo ſoft that it may be cut with a knife: it is remarkably bright, and almoſt tranſparent; admits of a fine poliſh, and conſiſts of large angular ſparry concretions. It is not proof againſt water; it ferments violently with aqua-fortis, and burns to a pale yellow. The colour of this ſpecies is a clear pale yellow reſembling amber, and variegated with undulated veins; ſome of which are pale red, others whitiſh, and others of a pale brown. It was formerly brought from Egypt, but is now to be met with in ſeveral parts of England. The alabaſters are frequently uſed by ſtatuaries for ſmall ſtatues, vaſes, and columns. After being calcined and mixed with water, they may be caſt in any mould like plaſter of Paris.

Alabaster, in antiquity, a term uſed for a vaſe wherein odoriferous liquors were anciently put. The reaſon of the denomination is, that veſſels for this purpoſe were frequently made of the alabaſter-ſtone, which Pliny and other ancients repreſent as peculiarly proper for this purpoſe.

Alabaster is alſo ſaid to have been uſed for an ancient liquid meaſure, containing ten ounces of wine, or nine of oil. In this ſenſe, the alabaſter was equal to half the ſextary.

ALABASTRITÆ Alabastrites, in natural hiſtory, a ſpecies of alabaſter.

ALABASTRUM Dendroide, a kind of laminated alabaſter, beautifully variegated with the figures of ſhrubs, trees, &c. found in great abundance in the province of Hohenſtein.

ALADINISTS, a ſect among the Mahometans, anſwering to free-thinkers among us.

ALAMANNICUM, in antiquity, a tribute impoſed by the Roman emperor Alexius Angelus.

ALAMODALITY, in a general ſenſe, is the accommodating a perſon's behaviour, dreſs, and actions, to the prevailing taſte of the country or times in which he lives.

Alamodality *of Writing*, is defined the accommodation of mental productions, both as to the choice of ſubject and the manner of treating it, to the genius or taſte of the times, in order to render them more acceptable to the readers.

ALAMODE, a phraſe originally French, importing a thing to be in the faſhion or mode. The phraſe has been adopted not only into ſeveral of the living languages, as the Engliſh and High Dutch, but ſome have even taken it into the Latin. Hence we meet with *Alamodicus* and *Alamodalitas*.

Alamode, in commerce, a thin gloſſy black ſilk, chiefly uſed for womens hoods and mens mourning ſcarfs.

ALANA-Gibea, a name given to the yellowiſh white tripoli.

ALANA-Terra, ſignifies a drying aſtringent, uſed in diſtillation, commonly known by the name of Engliſh oker.

ALANFUTA, ſignifies in the Perſian art of phyſic, to bleed between the chin and the under lip, to cure a foul breath.

ALANORARIUS, in antiquity, implies a ſportſman, or keeper of game dogs.

ALAPOULI, in phyſioligy, implies a ſpecies of the Eaſt Indian medicinal tree called bilimbi.

ALAQUECA, an Indian medicinal ſtone, ſaid to be good againſt hemorrhages, when applied internally.

ALARAF, in the Mahometan theology, the partition wall that ſeparates heaven from hell. The word is plural, and properly written *al araf*; in the ſingular it is written *al arf*. It is derived from the Arabic verb *arafa*, to diſtinguiſh. Al araf gives the denomination to the ſeventh chapter of the alcoran, wherein is made mention of this wall. Mahomet ſeems to have copied his Al araf, either from the great gulph of ſeparation mentioned in the New Teſtament, or from the Jewiſh writers, who alſo ſpeak of a thin wall dividing heaven from hell. Mahometan writers differ extremely as to the perſons who are to be found on Al araf. Some take it for a ſort of limbus for the patriarchs, prophets, &c. others place here ſuch whoſe good and evil works ſo exactly balance each other, that they deſerve neither reward or puniſhment. Others imagine this intermediate ſpace to be poſſeſſed by thoſe who, going to war without their parents leave, and ſuffering martyrdom there, are excluded paradiſe for their diſobedience, yet eſcape hell becauſe they are martyrs.

ALARBES, a name given to thoſe Arabians who live in tents, and diſtinguiſh themſelves by their dreſs from the others who live in towns.

ALARES, in Roman antiquity, an epithet given to the cavalry, on account of their being placed in the two wings of the army.

ALARIS VENA, the innermoſt of the three veins in the bend of the arm.

ALARM, in the military art, denotes either the apprehenſion of being ſuddenly attacked; or the notice thereof, ſignified by firing a cannon, firelock, or the like. Falſe alarms are frequently made uſe of, to harraſs the enemy, by keeping them conſtantly under arms. Sometimes alſo this method is taken to try the vigilance of the picket-guard, and what might be expected from them in caſe of real danger.

ALARM-BELL, that rung upon any ſudden emergency, as a fire, mutiny, or the like.

ALARM-POST, or ALARM-PLACE, the ground for drawing up each regiment in caſe of an alarm. This is otherwiſe called *the rendezvous*.

ALARM, in fencing, is the ſame with what is otherwiſe called an appeal, or challenge.

ALASCANI, in church hiſtory, a ſect of Antilutherans, whoſe diſtinguiſhing tenet, beſides their denying baptiſm, is ſaid to have been this, that the words, *This is my body*, in the inſtitution of the euchariſt, are not to be underſtood of the bread, but of the whole action, or celebration of the ſupper. They are ſaid to have taken the name from one Joannes a Laſco, a Poliſh baron, ſuperintendant of the church of that country, in England.

ALASTROB, in alchymy, denotes lead.

ALATERNOIDES, in botany, ſignifies the caſſire.

ALATERNUS, in botany, the trivial name of a ſpecies of the ramanus.

ALAUDA, or LARK, in ornithology, a genus of birds of the order of paſſeres; there are 28 ſpecies of the alauda, of which the arvenſis, or common ſky-lark, is the moſt remarkable. This and the wood-lark are the only birds that ſing as they fly; this raiſing its note as it ſoars, and lowering it till it quite dies away as it deſcends. It will often ſoar to ſuch a height, that we are charmed with the muſic when we loſe ſight of the ſongſter; it alſo begins its ſong before the earlieſt dawn. Milton, in his Allegro, moſt beautifully expreſſes theſe circumſtances; and biſhop Newton obſerves, that the beautiful ſcene that Milton exhibits of rural cheerfulneſs, at the ſame time gives us a fine picture of the regularity of his life, and the innocency of his own mind: thus he deſcribes himſelf as in a ſituation

> To hear the lark begin his flight,
> And ſinging ſtartle the dull night,
> From his watch-tow'r in the ſkies,
> Till the dappled dawn doth riſe.

It continues its harmony ſeveral months, beginning early in the ſpring, on pairing. In the winter they aſſemble in vaſt flocks, grow very fat, and are taken in great numbers for our tables. They build their neſts on the ground, beneath ſome clod, forming it of hay, dry fibres, &c. and lay four or five eggs. The place theſe birds are taken in the greateſt quantities, is the neighbourhood of Dunſtable: the ſeaſon begins about the 14th of September, and ends the 25th of February; and during that ſpace, innumerable quantities are caught, which ſupply the markets of the metropolis.

ALAY, ſignifying in the Turkiſh language "The Triumph," a ceremony which accompanies the aſſembling together the forces of that vaſt empire upon the breaking out of a war. It conſiſts of the moſt inſipid buffoonery, and is attended with acts of the moſt ſhocking barbarity. That which took place upon occaſion of the late war between the Porte and Ruſſia is deſcribed by Baron Tott, in his Memoirs, as follows:

"It conſiſts in a kind of maſquerade, in which each trade ſucceſſively preſents to the ſpectators the mechanical exerciſe of its reſpective art. The labourer draws his plough, the weaver handles his ſhuttle, the joiner his plane; and theſe different characters, ſeated in cars richly ornamented, commence the proceſſion, and precede the ſtandard of Mahomet, when it is brought out of the ſeraglio to be carried to the army, in order to inſure victory to the Ottoman troops.

"This banner of the Turks, which they name *Sandjak-Cheriff*, or The Standard of the Prophet, is ſo revered among them, that, notwithſtanding its reputation has been ſo often tarniſhed, it ſtill retains their implicit confidence, and is the ſacred ſignal unto which they rally. Every thing proclaims its ſanctity. None but the emirs are allowed to touch it; they are its guards, and it is carried by their chief. The Muſſelmen alone are permitted to look upon it. If touched by other hands, it would be defiled; if ſeen by other eyes, profaned. In ſhort, it is encompaſſed by the moſt barbarous fanaticiſm.

"A long peace had unfortunately cauſed the ridiculouſneſs, and eſpecially the danger, of this ceremony to be forgotten. The Chriſtians imprudently crowded to ſee it; and the Turks, who, by the ſituation of their houſes, could make money of their windows, began to profit by the advantage; when an emir, who preceded the banner, proclaimed with a loud voice, 'Let no infidel dare to profane with his preſence the holy ſtandard of the prophet; and let every Muſſulman who perceives an unbeliever, make it known under pain of reprobation.'

"From that moment no aſylum was to be found; even thoſe became informers, who, by letting out their houſes, had rendered themſelves accomplices in the crime. A religious fury ſeized on every mind, and put arms in every hand; the more atrocious the cruelty, the more was it meretorious. No regard was paid to ſex or age; pregnant women, dragged by the hair, and trodden under feet by the multitude, periſhed in the moſt deplorable manner. Nothing was reſpected by theſe monſters; and under ſuch auſpices the Turks commenced the war."

ALB, or ALBE, in the Romiſh church, a veſtment of white linen hanging down to the feet, and anſwering to the ſurplice of the Engliſh clergy. In the ancient church, it was uſual, with thoſe newly baptized, to wear an Alb, or white veſtment; and hence the Sunday after Eaſter was called *dominica in albis*, on account of the Albs worn by thoſe baptized on Eaſter-day.

ALB is alſo a name of a Turkiſh coin, otherwiſe called *aſper*.

ALBADARA, ſignifies, in Arabic, the ſeſamoide bone of the firſt joint of the great toe, which is about the ſize of a ſmall pea; and is of the like uſe to that joint as the patella is to the knee.

ALBA FIRMA, or ALBUM, in our old cuſtoms, denoted rent paid in ſilver, and not in corn, which was called *black-mail*.

ALBA TERRA, one of the numerous names for the philoſopher's ſtone.

ALBAHURIM, *figura ſexdecim laterum*, a figure of great importance according to aſtrological phyſicians, who built their prognoſtics on it.

ALBANENSES, in church-hiſtory, the ſame with Albigenſes, according to ſome; according to others, different. Thoſe, however, who are for diſtinguiſhing them, attribute the ſame opinions to both; only making the Albanenſes to have been prior in reſpect of time, as having been found towards the cloſe of the eighth century; whereas the Albigenſes appeared not till the twelfth.

ALBANI, in Roman antiquity, a college of the *ſalii*, or prieſts of Mars; ſo called from mount Albanus, the place of their reſidence.

ALBANUM, in chemiſtry, implies ſalt of urine.

ALBARA, in medicine, ſignifies a malignant itch, originating from various cauſes.

ALBARAZIN, or ABAZARIN, a kind of Spaniſh wool.

ALBARDEOLA, in ornithology, a name given to the bird called the ſpoonbill.

ALBARII, in antiquity, properly denoted thoſe who gave the whitening to earthen veſſels, &c. In which ſenſe they ſtood contradiſtinguiſhed from *dealbatores*, who whitened walls.

ALBARIUM OPUS, in the ancient building, the incruſtation or covering of the roofs of houſes with white plaſter, made of mere lime. This is otherwiſe called *opus album*. It differs from *tectorium*, which is a common name given to all roofing or cieling, including even that formed of lime and ſand, or lime and marble; whereas *albarium* was reſtrained to that made of lime alone.

ALBATI EQUI, an appellation given to ſuch horſes, in the games of the ancient circus, as wore white furniture.

ALBATROSS, in ornithology, the name of a large ſea-bird common about the Cape of Good Hope. It is a thieviſh animal, and principally feeds on the prey which another ſea-bird, called the *booby*, provides for itſelf.

ALBE, a ſmall piece of money, current in Germany, worth only a French ſol and ſeven deniers.

ALBELEN, in ichthyology, a fiſh of the truttaceous kind, of a fine ſilver colour.

ALBELLUS, a ſpecies of the anſeres, belonging to the genus of Mergus.

ALBEOLA, a ſpecies of anas.

ALBERNUO, a kind of camblet, brought from the Levant by the way of Marſeilles.

ALBERTISTS, a ſect of ſcholaſtics, ſo named from their leader Albertus Magnus.

ALBERTUS, a gold coin, worth about 14 French livres: it was coined during the adminiſtration of Albertus archduke of Auſtria.

ALBESIA, in antiquity, a kind of ſhield, otherwiſe called *decumana*.

ALBICILLA, in phyſiology, implies a ſpecies of the eagle kind.

ALBIGENSES, in church hiſtory, a ſect or party of reformers, about Toulouſe and the Albigeois in Languedoc, who ſprung up in the twelfth century, and diſtinguiſhed themſelves by their oppoſition to the diſcipline and ceremonies of the Romiſh church.

This ſect had their name, it is ſuppoſed, either by reaſon there were great numbers of them in the dioceſe of Albi, or becauſe they were condemned by a council held in that city. In effect, it does not appear that they were known by this name before the holding of that council. The *Albigenſes* were alſo called *Albiani*, *Albigeſei*, *Albii*, and *Albanenſes*, though ſome diſtinguiſh theſe laſt from them. Other names given to them are, *Henricians*, *Abelardiſts*, *Bulgarians*, &c. ſome on account of the qualities they aſſumed; others on that of the country from whence it is pretended they were derived; and others on account of perſons of note who adopted their cauſe, as Peter de Brius, Arnold de Breſſe, Abelard, Henry, &c. Berengarius, if not Wickliff himſelf, is by ſome ranked in the number. The *Albigenſes* are frequently confounded with the *Waldenſes*; from whom, however, they differ in many reſpects, both as being prior to them in point of time, as having their origin in a different country, and as being charged with divers hereſies, particularly Manicheiſm, from which the *Waldenſes* are exempt. But ſeveral proteſtant writers have vindicated them from that imputation. Dr. Allix ſhows, that a great number of *Manichees* did ſpread over the weſtern countries from Bulgaria; and ſettled in Italy, Languedoc, and other places, where there were alſo *Albigenſes*; by which means, being both under the imputation of *hereſy*, they came, either by ignorance or malice, to be confounded, and called by the ſame common name, though in reality entirely different.

ALBIGENSES is alſo a name ſometimes given to the followers of Peter Vaud, or Waldo; and hence ſynonymous with what we more properly call *Waldenſes*, or Poor Men of Lyons. In this ſenſe the word is applied by Camerarius, Thuanus, and ſeveral other writers.

ALBINI, in antiquity, the workmen employed in what was called *Opus Albarium*. They make a different profeſſion from the *dealbatores* or *whiteners*.

ALBINOS, the name by which the Portugueſe call the white Moors, who are looked upon by the negroes as monſters. They at a diſtance might be taken for Europeans; but, when you come near them, their white colour appears like that of perſons affected with a leproſy.

In Sauſſure's *Voyages dans les Alpes*, is the following account of two boys, at Chamouni, who have been called *Albinos*. "The elder, who was at the end of the year 1785 about twenty, or one-and-twenty years of age, had a dull look, with lips ſomewhat thick, but nothing elſe in his features to diſtinguiſh him from other people. The other, who is two years younger, is rather a more agreeable figure: he is gay and ſprightly, and ſeems not to want wit. But their eyes are not blue; the iris is of a very diſtinct roſe-colour; the pupil too, when viewed in the light, ſeems decidedly red; which ſeems to demonſtrate, that the interior membranes are deprived of the uvea, and of that black mucous matter that ſhould line them. Their hair, their eye-brows, and eye-laſhes, the down upon their ſkin, were all, in their infancy, of the moſt perfect milk-white colour, and very fine; but their hair is now of a reddiſh caſt, and has grown pretty ſtrong. Their ſight too is ſomewhat ſtrengthened; though they exaggerate to ſtrangers their averſion for the light, and half-ſhut the eye-lids, to give themſelves a more extraordinary appearance. But thoſe who, like me, have ſeen them in their infancy, before they were tutored to this deceit, and when too few people came to Chamouni to make this affectation profitable to them, can atteſt that then they were not very much offended with the light of day. At that time, they were ſo little deſirous of exciting the curioſity of ſtrangers, that they hid themſelves to avoid ſuch; and it was neceſſary to do a ſort of violence to them before they could be prevailed on to allow themſelves to be inſpected. It is alſo well known at Chamouni, that when they were of a proper age they were unable to tend the cattle like the other children at the ſame age; and that one of their uncles maintained them out of charity, at a time of life when others were capable of gaining a ſubſiſtence by their labour.

"I am therefore of opinion, that we may conſider theſe two lads as true albinos: for if they have not the thick lips and flat noſes of the white negroes, it is becauſe they are albinos of Europe, not of Africa. This infirmity affects the eyes, the complexion, and the colour of the hair; it even diminiſhes the ſtrength, but does not alter the conformation of the features. Beſides, there are certainly in this malady various degrees: ſome may have leſs ſtrength, and be leſs able to endure the light: but theſe circumſtances in thoſe of Chamouni are marked with characters ſufficiently ſtrong to intitle them to the unhappy advantage of being claſſed with that variety of the human ſpecies denominated albinos.

"When nature preſents the ſame appearance often, and with circumſtances varied, we may at laſt diſcover ſome general law, or ſome relation which that appearance has with known cauſes: but when a fact is ſo ſingular and ſo rare, as that of thoſe albinos, it gives but little ſcope to conjectures; and it is very difficult to verify thoſe by which we attempt to explain it.

"I at firſt imagined that this diſeaſe might be referred to a particular ſort of organic debility; that a relaxation of the lymphatic veſſels within the eye might ſuffer the globules of the blood to enter too abundantly into the iris, the uvea, and even into the retina, which might occaſion the redneſs of the iris and of the pupil. The ſame debility ſeemed alſo to account for the intolerance of the light, and for the whiteneſs of the hair.

"But a learned phyſiologiſt, M. Blumenbach, profeſſor in the univerſity at Gottingen, who has made many profound obſervations on the organs of ſight, and has conſidered with great attention the albinos of Chamouni, attributes their infirmity to a different cauſe.

"The ſtudy of comparative anatomy has furniſhed him with frequent opportunities of obſerving this phenomenon; he has found it in brutes, in white dogs, and in owls; he ſays, it is generally to be ſeen in the warm-blooded animals; but that he has never met with it in thoſe with cold blood.

"From his obſervations, he is of opinion, that the redneſs of the iris, and of the other internal parts of the eye, as well as the extreme ſenſibility that accompanies this redneſs, is owing to the total privation of that brown or blackiſh mucus, that, about the fifth week after conception, covers all the interior parts of the eye in its ſound ſtate. He obſerves, that Simon Pontius, in his treatiſe *de Coloribus Oculorum*, long ago remarked, that in blue eyes the interior membranes were leſs abundantly provided with this black mucus, and were therefore more ſenſible to the action of light. This ſenſibility of blue eyes agrees very well, ſays M. Blumenbach, with northern people, during their long twilight; while, on the contrary, the deep black in the eyes of negroes enables them to ſupport the ſplendor of the ſun's beam in the torrid zone.

"As to the connection between this red colour of the eyes and the whiteneſs of the ſkin and hair, the ſame learned phyſiologiſt ſays, that it is owing to a ſimilarity of ſtructure, *conſenſus ex ſimilitudine fabricæ*. He aſſerts, that this black mucus formed only in the delicate cellular ſubſtance, which has numerous blood-veſſels contiguous to it, but contains no fat; like the inſide of the eye, the ſkin of negroes, the ſpotted palate of ſeveral domeſtic animals, &c. And, laſtly, he ſays, that the colour of the hair generally correſponds with that of the iris. *Gazette litt. de Gotingue*, Oct. 1784.

"At the very time that M. Blumenbach was reading this memoir to the Royal Society of Gottingen, M. Buzzi, ſurgeon to the hoſpital at Milan, an eleve of the celebrated anatomiſt *Moſcati*, publiſhed in the *Opuſcoli Scelti de Milan*, 1784, t. vii. p. 11. a very intereſting memoir, in which demonſtrates by diſſection what Blumenbach had only ſuppoſed.

"A peaſant of about 30 years of age died at the hoſpital of Milan of a pulmonary diſorder. His body, being expoſed to view, was exceedingly remarkable by the uncommon whiteneſs of the ſkin, of the hair, of the beard, and of all the other covered parts of the body. M. Buzzi, who had long deſired an opportunity of diſſecting ſuch a ſubject, immediately ſeized upon this. He found the iris of the eyes perfectly white, and the pupil of a roſe-colour. The eyes were diſſected with the greateſt poſſible care, and were found entirely deſtitute of that black membrane which anatomiſts call the *uvea*; it was not to be ſeen either behind the iris, or under the retina: within the eye there was only found the choroid coat extremely thin and tinged, of a pale red colour, by veſſels filled with diſcoloured blood. What was more extraordinary, the ſkin, when detached from different parts of the body, ſeemed alſo entirely diveſted of the *rete mucoſum*: maceration did not diſcover the leaſt veſtige of this, not even in the wrinkles of the abdomen, where it is moſt abundant and moſt viſible.

"M. Buzzi likewiſe accounts for the whiteneſs of the ſkin and of the hair, from the abſence of the *rete mucoſum*, which, according to him, gives the colour to the cuticle, and to the hairs that are ſcattered over it. Among other proofs of this opinion, he alleges a well known fact, that if the ſkin of the blackeſt horſe be accidentally deſtroyed in any part of the body, the hairs that afterwards grow on that part are always white, becauſe the *rete mucoſum* which tinges thoſe hairs is never regenerated with the ſkin.

"The proximate cauſe of the whiteneſs of albinos, and the colour of their eyes, ſeems therefore pretty evidently to depend on the abſence of the *rete mucoſum:* But what is the remote cauſe?

"In the firſt place, it ſeems probable that men affected with this infirmity form no diſtinct ſpecies, for they are produced from parents that have dark ſkins and black eyes. What is then that deſtroys the *rete mucoſum* in ſuch perſons? M. Buzzi relates a ſingular fact, which ſeems to throw ſome light on this ſubject.

"A woman of Milan, named Calcagni, had ſeven ſons. The two eldeſt had brown hair and black eyes; the three next had white ſkins, white hair, and red eyes: the two laſt reſembled the two eldeſt. It was ſaid that this woman, during the three pregnancies that produced the albinos, had a continual and immoderate appetite for milk, which ſhe took in great quantities: but that when ſhe was with child of the other four children, ſhe had no ſuch deſire. It is not however aſcertained, that this preternatural appetite was not itſelf the effect of a certain heat, or internal diſeaſe, which deſtroyed the *rete mucoſum* in the children before they were born.

"The albinos of Chamouni are alſo the offſpring of parents with dark ſkins and black eyes. They have three ſiſters by the ſame father and mother, who are alſo brunettes. One of them that I ſaw had the eyes of a dark brown, and the hair almoſt black. They are ſaid, however, to be all afflicted with a weakneſs of ſight. When the lads are married, it will be curious to obſerve how the eyes of their children will be formed. The experiment would be particularly deciſive if they were married to women like themſelves. But this faulty conformation ſeems to be more rare among women than among men; for the four of Milan, the two of Chamouni, the one deſcribed by Mauperitus, the one by Helvetius, and almoſt all the inſtances of theſe ſingular productions, have been of our ſex. It is known, however, that there are races of men and women affected with this diſeaſe, and that theſe races perpetuate themſelves, in Guinea, in Java, at Panama, &c.

"Upon the whole, this degeneration does not ſeem to be owing to the air of the mountains; for though I have traverſed the greateſt part of the Alps, and the other mountains of Europe, theſe are the only individuals of the kind ever I met with."

ALBION, the ancient name of Britain.

ALBIREO, in aſtronomy, a ſtar of the third or fourth magnitude, in the conſtellation Cygnus.

ALBOGALERUS, in Roman antiquity, a white cap worn by the *flamen dialis*, on the top of which was an ornament of olive branches.

ALBORAK, in the Mahometan theology, the beaſt on which the pretended prophet is ſaid to have rode in his extraordinary aërial journies. It is repreſented as of an intermediate ſhape and ſize, between an aſs and a mule; and many fabulous accounts are given of it by the Arabian commentators.

ALBORO, in ichthyology, a name by which the erythrinus, a ſmall red fiſh, caught in the Mediterranean, is commonly known in the markets of Rome and Venice.

ALBUCA, Baſtard star-of-Bethlehem: A genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 10th order, *Coronariæ.* For its characters, ſee Syſtem of Botany. Of this genus Linnæus reckons only two ſpecies. The major, or ſtar-flower, with ſpear-ſhaped leaves, a native of Canada, and North America: and the minor, or African ſtar-flower, a native of the Cape of Good Hope.

The Canada albuca is hardy; ſo the roots may be planted about four inches deep in a border of light earth, where they will thrive and produce their flowers late in the ſummer: but as the ſeeds do not often ripen in Britain, and the bulbs put out few off-ſets, the plants are not common in this country. The African ſort generally flowers twice a-year; firſt in March or April, and again in July or Auguſt; and if its roots are kept in pots filled with light earth, ſheltered under a hot-bed frame, they will flower even in winter.

ALBUGINEA Tunica, in anatomy, the third or innermoſt coat or covering of the teſtes; it is likewiſe the name given to one of the coats of the eye.

ALBUGINEUS, in anatomy, a term ſometimes applied to the aqueous humour of the eye.

ALBUGO, or Leucoma, in medicine, a diſtemper occaſioned by a white opaque ſpot growing on the cornea of the eye, and obſtructing viſion.

ALBULA, in ichthyology, a ſpecies of the truttaceous kind of fiſhes having no teeth: there are various kinds under this denomination.

ALBUM, in antiquity, a kind of white table, or regiſter, wherein the names of certain magiſtrates, public tranſactions, &c. were entered. Of theſe there were various ſorts; as the *album decurionum, album ſenatorum, album judicum, album prætoris*, &c.

Album *Decurionum*, was the regiſter wherein the names of the *decuriones* were entered. This is otherwiſe called *matriculatio decurionum.*

Album *Senatorum*, the liſt of ſenators names, which was firſt introduced by Auguſtus, and renewed yearly.

Album *Judicum*, that wherein the names of the perſons of thoſe decuriæ who judged at certain times, were entered.

Album *Prætoris*, that wherein the *formulæ* of all actions, and the names of ſuch judges as the prætor had choſen to decide cauſes, were written.

The high-prieſt entered the chief tranſactions of each year into an *album*, or table, which was hung up in his houſe for the public uſe.

Album is alſo uſed, in later times, to denote a kind of table, or pocket-book, wherein the men of letters with whom a perſon has converſed, inſcribe their names with ſome ſentence or motto. The famous Algernon Sydney being in Denmark, was by the univerſity of Copenhagen preſented with their *album*, whereupon he wrote theſe words:

——— *Manus hæc inimica tyrannis*
Enſe petit placidam ſub libertate quietem.

Album *Græcum*, among phyſicians, the white dung of dogs, formerly preſcribed for inflammations of the throat, &c. but now juſtly deſpiſed.

ALBUMEN, the white of an egg. This, according to Boerhaave, makes an extraordinary menſtruum. Being boiled hard in the ſhell, and afterwards ſuſpended in the air by a thread, it reſolves and drops down into an inſipid, ſcentleſs liquor, which appears to be that anomalous unaccountable menſtruum ſo much uſed by Paracelſus; and will, though it contains nothing ſharp, oleaginous, or ſaponaceous, make a thorough ſolution of myrrh; which is more than either water, oil, ſpirits, or even fire itſelf, can effect.

A little putrid white of egg taken into the ſtomach, occaſions a nauſea, horror, fainting, vomiting, diarrhœa, and gripes; it inflames the bile, excites heat, thirſt, fever; and diſſolves the humours like the plague. On the contrary, the white of freſh-laid eggs, if taken while warm from the hen, is extremely nouriſhing to the infirm: it may be taken in luke-warm milk; but if any other heat is applied to it, the nutritious quality will be deſtroyed. The freſh white of egg prevents burns from riſing in bliſters, if it is uſed immediately after the accident: it mitigates inflammations of the eyes, and preſerves the face from ſun-burning. In pharmacy, it is uſed as a medium to render balſams and turpentines, &c. miſcible with aqueous fluids; but as it diſagrees with many ſtomachs when thus taken, a mucilage of gum arabic may ſupply its place, it being as good a medium in ſimilar circumſtances, and not apt to offend the tendereſt ſtomach. White of eggs are alſo uſeful for clarifying liquors; to which purpoſe, being mixed and incorporated with the liquors to be clarified, and the whole afterwards boiled, the whites of eggs are by this means brought together and hardened, and thus carry off the groſs parts of the liquor along with them.

ALBURN, the Engliſh name of a compound colour, being a mixture of white and red, or reddiſh brown.

ALBURNUM, the ſoft white ſubſtance which in trees is found between the liber or inner bark and the wood, and in progreſs of time acquiring ſolidity, becomes itſelf the wood. From its colour and comparative ſoftneſs, it has been ſtyled by ſome writers the fat of trees, *adeps arborum.*

The alburnum is found in largeſt quantities in trees that are vigorous; though in ſuch as languiſh, or are ſickly, there is a great number of beds. In an oak ſix inches in diameter, this ſubſtance is nearly equal in bulk to the wood. In a trunk of one foot diameter, it is as one to three and a half; of two and a half feet diameter, as one to four and a half, &c. but theſe proportions vary according to the health and conſtitution of the trees. The alburnum is frequently gnawed in pieces by inſects, which lodge in the ſubſtance, and are nouriſhed from it.

ALBURNUS, in ichthyology, a ſpecies of the cyprinus of Linnæus.

ALBUS Piscis, in ichthyology, a white fiſh, commonly called the jentling.

ALCA, or Auk, in ornithology, a genus of the order of anſeres. The beak of this genus is without teeth, ſhort, convex, compreſſed, and frequently furrowed tranſverſely; the inferior mandible is gibbous near the baſe; the feet have generally three toes. The ſpecies of the Alca are 12; of which the moſt remarkable are,

The impennis, northern penguin, or great auk, with a compreſſed bill furrowed on each ſide, and an oval ſpot on each ſide of the eyes. According to Mr. Martin, this bird breeds on the iſle of St. Kilda; appearing there the beginning of May, and retiring the middle of June. It lays one egg, which is ſix inches long, of a white colour; ſome are irregularly marked with purpliſh lines croſſing each other, others blotched with black, and ferruginous about the thicker end: if the egg is taken away, it will not lay another that ſeaſon.

ALCAICS, in ancient poetry, a denomination given to ſeveral kinds of verſe, from Alcæs, their inventor.

The firſt kind conſiſts of five feet, viz. a ſpondee, or iambic; an iambic; a long ſyllable; a dactyle; another dactyle: ſuch as the following verſe of Horace,

Omneſs | *eo* | *dem cogimur,* | *omnium*
Verſe | *tur ur* | *nâ* | *ſerins* | *ocyus* |
Sors exitura.

The ſecond kind conſiſts of two dactyles and two trochees: as,

Exili | *um impoſi* | *tura* | *cymbæ.*

Beſides theſe two, which are called *dactylic Alcaïcs*, there is another ſtyled ſimply *Alcaïc*; conſiſting of an epitrite; a choriambus; another choriambus; and a bacchius: the following is of this ſpecies,

Cur timet fla | *vum Tiberim tan* | *gere, cur* | *olivum?*

Alcaic *Ode*, a kind of manly ode compoſed of ſeveral ſtrophes, each conſiſting of four verſes; the two firſt of which are always Alcaïcs of the firſt kind; the third verſe is a diameter hypercatalecti, or conſiſting of four feet and a long ſyllable; and the fourth verſe in an Alcaïc of the ſecond kind. The following ſtrophe is of this ſpecies, which Horace calls *minaces Alcæi camenæ.*

Non poſſidentem multa vocaveris
Recte beatum: rectius occupat
Nomen beati, qui deorum
Muneribus ſapienter uti, &c.

ALCAID, Alcayde, or Alcalde, in the polity of the Moors, Spaniards, and Portugueſe, a magiſtrate or officer of juſtice, anſwering nearly to the French provoſt and the Britiſh juſtice of peace. The alcaid among the Moors is veſted with ſupreme juriſdiction, both in civil and criminal caſes.

ALCALA ed Guadeira, a ſmall town of Spain, in Andaluſia, upon the river Guadeira. Here are abundance of ſprings, from whence they convey water to Seville by an aqueduct.

ALCALY, ſynonymous with Alcali, or Alkali.

ALCANNA, in commerce, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a conſiderable trade. It is much uſed by the Turkiſh women to give a golden colour to their nails and hair. In dyeing, it gives a yellow colour when ſteeped with common water, and a red one when infuſed in vinegar. There is alſo an oil extracted from the berries of alcanna, and uſed in medicine as a calmer.

Knights of ALCANTARA, a military order of Spain. They make a very conſiderable figure in the hiſtory of the expeditions againſt the Moors. The knights of Alcantara make the ſame vows as thoſe of Calatrava, and are only diſtinguiſhed from them by this, that the croſs fleur de lys, which they bear over a large white cloak, is of a green colour. They poſſeſs 37 commanderies. By the terms of the ſurrender of Alcantara to this order, it was ſtipulated, that there ſhould be a confraternity between the two orders, with the ſame practices and obſervances in both; and that the order of Alcantara ſhould be ſubject to be viſited by the grand maſter of Calatrava. But the former ſoon releaſed themſelves from this engagement, on pretence that their grand maſter had not been called to the election of that of Calatrava, as had been likewiſe ſtipulated in the articles. After the expulſion of the Moors, and the taking of Granada, the ſovereignty of the order of Alcantara and that of Calatrava was ſettled in the crown of Caſtile by Ferdinand and Iſabella. In 1540, the knights of Alcantara ſued for leave to marry, which was granted them.

ALCAVALA, in the Spaniſh finances, was at firſt a tax of ten per cent. afterwards of fourteen per cent. and is at preſent of only ſix per cent. upon the ſale of every ſort of property, whether moveable or immoveable; and it is repeated every time the property is ſold. The levying of this tax requires a multitude of revenue officers ſufficient to guard the tranſportation of goods, not only from one province to another, but from one ſhop to another. It ſubjects not only the dealers in ſome ſorts of goods, but thoſe in all ſorts, every farmer, every manufacturer, every merchant and ſhopkeeper, to the continual viſits and examination of the tax-gatherers. Through the greater part of a country in which a tax of this kind is eſtabliſhed, nothing can be produced for diſtant ſale. The produce of every part of the country muſt be proportioned to the conſumption of the neighbourhood. It is to the alcavala, accordingly, that Uſtaritz imputes the ruin of the manufactures of Spain. He might have imputed to it likewiſe the declenſion of agriculture, it being impoſed not only upon manufactures, but upon the rude produce of the land.

ALCE, Alces, or Elk, in zoology, the trivial name of a ſpecies of the cervus, belonging to the order of mammalia pecora.

ALCEA, the Holly-hock: a genus of the polyandria order, belonging to the monodelphia claſs of plants; and in the natural method ranking under the 37th order, Columniferæ. For its characters, ſee Syſtem of Botany. The *ſeeds* are ſolitary, reniform, and depreſſed.

Linnæus mentions two diſtinct ſpecies of this genus, viz. the *roſea* and *ficifolia.*

ALCEDO, or Kingsfisher, in ornithology, a genus of the order of picæ. The alcedo has a long, ſtrait, thick, triangular bill; with a fleſhy, plain, ſhort, flat tongue.

Of this genus there are a great many ſpecies, with one or other of which almoſt every part of the world is furniſhed. Moſt of them frequent rivers, and live on fiſh, the ſingularity of catching which is admirable: ſometimes they hover over the water, where a ſhoal of ſmall fiſhes is ſeen playing near the ſurface; at other times they wait with attention, on ſome low branch hanging over the water, for the approach of a ſingle one who is ſo unlucky as to ſwim that way; in either caſe dropping like a ſtone, or rather darting with rapidity on his prey; when, ſeizing it croſſways in his bill, it retires to a reſting place to feaſt on it; which it does piecemeal, bones and all, without reſerve, afterwards bringing up the indigeſtible parts in pellets, like birds of prey. The wings of moſt of this genus are very ſhort; yet the birds fly rapidly, and with great ſtrength. It may be remarked, that throughout this genus, blue, in different ſhades, is the moſt predominant colour. The ſpecies found in the South Sea Iſlands are held in a kind of ſuperſtitious veneration by the natives of the places they ſeverally inhabit, perhaps on account of their being frequently ſeen flying about the morals or burial-places. That which inhabits Otaheite, where it is called *Eroro*, is accounted particularly ſacred, and not allowed to be taken or killed. The moſt diſtinguiſhed among the various ſpecies of this bird are the following:

1. The iſpida, or common kingsfiſher, is not much larger than a ſwallow; its ſhape is clumſy; the bill diſproportionably long; it is two inches from the baſe to the tip; the upper chap black, and the lower yellow. But the colours of this bird atone for its inelegant form: the crown of the head and the coverts of the wings are of a deep blackiſh green, ſpoted with bright azure: the back and tail are of the moſt reſplendent azure; the whole under-ſide of the body is orange-coloured; a broad mark of the ſame paſſes from the bill beyond the eyes; beyond that is a large white ſpot: the tail is ſhort, and conſiſts of twelve feathers of a rich deep blue; the feet are of a reddiſh yellow, and the three joints of the outmoſt toe adhere to the middle toe, while the inner toe adheres only by one.

This ſpecies is the αλκυωναφωνος, or mute halcyon of Ariſtotle, which he deſcribes with more preciſion than is uſual with that great philoſopher. He relates, that it reſembled thoſe concretions that are formed by the ſea-water; that it reſembled the long-necked gourd; that it was hollow within; that the entrance was very narrow, ſo that, ſhould it overſet, the water could not enter; that it reſiſted any violence from iron, but could be broke with a blow from the hand; and that it was compoſed of the bones of the Βελονη, or ſea-needle. The neſt had medical virtues aſcribed to it; and from the bird was called *Halcyoneum*. In a fabulous age, every odd ſubſtance that was flung aſhore received that name; a ſpecies of tubular coral, a ſponge, a zoophite, and a miſcellaneous concrete, having by the ancients been dignified with that title from their imaginary origin. Yet much of this ſeems to be founded on truth. The form of the neſt is juſtly deſcribed; and the materials which Ariſtotle ſays it was compoſed of, are not entirely of his own invention. Whoever has ſeen the neſt of the kingsfiſher, will obſerve it ſtrewed with the bones and ſcales of fiſh; the fragments of the food of the owner and its young.

Ariſtotle and Pliny tell us, that this bird was moſt common in the ſeas of Sicily; that it ſat only a few days, and thoſe in the depth of winter; and during that period the mariner might ſail in full ſecurity; for which reaſon they were ſtyled *Halcyon days.*

In after-times, theſe words expreſſed any ſeaſon of proſperity: theſe were the *Halcyon days* of the poets; the brief tranquillity, the *ſeptem placidi dies*, of human life.

This bird is found not only in Britain, but throughout Europe, Aſia, and Africa.

2. The rudis, or Egyptian kingsfiſher, as deſcribed by Haſſelquiſt, is the ſize of the Royſton crow.

3. Le taparara of Buffon is about the ſize of a ſtarling.

4. The torquata, or cinereous kingsfiſher, is about the ſize of a magpie.

The jacamars are much allied to this genus, and have been ranked under it by Linnæus: their toes are, however, differently placed; their food alſo is different, being inſects alone, and not fiſh; and their haunts are different, being moiſt woods, and not ſhores or the banks of rivers.

5. The galbula, or green jamacar, is about the ſize of a lark. The bill is black, of a ſquare form, a little incurvated and ſharp at the point: the plumage in general, in the upper part of the body, is of a moſt brilliant green, gloſſed with copper and gold in different lights: the belly, throat, and vent, are rufous: the tail is compoſed of ten feathers, and ſhaped like a wedge: the legs are of a greeniſh yellow, very ſhort and weak; the claws are black. This ſpecies is found both in Guiana and Braſil, in the moiſt woods, which it prefers to the more dry ſpots, for the ſake of inſects, on which it feeds.

6. The paradiſea, or paradiſe jacamar, is of the ſame ſize with the former, and has a ſimilar bill: the throat, fore part of the neck, and under wing coverts, are white: the reſt of the plumage is of a deep dull green, in ſome lights appearing almoſt black, in others with a ſlight gloſs of violet and copper bronze; the tail is compoſed of twelve feathers of unequal

lengths: the two middle ones longeſt: the legs are black: the toes are placed two before and two behind, and pretty much united. It inhabits Surinam; and like the others, it feeds on inſects; and ſometimes, contrary to them, frequents open places. It flies farther at a time and perches on the tops of trees; it is frequently found with a companion, not being quite ſo ſolitary a bird as the other. It alſo differs in the note, having a kind of ſoft whiſtle often repeated, but not heard a great way off.

ALCHATA, in ornithology, implies a ſpecies of the tetrao.

ALCHEMILLA, or **Ladies-mantle**, a genus of the monogynia order, belonging to the tetrandia claſs of plants; and in the natural method ranking under the 35th order *Senticoſæ*. For its characters, ſee Syſtem of **Botany**. Of this genus there are three ſpecies.

1. The vulgaris, or common ladies-mantle, with leaves plaited like a fan, and yellowiſh-green bloſſoms. It grows naturally in paſture-lands in this as well as in moſt other countries in Europe. The leaves diſcover to the taſte a moderate aſtringency; and were formerly much eſteemed in ſome female weakneſſes, and in fluxes of the belly. 2. The alpina, or cinque-foil ladies-mantle, with finger-ſhaped ſawed leaves, and greeniſh bloſſoms. It is a native of the mountainous parts of Europe. 3. The minor, or at leaſt ladies-mantle, with five ſmooth leaves growing at a joint and cut into many ſegments. It grows naturally in Sweden, Lapland, and other cold countries.

Theſe plants have perennial roots, and annual ſtalks. They are eaſily propagated by parting of their roots, or ſowing their ſeeds in autumn.

ALCHEMIST, a practitioner in alchemy.

ALCHEMY, or **Alchymy**, which the ancients called Halchymia, denotes the moſt ſecret parts of chemiſtry. It may be divided into three parts, namely, 1. the making of gold; 2. the diſcovery of an univerſal medicine, or panacea; and, 3. the diſcovery of an univerſal diſſolvent, or alkaheſt.

How far theſe may be accounted proper objects of ſtudy, the diſappointments, which all the practitioners in this art have met with, will readily certify. For after a ſucceſſion of labour and expence for many ages, and in different regions, not one of the pretenders to this art has been able to make gold, or to produce any one medicine, diſſolvent or ferment, capable of operating effectually on every body or ſubject. Yet we find the names of very learned men in the liſt of authors, who have eſpouſed the ſtudy of Alchemy; and ſome of them vain enough to imagine the poſſibility of diſcovering an univerſal menſtruum to which ſome have given the name of the Philoſopher's Stone, for performing the ſecret myſteries of this art: therefore this menſtruum is the greateſt object of the Alchemiſt, becauſe without it there can be no tranſmutation.

According to the received opinion of adepts in this pretended ſcience, nothing more is required than caſting a ſmall quantity of the menſtruum upon metals in infuſion, which will convert all the true mercurial part of metal into pure gold; there being no other requiſite for this wonder-working change, than to do that by art, which nature does in many years and ages; for as gold and lead do but little differ in weight, there cannot be much in lead beſides mercury and gold: conſequently, if any body could be found that would agitate all the parts of lead, ſo as to burn all that is not mercury therein, having alſo ſulphur to fix the mercury; the queſtion then is, Would not the maſs remaining be converted into pure gold?

Such is the foundation for the opinion of the Philoſopher's Stone, which the Alchemiſts contend to be a moſt fixed concentrated fire, which, as ſoon as it melts with any metal, does, by a magnetic virtue, immediately unite itſelf to the mercurial body of the metal, volatilizes and cleanſes off all that is impure therein, and leaves nothing but a maſs of pure gold.

Upon this principle many have ſet out to try their fortunes in the Alchemiſt's furnace. Some have attempted the tranſmutation of the moſt imperfect into perfect metals, both ſilver and gold, by ſeparation; others by maturation and real tranſmutation.

Thoſe who proceed by the method of ſeparation muſt ſuppoſe that all inferior metals contain a quantity of gold more or leſs. For unleſs it could be made appear that ſuch a ſeparation was ever diſcovered, and that the quantity of gold ſeparated from the baſer metals was ſufficient to defray the expence of the operation, neither of which can be affirmed, there can be little or no hopes of making gold by this method.

The proceſs by maturation is no leſs liable to exceptions. Nothing but mercury could be changed into gold by maturation, becauſe the principles of all other metals not being pure mercury, their abundant heterogeneous particles, and the ſmall quantity of imperfect ones which enter into their compoſition, cannot be ſeparated from it by a digeſtion.

Here Mr. Chambers interferes with a ſuppoſition, that could mercury be once purged of its impurities by maturation, it might eaſily be changed into gold, becauſe (ſays he) it would then be as heavy as gold. A very ſuperficial reaſon! for weight is not the eſſential quality conſtitutive of that perfect metal. It muſt be ductile and malleable; qualities which have never been diſcovered by the maturation of mercury. Beſides, there is another moſt eſſential quality: the mercury ſhould equal gold in its fixedneſs in the fire, reſulting from the homogenity and equality of its parts, which all have equal pores or interſtices through which the fiery corpuſcules find an eaſy paſſage; and therefore cannot haſten its fuſion with the ſame facility as that of leſs perfect metals, where, through the obliquity and unequal poſition of the pores, they meet with more reſiſtance.

The affair of Monſ. Langueille, an adapt in this art about the middle of the laſt century, will ſerve to illuſtrate and confirm this obſervation. This gentleman piqued himſelf very highly on having diſcovered the art of converting mercury into gold by maturation; but when his metal ſo prepared was put into the crucible, he was ſoon convinced of his error and preſumption: for its pores not being in the ſame poſition, nor at the ſame equal diſtances, his metal evaporated into ſmoak.

The Alchemiſts in general ſeem to have the practice of real tranſmutation moſt at heart; and they ſay this tranſmutation of metals is to be done by melting them in the fire, and by caſting a certain quantity of a powder, termed by them the *powder of projection*, into the matter fuſed, whoſe effects they aſſert will be the ſame as mentioned before reſpecting the Philoſopher's Stone; the practability of which operation has never been proved by any ſcientific profeſſor more fully than by the late Dr. Price, as the following extracts from the London Review for October 1782 evince.

" Account of ſome experiments on mercury, ſilver and gold,
" made at Guildford in May 1782, in the laboratory of
" James Price, M. D. F. R. S.

" We ſhall proceed to the experiments, ſeven in number, three of which were made in the preſence of many great and reſpectable perſons, to whom the author appeals for the truth of his accounts; and the reſult of all theſe experiments was, the partial tranſmutation of Mercury into Gold or Silver, and of Silver into Gold.

" The author informs us, that the perſons preſent at the firſt of theſe experiments were, the Rev. Mr. Anderſon, a clergyman reſiding near Guildford, well verſed in experimental philoſophy, and ſtudious of its chemical branches; Capt. Francis Groſe, a gentleman advantageouſly known in the chemical world by his reſearches and publications; Mr. Ruſſel, a magiſtrate of the place, and a perſon, from his technical employments, converſant with the appearance of the precious metals, well acquainted with the uſual operations on them, and with the methods employed by artiſts for aſcertaining their commercial value; and enſign D. Groſe. And theſe gentlemen ſeem, at the expreſs inſtance of the author, to have provided every inſtrument or ingredient employed in the proceſs, except the **powder itself**, which poſſeſſed ſuch wonderful properties.

" Half an ounce of mercury, the principal ingredient, was bought by Capt. Groſe at an apothecary's in the town, and placed in a crucible brought by Mr. Ruſſel, on a flux, the ingredients of which were either brought or examined by the company, and the very mortar in which they were pounded previouſly inſpected. Before the crucible was placed on the fire, half a grain of a deep red powder, furniſhed by the author, was weighed by Mr. Ruſſel, and added by Mr. Anderſon to the other ingredients.

" In about a quarter of an hour after the projection of this powder, and placing the crucible on the fire, it was obſerved, 'that though the crucible was now become red-hot, the mercury ſhewed no ſigns of evaporation, or even of boiling.' And the fire being raiſed to a ſtrong glowing red, or white-red heat, a clean iron rod was dipped into the matter, and the ſcoriæ which adhered to the point being knocked off when cold, were found to be replete with ſmall globules of whitiſh metal, which the author repreſented as 'an intermediate ſubſtance, between mercury and a more perfect metal.'

" A ſmall quantity of borax, brought by Mr. Ruſſel, was now injected into the crucible; and the matter kept in a ſtrong red-white heat about a quarter of an hour; when the crucible being cooled, and broke, a globule of yellow metal was found at the bottom; which, together with ſome ſmaller globules found in the ſcoriæ, weighed full ten grains. This metal was ſealed up in a phial; and the next morning, in the preſence of the ſame company, and Captain Auſten, the large globule was hydroſtatically examined, when its ſpecific gravity, compared with water, was eſtimated to be nearly in the ratio of 20 to 1. The globule, which weighed nine grains and a quarter, was then beat into a thin plate, and examined, in the manner of artiſts, by Mr. Ruſſel, who declared it to be as good gold as the grain gold of the refiners; and half the plate being ſent to Dr. Higgins, he was alſo of opinion that it was pure gold.

" The author mentions other chemical trials which were alſo made, and eſtabliſhed its pretence to the character of gold.

" In the ſecond and third experiments, a white powder is projected on mercury, which produces a white metal: the mercury lying quiet after the crucible had acquired a red heat in the former of theſe experiments; but in the latter, it accidentally began to boil; when on applying the white powder, the ebullition ceaſed, and did not return.

“ In the fourth and fifth of theſe experiments, ſilver appeared to be tranſmuted by the projection of a ſmall quantity of the red powder ; and to be found, on a regular aſſay, to contain pure gold, to the quantity of one-eighth of the joint weight.

“ In the ſixth experiment, made before Sir Philip Norton Clarke, the Rev. Mr. Anderſon, Captain Groſe, Dr. Spence, Enſign Groſe, and Mr. Hallamby, two ounces of quickſilver were rubbed with a drop or two of vitriolic æther, in a ſmall mortar of Wedgwood's ware ; and barely a grain of the white powder was put to it, and rubbed up with it for about three minutes. When the mercury was poured out of the mortar, it appeared to have acquired a degree of ſpiſſitude, and to be full of lumps ; on ſtraining it through a cloth, an amalgam of a pretty ſolid conſiſtence remained, from which the unmixed mercury was expelled by the flame of a lamp directed by a blow-pipe, as it laid on a piece of charcoal ; and the remainder was a bead of fine metal, which, on ſubſequent trials, appeared to be ſilver. The weight of this bead was eighteen grains, and as much more was ſeparated from the ſtrained mercury as made the whole twenty-nine grains of ſilver ; and the ſilver to the powder as 28 to 1.

“ On the 25th of May, Lords Onſlow, King and Palmerſton ; Sir Robert Barker ; Sir Philip N. Clarke, Bart. the Rev. O'Manning, B. Anderſon, G. Pollin, J. Robinſon, Clerks ; Dr. Spence, W. Mann Godſchall, Wm. Smith, Wm. Godſchall, jun. eſqrs. and Meſſrs. Gregory and Ruſſel, being preſent, the ſixth experiment was made with the uſual precautions and ſimilar ſucceſs, and ſilver obtained in a ſtill larger proportion. And the firſt experiment being alſo again tried, with the variation of placing the mercury in a depreſſion made in a flux of charcoal and borax, pure gold was obtained as before.

“ The author relates two other experiments, made before ſome of the ſame company, on a much larger ſcale ; in which his white powder produced fifty times its weight of ſilver, and his red powder ſixty times its weight in gold : and the produce of theſe experiments, as well as ſome of the former, the author informs us, have been preſented to his majeſty.

“ On reading this very extraordinary publication, it is difficult to avoid falling into thoſe doubts, which the author ſays have been illiberally entertained of the truth of the fact ; yet the evidence is unqueſtionable, and the precautions taken ſuch as ſeem to preclude every poſſibility of deceit. Could it be poſſibly ſuſpected of a gentleman whoſe ſituation in life can by no means render him deſirous of attaining fame by indirect means ? And, as the teſtimony of the fact muſt be admitted without controverſy, he very reaſonably aſks, By what arts of deceit can mercury be prevented from boiling in a red heat ? Or, when actually boiling and evaporating, can it be almoſt inſtantaneouſly fixed by the addition of a ſubſtance not above one 480th of its weight ?

“ On the whole, we might have flattered ourſelves, in the courſe of reading this publication, that many more experiments of the like kind would have been tried, and the facts have received the additional ſanction of ſome learned public ſociety, if we had not unfortunately peruſed the introduction previous to the work ; and, at the cloſe of it, found, to our great mortification, and to the diſappointment of the curious at large, the following paragraph :

“ The whole of the materials, producing the extraordinary change produced in the metal employed, was expended in performing the proceſſes ; nor can the author furniſh himſelf with a ſecond portion, but by a proceſs equally tedious and operoſe ; whoſe effects he has recently experienced to be injurious to his health, and of which he muſt therefore avoid the repetition.”

“ It appears thas Dr. Price, the author of this pamphlet, is a Fellow of the Royal Society, and a phyſician of eminence at Guildford in Surry.”

Theſe ſingular experiments, exhibited ſo repeatedly, and in the preſence of ſuch reſpectable characters, bore the appearance of plauſibility that the tranſmutation of metals was to be obtained. It had long before been tried by various ſcientific gentlemen without effect ; but from the reſult of the above experiments it appeared to be at length accompliſhed. It is no wonder that ſo very ſingular a diſcovery ſhould have engaged the attention of the public at large, but in particular that auguſt body the Royal Society, of which Dr. Price was a member. Theſe diſtinguiſhed amateurs of ſcientific knowledge, deſirous of being ſatiſfied of the truth of what had been aſſerted by ocular demonſtration, requeſted Dr. Price to repeat his experiments in the preſence of the general aſſembly that compoſe that body. This the doctor thought proper to decline ; the conſequence of which was that the Society, being determined to be ſatisfied, laid a peremptory injunction on him that he ſhould comply with their requeſt, on no leſs penalty, in caſe of refuſal, than that of being expelled. This mandate ſtruck the philoſopher to the quick ; his mind was agitated to a degree not to be diſpenſed with, and he ſunk beneath his burthen. Conſcious, no doubt, of the deception he had practiſed on ſo many reſpectable characters, and apprehenſive that a diſcovery would be made ſhould he attempt a repetition before ſo diſcernable a body of people ; at the ſame time reflecting on the irreparable odium that would infallibly fall on him in his expulſion from one of the moſt diſtinguiſhed ſocieties in the kingdom, he knew not what ſtep to take ; till at length, determined not to outlive his ſhame, he formed the dreadful reſolution of terminating his anxiety of mind by putting a period to his exiſtence.

Notwithſtanding the foregoing circumſtances, the Alchemiſts are ſo far from being diſcouraged, that they look for the ſeed of gold not only in baſe metals, but in plants, blood, hair, and even in the very excrements of divers animals with as little ſucceſs.

Thus the celebrated philoſopher the Hon. Mr. Boyle caught the credulous diſtemper ; for he very gravely aſſerts, that the chalk, or earth, which was left at the bottom of an alembic, after a quantity had been diſtilled and re-diſtilled two hundred times, might have been converted into gold.

This mighty change, no doubt, was to be effected in the uſual way by the help of the *powder of projection* ; but herein we are left to think for ourſelves, as the experimentaliſt makes no mention of the proceſs or performance of the operation. And, as was before obſerved, this miraculous powder never was defined, or pretended to be acquired, by any of the adepts in Alchemy ; nor did any of the Alchemiſts ever preſume to ſhew the manner by which the powder operates, except our unfortunate countryman already mentioned.

This art (although generally proſtituted and miſapplied) is not to be finally rejected, or held in contempt, for the reaſons which I ſhall now deduce, and which will corroborate the juſtice of theſe obſerves, notwithſtanding the many legal objections that may be contraſted, or oppoſed, to the whole of this ſyſtem.

1. The artiſt, in his aſſiduous and indefatigable labour to make gold, has frequently ſtumbled upon ſpecific remedies, or medicines, which cure effectually, and ſooner a chronic or ſome other dangerous malady, than a galenical or other preparation uſed by our anceſtors. A diſcovery well worth the moſt laborious and expenſive proceſs, and more to be prized than the acquiſition of a ſecret, which, could it be found, would only ſerve to gratify covetouſneſs, avarice and ambition, three of the worſt paſſions our nature is prone to indulge, inaſmuch as they attend us to the hour of death, though the moſt rare caſe of longevity ſhould be our portion.

But it does not appear that any of thoſe hits have the deſerved name of a panacea, or univerſal medicine, to cure all diſeaſes ; though this is ſo frequently boaſted of by quacks, and other impoſtors, in all countries.

2. The univerſal diſſolvent of Parcelſus and Van Helmont are arguments in favour of this ſyſtem. “ There is (ſay they) a cer-
“ tain fluid in nature capable of reducing all ſublunary bodies, as
“ well homogeneous as mixed into their firſt principle, or original
“ matter of which they are compoſed ; or into an uniform, equal,
“ and portable liquor that will unite with water and the juices of
“ our bodies, yet retain its ſeminal virtues, and if mixed with
“ itſelf again will thereby be converted into pure elementary
“ water.”

Van Helmont is poſitive that he was maſter of that noble menſtruum, and Mr. Boyle conceived ſuch an advantageous opinion of it on his report, that he preferred it to the Philoſopher's Stone. As he (Mr. Boyle) conceived there was not the abſurdity attendant on the notion of an univerſal ens that reſolved all bodies into their general ens ; by freeing them of the heterogeneous particles they were wrapped in ; and thereby reſtore them to their priſtine liberty of directing themſelves, as there is to believe that at the ſame inſtant they are thus freed they acquire another form without the allowance of the leaſt moment for a new direction.

3. No perſon can doubt but that all bodies proceed originally from a firſt matter, which was itſelf once in a fluid ſtate, whoſe particles, by the continual agitation and compreſſion of the atmoſphere, the diverſity of their figures, and the occult quality which directs them to their different poles, have been concatenated together for the formation of thoſe different bodies.

This menſtruum is called the Alkaheſt by the adepts in this ſcience ; the invention of which Van Helmont honours Paracelſus with, who has left the character of it. “ There is (ſays this
“ author) the liquor alkaheſt of great efficacy in preſerving the
“ liver, as alſo in curing hydropical and other diſeaſes ariſing from
“ diſorders of that part. If it has once conquered its like, it
“ becomes ſuperior to all hepatic medicines, and though the liver
“ itſelf were broken and diſſolved, this medicine could ſimply
“ ſupply its place.”

Yet neither Van Helmont, or Paracelſus, has done that juſtice to mankind as to tranſmit ſo valuable a medicine to poſterity, and perhaps the reaſon was, that they might have, in the courſe of their practice, great reaſon to doubt of that ſovereign power above aſcribed to it. Be that as it will, there is great reaſon to doubt of its ſingular efficacy, as ſtated by Van Helmont, agreeable to the maxim, “ he that proves too much is no evidence ;” ſo that to ſubſtitute the Alkaheſt in the place or ſtead of a broken or diſſolved liver, is as far an hyperbole in quackery, as to pretend to reſtore a dead man to life by it. However, I ſhall give this head its due trial, and inform the reader of the particulars.

From the known practice of Paracelſus, he gave names to his remedies by reverſing their real orthography ; hence this word Alkaheſt is formed of the words *alkali* and *eſt*, which is corruptly pronounced Alcal-eſt, or Alkaheſt; conſequently the ſecret medicine is no other than the Alkaline Salt of Tartar volatilized, as Glauber very accurately defines.

It is thus deſcribed by the elder Helmont: “It is the higheſt and moſt ſucceſsful among ſalts, which having obtained the ſupreme degree of ſimplicity, purity and ſubtilty, alone enjoys the faculty of remaining unchanged and unimpaired by the ſubject it works upon, and of diſſolving the moſt ſtubborn and untractable bodies, as ſtones, gems, glaſs, earth, ſulphur, metals, &c. into real ſalt equal in weight to the matter diſſolved; and this with as much eaſe as hot water diſſolves ſnow; and by being ſeveral times cohobated with Parcelſus's ſal circulatum, this ſalt loſes all its fixedneſs, and at length becomes an inſipid water, equal in quantity to the ſalt it was made from.”

Hence we may infer that Parcelſus and Van Helmont, whatever deficiences might be in their Alkaheſt, took water for the univerſal inſtrument of chemiſtry and philoſophy; and earth for the unchangeable baſis of all things; that fire was deſigned as their efficient cauſe; that ſeminal impreſſions were lodged in the mechaniſm of the earth; and that water by diſſolving and fermenting with the earth as it does by means of fire, brings every thing forth; from whence proceed, the Animal, Vegetable, and Mineral kingdoms of nature.

The properties of Alkaheſt are defined under the following operations, viz.

1. It converts the ſubject into a ſubſtance congenial to itſelf, namely, ſaline, ſulphurous and mercurial; then into ſalt alone, which becomes volatile, after which it is turned wholly into an inſipid water.

2. The ſeminal virtues of the bodies thus diſſolved are not deſtroyed. For gold acted upon by this operation is not debaſed into any other ſalt but the ſalt of gold; and in the ſame degree of compariſon are all other metals. Hence an actual and genuine *aurum potabile* might readily be made by the Alkaheſt converting the whole body of gold into ſalt, and making it ſoluble in water without depriving the metal of its ſeminal or radical virtues.

3. The bodies diſſolved by this Alkaheſt may be rendered volatile by a ſand heat: and if after volatizing the ſolvent it be diſtilled therefrom, the body is left pure inſipid water, equal in quantity to its original ſelf, but deprived of its ſeminal virtues.

4. It ſuffers no change or diminution by diſſolving the bodies it works upon, and conſequently ſuſtains no re-action from them, being the only immutable menſtruum in nature.

5. Neither is it capable of mixture; and therefore is free from fermentation and putrefaction, coming off as pure from the body it hath diſſolved as when firſt put thereon, without leaving the leaſt impurity behind.

Such are the properties aſcribed to the Alkaheſt, which is rather an imaginary than a real diſſolvent: a medicine highly deſirable, but no where to be found.

The curious reader who deſires further knowledge on this head is referred to the works of Heliodorus and Syneſius, publiſhed by Fabricius; Boerhaave's Works, tom. I. Alſo to Norton, Ripley, Pearce, Carpenter, Andrews, Chamock, Blomfield, Kelly, Robinſon, Elias, Aſhmole, and Dr. Dee's Works.

ALCHIMELECH, the Egyptian melliot.

ALCHIMELLA, ſynonymous with ALCHEMELLA.

ALCHITRAM, among the alchemiſts, denotes ſometimes the oil of Juniper, ſometimes liquid pitch and ſometimes arſenic, prepared for ablution.

The words, *Alchieram*, *Alchytram*, and *Alkytran*, are ſynonymous of this word.

ALCHOLLEA, a kind of potted fleſh meat, much uſed and admired by the Weſtern Moors; it is firſt pickled, then dried, afterwards boiled, and laſt of all minced and potted.

ALCIBIUM, or ALCIBIADUM, in botany, a word uſed by the ancients to imply a kind of echium, or viper's bugloſs.

ALCMANIAN, in ancient lyric poetry, a kind of verſe conſiſting of two dactyles and two trochees; as,

Virgini | bus pue | riſque | canto.

The word is formed from *Alcman*, the name of an ancient Greek poet, in great eſteem for his erotics or amorous compoſitions.

ALCOHOL, or ALKOOL, in chemiſtry, ſpirit of wine highly rectified. It is alſo uſed for any highly rectified ſpirit. Alcohol is extremely light and inflammable: it is a ſtrong antiſeptic, and therefore employed to preſerve animal ſubſtances.

ALCOHOL is alſo uſed for any fine impalpable powder.

ALCOHOLIZATION, the proceſs of rectifying any ſpirit. It is alſo uſed for pulverization.

ALCOLA is uſed by chemiſts to expreſs the tartar of urine.

ALCOLA is found in three forms, viz.

1. Reſolved, or reduced, into an impalpable ſubſtance.

2. Sandy, or voided, under the appearance of ſmall grains of whitiſh or reddiſh ſand.

3. Mucilaginous, or viſcous.

ALCOR, in aſtronomy, a ſmall ſtar adjoining to the large bright one in the middle of the tail of *urſa major*.

ALCORAN, or AL-KORAN, the ſcripture, or bible, of the Mahometans. The word is compounded of the Arabic particle *al*, and *coran* or *koran*, derived from the verb *caraa* or *karaa*, to read. The word therefore properly ſignifies, *the reading*: or rather, *that which ought to be read*. By this name the Mahometans denote not only the entire book or volumn of the Koran, but alſo any particular chapter or ſection of it; juſt as the Jews call either the whole ſcripture, or any part of it, by the name of *Karah*, or *Mikra*, words of the ſame origin and import.

Beſides this peculiar name, the Koran is alſo honoured with ſeveral appellations common to other books of ſcripture; as, *al Furkan*, from the verb *foraka*, to *divide* or *diſtinguiſh*; not, as the Mahometan doctors ſay, becauſe thoſe books are divided into chapters or ſections, or diſtinguiſh between good and evil; but in the ſame notion that the Jews uſe the word *Perek*, or *Pirka*, from the ſame root, to denote a ſection or portion of ſcripture. It is alſo called *al Moſhaf*, *the volume*, and *al Kitab*, *the book*, by way of eminence, which anſwers to the *Biblia* of the Greeks; and *al Dhikr*, *the admonition*, which name is alſo given to the Pentateuch and Goſpel.

The Koran is divided into 114 larger portions of very unequal length, which we call *chapters*; but the Arabians *ſowar*, in the ſingular *ſura*; a word rarely uſed on any other occaſion, and properly ſignifying a row, order, or a regular ſeries; as a courſe of bricks in building, or a rank of ſoldiers in an army; and is the ſame in uſe and import with the Sura, or Tora of the Jews, who alſo call the fifty-three ſections of the Pentateuch *Sedarim*, a word of the ſame ſignification.

Theſe chapters are not, in the manuſcript copies, diſtinguiſhed by their numerical order, but by particular titles, which are taken ſometimes from a particular matter treated of, or perſon mentioned therein; but uſually from the firſt word of note, exactly in the ſame manner as the Jews have named their Sedarim; though the word from which ſome chapters are denominated be very far diſtant, towards the middle, or, perhaps, the end of the chapter; which ſeems ridiculous. But the occaſion of this appears to have been, that the verſe or paſſage wherein ſuch word occurs, was, in point of time, revealed and committed to writing before the other verſes of the ſame chapter which precede it in order; and the title being given to the chapter before it was completed, or the paſſages reduced to their preſent order, the verſe from whence ſuch title was taken did not always happen to begin the chapter. Some chapters have two or more titles, occaſioned by the difference of the copies, as it is pretended that ſome of the chapters were revealed at Mecca, and others at Medina, the noting this difference makes a part of the title: but the reader will obſerve, that ſeveral of the chapters are ſaid to have been revealed partly at Mecca and partly at Medina; and, as to others, it is yet a diſpute among the commentators to which of the two places they belong.

Every chapter is ſubdivided into ſmaller portions, of very unequal length alſo, which we cuſtomarily call *verſes*: but the Arabic word is *ayat*, the ſame with the Hebrew *ototh*, and ſignifies *ſigns* or *wonders*: ſuch as are the ſecrets of God, his attributes, works, judgements, and ordinances, delivered in thoſe verſes; many of which have their particular titles alſo, impoſed in the ſame manner as thoſe of the chapters.

Beſides theſe unequal diviſions of chapter and verſe, the Mahometans have alſo divided their Koran into ſixty equal portions, which they call *Ahzab*, in the ſingular *Hizb*, each ſubdivided into four equal parts; which is alſo an imitation of the Jews, who have an ancient diviſion of their Miſhna into ſixty portions called Maſſictoth. But the Koran is more uſually divided into thirty ſections only, named *Ajza*, from the ſingular *Joz*, each of twice the length of the former, and in the like manner ſubdivided into four parts. Theſe diviſions are for the uſe of the readers of the Koran in the royal temples, or in the adjoining chapels where the emperors and great men are interred. There are thirty of theſe readers belonging to every chapel, and each reads his ſection every day; ſo that the whole Koran is read over once a-day.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following ſolemn form, by the Mahometans called the *Biſmallah*, in the name of the moſt merciful God; which form they conſtantly place at the beginning of all their books and writings in general, as a peculiar mark or diſtinguiſhing characteriſtic of their religion, it being counted a ſort of impiety to omit it. The Jews, for the ſame purpoſe, make uſe of the form, *In the name of the Lord, or, In the name of the great God*; and the Eaſtern Chriſtians that of, *In the name of the Father, and of the Son, and of the Holy Ghoſt*. But Mahomet probably took this form, as he did many other things, from the Perſian Magi, who uſed to begin their books in theſe words, *Benam Yezdan bakſhaiſhgher dadar*; that is, *In the name of the moſt merciful juſt God*.

There are twenty-nine chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet, ſome with a ſingle one, others with more. Theſe letters the Mahometans believe to be the peculiar marks of the Koran, and to conceal ſeveral profound myſteries; the certain underſtanding of which, the more intelligent confeſs, has not been communicated to any mortal, their prophet only excepted. Notwithſtanding which, ſome will take the liberty of gueſſing at their meaning by that ſpecies of Cabala called by the Jews Notarikon, and ſuppoſe the letters to ſtand for as many words, expreſſing the names and attributes of God, his works, ordinances, and decrees; and therefore theſe myſterious letters, as well as the verſes themſelves, ſeem in the Koran to be called ſigns. Others explain the intent of theſe letters from their nature or organ, or elſe from their value in numbers, according to another ſpecies of the Jewiſh Cabala, called Gematria; the uncertainty of which conjectures ſufficiently appears from their diſagreement.

The Koran is univerſally allowed to be written with the utmoſt elegance and purity of language, in the dialect of the tribe of Koreiſh, the moſt noble and polite of all the Arabians, but with ſome mixture, though very rarely, of other dialects. It is confeſſedly the ſtandard of the Arabic tongue, and, as the more orthodox believe, and are taught by the book itſelf, inimitable by any human pen; and therefore inſiſted on by the Mahometans as a permanent miracle, greater than that of raiſing the dead.

To this did Mahomet himſelf chiefly appeal for the confirmation of his miſſion, publicly challenging the moſt eloquent men in Arabia, which was at that time ſtocked with thouſands whoſe ſole ſtudy and ambition it was to excel in elegance of ſtyle and compoſition, to produce even a ſingle chapter that might be compared with it.

To the pomp and harmony of expreſſion ſome aſcribe all the force and effect of the Alcoran; which they conſider as a ſort of muſic, equally fitted with other ſpecies of that art to raviſh and amaze.

In this Mahomet ſucceeded ſo well, and ſo ſtrangely captivated the minds of his audience, that ſeveral of his opponents thought it the effect of witchcraft and enchantment, as he himſelf complains. Others have attributed the effect of the Alcoran to the frequent mention of rewards and puniſhments; heaven and hell occurring almoſt in every page.

The general deſign of the Koran, the impoſtor pretended was to unite the profeſſors of the three different religions, then followed in the populous country of Arabia, Pagans, Jews, and Chriſtians, in the knowledge and worſhip of one God, under the ſanction of certain laws, and the outward ſigns of ceremonies partly of ancient and partly of novel inſtitution, enforced by the conſideration of rewards and puniſhments both temporal and eternal; and to bring them all to the obedience of Mahomet, as the prophet and ambaſſador of God, who, after the repeated admonitions, promiſes, and threats, of former ages, was at laſt to eſtabliſh and propagate God's religion on the earth, and to be acknowledged chief pontiff in ſpiritual matters, as well as ſupreme prince in temporal.

The great doctrine then of the Koran, is the unity of God; to reſtore which point Mahomet pretended was the chief end of his miſſion; it being laid down by him as a fundamental truth, that there never was, nor ever can be, more than one true orthodox religion. For though the particular laws or ceremonies are only temporary, and ſubject to alteration, according to the divine direction, yet the ſubſtance of it being eternal truth, is not liable to change, but continues immutably the ſame.

And he taught, that, whenever this religion became neglected, or corrupted in eſſentials, God had the goodneſs to re-inform and re-admoniſh mankind thereof, by ſeveral prophets, of whom Moſes and Jeſus were the moſt diſtinguiſhed, till the appearance of Mahomet, who is their ſeal, and no other to be expected after him.

The more effectually to engage people to hearken to him, great part of the Koran is employed in relating examples of dreadful puniſhments formerly inflicted by God on theſe who rejected and abuſed his meſſengers; ſeveral of which ſtories, or ſome circumſtances of them, are taken from the Old and New Teſtaments, but many more from the apocryphal books and traditions of the Jews and Chriſtians of thoſe ages, ſet up in the Koran as truths in oppoſition to the Scriptures, which the Jews and Chriſtians are charged with having altered: and indeed, few or none of the relations or circumſtances in the Koran were invented by Mahomet, as is generally ſuppoſed, it being eaſy to trace the greateſt part of them much higher.

The reſt of the Alcoran is taken up in preſcribing neceſſary laws and directions, frequent admonitions to moral and divine virtues, the worſhip reverence of the Supreme Being, and reſignation to his will. One of their moſt learned commentators diſtinguiſhes the contents of the Alcoran into allegorical and literal; under the former are comprehended all the obſcure, parabolical, and enigmatical paſſages, with ſuch as are repealed or abrogated; the latter, ſuch as are clear and in full force.

The moſt excellent moral in the whole Alcoran, interpreters ſay, is in the chapter *Al Alraf*, viz. Shew mercy, do good to all, and diſpute not with the ignorant; or, as Mr. Sale renders it, uſe indulgence, command that which is juſt, and withdraw far from the ignorant. Mahomet, according to the authors of the Keſchaf, having begged of the angel Gabriel a more ample explication of this paſſage, received it in the following terms: "Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your ſouls the roots of his chief perfections." It is eaſy to ſee that this commentary is copied from the Goſpel. In reality, the neceſſity of forgiving enemies, though frequently inculcated in the Alcoran, is of a later date among the Mahometans than among the Chriſtians; among thoſe latter, that among the Heathens; and to be traced originally among the Jews.

It is the general and orthodox belief among the Mahometans, that the Koran is of Divine original; nay, that it is eternal and uncreated, remaining, as ſome expreſs it, in the very eſſence of God: that the firſt tranſcript has been from everlaſting by God's throne, written on a table of vaſt bigneſs, called the preſerved table, in which are alſo recorded the divine decrees paſt and future: that a copy from this table, in one volume on paper, was, by the miniſtry of the angel Gabriel, ſent down to the loweſt heaven, in the month of Ramadan, on the night of power: from whence Gabriel revealed it to Mahomet by parcels, ſome at Mecca, and ſome at Medina, at different times, during the ſpace of 23 years, as the exigency of affairs required; giving him, however, the conſolation to ſhow him the whole (which they tell us was bound in ſilk, and adorned with gold and precious ſtones of paradiſe) once a year; but in the laſt year of his life he had the favour to ſee it twice. They ſay, that few chapters were delivered entire, the moſt part being revealed piecemeal, and written down from time to time by the prophet's amanuenſis in ſuch a part of ſuch and ſuch a chapter, till they were completed, according to the directions of the angel. The firſt parcel that was revealed is generally agreed to have been the firſt five verſes of the 96th chapter.

When Mahomet died, he left his revelations in diſorder, and not digeſted into the method, ſuch as it is, in which we now find them. This was the work of his ſucceſſor Abu Beer; who, conſidering that a great number of paſſages were committed to the memory of Mahomet's followers, many of whom were ſlain in their wars, ordered the whole to be collected, not only from the palm-leaves and ſkins on which they had been written, and which were kept between two boards or covers, but alſo from the mouths of ſuch as had gotten them by heart. This tranſcript, when completed, he committed to the cuſtody of Haſſa the daughter of Gmar, one of the prophet's widows.

In the 30th year of the Hegira, Othman being then caliph, and obſerving the great diſagreement in the copies of the Koran in the ſeveral provinces of the empire; thoſe of Irak, for example, following the reading of Abu Muſa al Aſhari, and the Syrians that of Macdad Ebn Eſwad; he, by the advice of the companions, ordered a great number of copies to be tranſcribed from that of Abu Beer, in Haſſa's care, under the inſpection of Zeid Ebn Thabet, Abd'allah Ebn Zobair, Said Ebn al As, and Ad'alrahman Ebn al Hareth the Makhzumite; whom he directed, that, wherever they diſagreed about any word, they ſhould write it in the dialect of the Koreiſh, in which it was at firſt delivered. Theſe copies, when made, were diſperſed in the ſeveral provinces of the empire, and the old ones burnt and ſuppreſſed.

The Alcoran is held in the higheſt eſteem and reverence among the Muſſulmen. They dare not ſo much as touch the Alcoran without being firſt waſhed, or legally purified; to prevent which, an inſcription is put on the cover or label, *Let none touch, but thoſe who are clean.*

Mahomet fabricated a ſyſtem of incoherence, a religion of depravity totally repugnant to the nature of that being, who, as he pretended, was its object; but therefore more likely to accord with the appetites and conceptions of a corrupt and ſenſual age.

Alçoran is alſo figuratively applied to certain other books full of impieties and impoſtures. In this ſenſe we meet with the Alcoran of the Cordeliers, which has made a great noiſe; wherein St. Francis is extravagantly magnified, and repreſented as more than mortal.

ALCORANISTS, among Mahometans, thoſe who adhere ſtrictly to the letter or text of the alcoran, from an opinion of its ultimate ſufficiency and perfection. ThePerſians are generally Alcoraniſts, as admitting the Alcoran alone for their rule of faith. The Turks, Tartars, Arabs, &c. beſides the Alcoran, admit as multitude of traditions.

ALCOVE, among builders, a receſs, or part of a chamber ſeparated by an eſtrade, or partition of columns, and other correſponding ornaments, in which is placed a bed of ſtate, and ſometimes ſeats to entertain company.

ALCYON, the trivial name of a ſpecies of alcedo.

ALCYONIUM, an obſolete name of a ſubmarine plant. It is alſo uſed for a kind of coral, or aſtroites, frequently found foſſile in England.

ALDABARAM, in anatomy, a name given to the ſeſamoide bones in the great toe.

ALDARU, in botany, ſignifies the Lentiſk tree of many authors.

ALDEBAC, in medicine, implies the ancient vegetable poiſon, which modern authors ſuppoſe to be the ſame as bird-lime.

ALDEBARAN, in aſtronomy, a ſtar of the firſt magnitude, called in Engliſh the bull's eye, as making the eye of the conſtellation Taurus. Its longitude is 6 deg. 32 min. 9 ſec. of Gemini, and its latitude 5 deg. 29 min. 40 ſec. ſouth.

ALDER Tree, in botany, ſynonymous with Betula.

ALDER-Berry-Bearing, is ranked in the Pentandria claſs, Monogynia; order and genus of Rhamnus; and conſiſts of two ſpecies; for its characters, ſee Syſtem of BOTANY.

ALDERAIMIN, in aſtronomy, is a ſtar of the third magnitude, on the right ſhoulder of the conſtellation Cepheus.

ALDERMAN, in the Britiſh policy, a magiſtrate ſubordinate to the lord mayor of a city or town-corporate. The number of theſe magiſtrates is not limited, but is more or leſs according to the magnitude of the place. In London they are 26; each having one of the wards of the city committed to his care. This office is for life; ſo that when one of them dies, or reſigns, a wardmote is called, who return two perſons, one of whom the lord-mayor and aldermen chooſe to ſupply the vacancy. All the aldermen are juſtices of the peace, by a charter of 15 Geo. II.

The aldermen of London, &c. are exempted from ſerving inferior offices; nor ſhall they be put upon aſſizes, or ſerve on juries, ſo long as they continue to be aldermen.

ALDERMAN, among our Saxon anceſtors, was a degree of nobility anſwering to our preſent earl or count.

ALDERMAN was alſo uſed, in the time of king Edgar, for a judge or juſtice. Thus we meet with the titles of *Aldermannus totius Angliæ, aldermannus regis, comitatus, civitatis, burgi, caſtelli, hundredi ſive wapentachii, et novemdecimorum.* According to Spelman, the *aldermannus titius Angliæ* ſeems to have been the ſame officer who was afterwards ſtyled *capitalis juſticiarius Angliæ*, or chief juſtice of England; the *aldermannus regis* ſeems to have been an occaſional magiſtrate, anſwering to our juſtice of aſſize; and the *aldermannus comitatus*, a magiſtrate who held a middle rank between what was afterwards called the *earl* and the *ſheriff*; he ſat at the trial of cauſes with the biſhop: the latter proceeding according to eccleſiaſtical law, and the former declaring and expounding the common law of the land.

ALDHAFERA, in the Arabian ſyſtem of aſtronomy, denotes a fixt ſtar of the third magnitude in the lion's mane.

ALDII, in antiquity, implied ſervants who attended their maſters in expeditions to the wars.

ALDROVANDIA, in botany, a genus of the pentandria order, belonging to the pentagynia claſs of plants; of which there is but one ſpecies. The calyx is divided into five parts; the petals are five; and the capſule has five valves, with ten ſeeds. It is a native of Italy and the Indies; and has no Engliſh name.

ALE, a fermented liquor obtained from an infuſion of malt, and differing from beer chiefly in having a leſs proportion of hops.

This liquor, the natural ſubſtitute of wine in ſuch countries as could not produce the grape, was originally made in Egypt, the firſt planted kingdom, on the diſperſion from the Eaſt, that was ſuppoſed unable to produce grapes. And, as the Noachian colonies pierced further into the weſt, they found, or thought they found, the ſame defect, and ſupplied it in the ſame manner.

Thus the natives of Spain, the inhabitants of France, and the aborigines of Britain, all uſed an infuſion of barley for their ordinary liquor: and it was called by the various names of Cælia and Ceria in the firſt country, Cereviſia in the ſecond, and Curmi in the laſt; all literally importing only *the ſtrong water*. See Syſtem of BREWING.

"All the ſeveral nations (ſays Pliny) who inhabit the weſt of Europe, have a liquor with which they intoxicate themſelves, made of corn and water. The manner of making this liquor is ſomewhat different in Gaul, Spain, and other countries, and is called by many various names; but its nature and properties are every where the ſame. The people of Spain, in particular, brew this liquor ſo well, that it will keep good a long time. So exquiſite is the cunning of mankind, in gratifying their vicious appetites, that they have thus invented a method to make water itſelf intoxicate."

The method in which the ancient Britons, and other Celtic nations, made their ale, is thus deſcribed by Iſidorus and Oroſius. "The grain is ſteeped in water and made to germinate, by which its ſpirits are excited and ſet at liberty; it is then dried and grinded; after which it is infuſed in a certain quantity of water; which being fermented, becomes a pleaſant, warming, ſtrengthening, and intoxicating liquor." This ale was moſt commonly made of barley; but ſometimes of wheat, oats, and millet.

Anciently the Welch and Scots had alſo two kinds of ale, called *common ale* and *ſpiced ale*; and their value was thus aſcertained by law:

"If a farmer hath no mead, he ſhall pay two caſks of ſpiced ale, or four caſks of common ale, for one caſk of mead." By this law, a caſk of ſpiced ale, nine palms in height, and 18 palms in diameter, was valued at a ſum of money equal in efficacy to ſeven pounds ten ſhillings of our preſent money; and a caſk of common ale, of the ſame dimenſions, at a ſum equal to three pounds fifteen ſhillings.

This is a ſufficient proof, that even common ale, in this period, was an article of luxury among the Welch, which could only be obtained by the great and opulent.

Wine ſeems to have been quite unknown, even to the kings of Wales in this period; as it is not ſo much as once mentioned in their laws; though Giraldus Cambrenſis, who flouriſhed about a century after the conqueſt, acquaints us, that there was a vineyard in his time at Maenarper, near Pembroke, in South Wales.

Ale was the favourite liquor of the Anglo-Saxons and Danes, as it had been of their anceſtors the ancient Germans. Before their converſion to Chriſtianity, they believed that drinking large and frequent draughts of ale was one of the chief felicities which thoſe heroes enjoyed who were admitted into the hall of Odin.

There are various ſorts of ale known in Britain, particularly pale and brown: the former is brewed from malt ſlightly dried; and is eſteemed more viſcid than the latter, which is made from malt more highly dried or roaſted.

Pale ale brewed with hard waters, as thoſe of ſprings and wells, is judged the moſt wholeſome, in regard the mineral particles tend to prevent the coheſions of thoſe drawn from the grain, and enable them to paſs the proper ſecretions the better; ſofter waters, as thoſe of rivers, and rain, ſeem better ſuited to draw out the ſubſtance of high-dried malts, which retain many igneous particles beſt abſorbed in a ſmooth vehicle.

Ale is prepared various ways, and of various ingredients, as of wheat, rye, millet, oats, barley, the berries of the quick bean, &c.

Ale is generally held to be more diuretic than beer, in regard it is ſmoother, more ſoftening, and relaxing; ſo that where urine is to be promoted by facilitating the peſſage, ale is moſt likely to effect it.

Ale is flatulent; and hence ſometimes produces colics; and the cholera morbus: it is aceſcent; but it does not produce calcareous diſeaſes, as has been aſſerted.

If malt liquor, of any degree of ſtrength, is become flat and tartiſh, as it is uſed, it ſhould be drawn out of the caſk into a jug, in which as many drams of powdered chalk is put as there are to be pints of liquor: thus a new ferment will be raiſed, a ſprightly taſte will be reſtored to the liquor, and its acidity will be deſtroyed. Tart liquors of this kind are apt to produce a dyſury, ſtrangury, or a gonorrhœa; in which caſes, a ſmall quantity of brandy may be taken.

The duties on ale and beer make a principal branch of the revenue in Britain. They were firſt impoſed by the 12th of Car. II. and have been continued by ſeveral ſubſequent acts of parliament to firſt Geo. III. which lays an additional duty of 3d. per barrel. In the whole, the brewer of ale and beer for ſale ſhall pay 8s. for every barrel of either, above 6s. a barrel; and for every barrel of 6s. or under, the ſum of 1s. 4d.

Medicated ALES, thoſe wherein medicinal herbs have been infuſed, or added during the fermentation.

Gill ALE is that in which the dried leaves of gill or ground-ivy have been infuſed. It is eſteemed abſterſive and vulnerary, and conſequently good in diſorders of the breaſt and obſtructions of the viſcera.

ALE-*Conner*, an officer in London, who inſpects the meaſures uſed in public houſes. There are four ale-conners, who are all choſen in the common-council of the city.

ALE-*Houſes* muſt be licenſed by juſtices of the peace, who take recognizances of the perſons licenſed, and of their ſureties, viz. 10l. each, that they will not ſuffer unlawful gaming, or other diſorderly practices in their houſes. Every perſon, excepting thoſe who ſell ale in fairs, neglecting to procure a licence, is liable to a penalty of 40s. for the firſt offence, 4l. for the ſecond, and 6l. for the third, with all coſts. The licence is granted on the firſt of September, or within twenty days after, at a general meeting of the juſtices for the diviſion to which he belongs, upon his producing a certificate to his character, unleſs, by living in a city or town-corporate, this laſt circumſtance is diſpenſed with, and continues in force for one year only. Ale-houſe keepers, ſelling ale in ſhort meaſure, are liable to a penalty not exceeding 40s. and not leſs than 10s. and likewiſe to a fine of 10s. for permitting tipling, &c.

By 29th Geo. II. c. 12. perſons keeping ale houſes in Scotland ſhall be licenſed as in England, and the juſtices there ſhall meet annually to licenſe ale-houſes; on each of which licenſes a fee of 1s. is payable to the clerk of the peace. Magiſtrates of royal boroughs ſhall meet yearly for the like purpoſe; but where there ſhall not be a ſufficient number of magiſtrates to act in any royal borough, juſtices may grant licenſes, to be in force for one year only.

Perſons in Scotland convicted of keeping unlicenſed ale-houſes ſhall forfeit for the firſt offence 5s. for the ſecond 10s. for the third 20s. and to be diſqualified; and for every ſubſequent offence 40s. to be levied by diſtreſs and ſale, one moiety to the informer, the other to the poor of the pariſh. Conviction to be intimated to the offender, and certified to the clerk of the peace, and recorded: but perſons aggrieved may appeal to the quarter ſeſſions.

Licenſes for houſes on the military roads in Scotland ſhall be iſſued on payment of 1s. only to the clerk of the peace: making out licenſes before the ſame be ſtamped, is a penalty of 10l. and making them contrary to the intention of this act, 5l. and the ſame ſhall be vacated, unleſs the duty and fine be paid, and the receipt produced, and licence ſtamped.

ALE-*Silver*, a tax paid annually to the lord-mayor of London, by all who ſell ale within the city.

ALEA, in Roman antiquity, ſignifies generally all manner of games of chance; but, in a more reſtricted ſenſe, implies particular game played with dice and tables, not unlike our backgammon.

ALEATORIUM, in Roman antiquity, denoted the place where the game of Alea was played.

ALEC, in ichthyology, the name of a fiſh of the ſparus kind.

ALECOST, ſynonymous with Tanzy.

ALECTO, in mythology, one of the furies, daughter of Acheron and Night, or, as ſome ſay of Pluto and Proſerpine.

ALECTORIA, in natural hiſtory, a ſtone ſaid to be formed in the gall-bladders of old cocks, to which the ancients aſcribed many fabulous virtues. This is otherwiſe called *Alectorius Lapis*, ſometimes *Alectorolithos*, in Engliſh the *cock-ſtone*. The more modern naturaliſts hold the *alectorius lapis* to be originally ſwallowed down, not generated in, the ſtomach or gizzard of cocks and capons. It is known that many of the fowl-kind make a practice of ſwallowing pebbles, as it is ſuppoſed to be of ſervice in the buſineſs of trituration and digeſtion.

ALECTOROMANTIA, in antiquity, a ſpecies of divination performed by means of a cock. This is otherwiſe called *Alectryomancy*; of which there appear to have been different ſpecies. But that moſt ſpoken of by authors was in the following manner: a circle being deſcribed on the ground, and divided into twenty-four equal portions, in each of theſe ſpaces was written one of the letters of the alphabet, and on each of the letters was laid a grain of wheat; after which, a cock being turned looſe in the circle, particular notice was taken of the grains picked up by the cock, becauſe the letters under them, being formed into a word, made the anſwer deſired. It was thus, according to Zonoras, that Libanus and Jamblicus ſought who ſhould ſucceed the emperor Valens; and the cock eating the grains anſwering to the ſpaces ΘΕΟΔ, ſeveral whoſe names began with thoſe letters, as Theodotus, Theodiſtes, Theodulus, &c. were put to death; which did not hinder, but promote, Theodoſius to the ſucceſſion. But the ſtory, however current, is but ill ſupported: it has been called in queſtion by ſome, and refuted by others, from the ſilence of Marcellinus, Socrates, and other hiſtorians of that time.

A-LEE, in the ſea-language, a term only uſed when the wind, croſſing or flanking the line of a ſhip's courſe, preſſes upon the maſts and ſails ſo as to make her incline to one ſide, which is called the lee-ſide: hence, when the helm is moved over to this ſide, it is ſaid to be *a-lee*, or *hard-a-lee*.

ALEGER, a name given to an inferior ſort of vinegar made from malt liquor inſtead of wine.

ALEMBDAR, or ALEMDAR, an officer in the court of the Grand Signior, who bears the green ſtandard of Mahomet, when the ſultan appears in public on any ſolemn occaſion.

ALEHOOF, in botany, a name given to ground ivy.

ALEIPHA, in the materia medica, implies a general name for fatted bodies both in the animal and vegetable kingdoms of nature. But, in a more reſtricted ſenſe, ſignifies all ointments that are uſed to rub the human body with, in order to relieve the patient by abſorption through the pores of the ſkin. The word is purely Greek, from *αλειφε, I anoint*.

ALEMBIC, or LEMBEC, a chemical veſſel, uſually made of glaſs or copper, formerly uſed for diſtillation. The bottom part, which contained the ſubject for diſtillation, is called, from its ſhape, the *cucurbit*; the upper part, which receives and condenſes the ſteam, is called the head, the beak of which is fitted into the neck of a receiver. Retorts, and the common worm-ſtill, are now more generally employed in diſtillation.

ALEMBROTH, in the writings of the alchemiſts, a word uſed for a ſort of fixed alkaline ſalt, which had the power of the famous alkaheſt, in diſſolving bodies, opening the pores of moſt or all known ſubſtances, and thence, as well as by deſtroying ſulphurs, promoting the ſeparation of metals from their ores. It is alſo uſed for a compound of corroſive mercury and ſal ammoniac.

ALERON, in ancient medicine, ſignified the oil of ſweet almonds.

ALEORE, from *αλεωρη*, in the materia medica of the ancients, implied the intermiſſion of eaſe, from the raging pains of any acute or violent diſtemper.

ALERION, in heraldry, a ſynonomy of Allerion.

ALES, in a general ſenſe, ſignifies a name given to a compound ſalt. But in a particular application it implies contracted, when uſed by the faculty as an adjective.

ALETON, from *αληω, to grind*, implies meal produced from any ſort of corn ground in a mill.

ALETIDES, in mythology, denoted the ſacrifices offered by the Athenians to Icarius and Erigone. The former was ſlain by the ſhepherds of Attica, who imagined they were poiſoned by drinking ſome wine he had given them. The latter, on finding her father was dead, flew herſelf to accompany him in elyſium. The Delphian oracle inſtituted this worſhip to appeaſe the ghoſts of the unfortunate father and daughter.

ALETRIS, in botany, a genus of the monogynia order belonging to hexandria claſs of plants, and in the natural method ranking under the 10th order Coronariæ. For the character, ſee Syſtem of BOTANY.

Of this genus there are five ſpecies, all of which are exotics that cannot live in this country.

The Aletris is generally defined as the Baſtard Aloe.

ALEUCOMANCY, is formed of the Greek words, *αλευρον, meal*, and *μαντεια, divination*, which is the ſame with what was otherwiſe called *alphitomantia* and *crithomanthia*, and means an ancient kind of divination performed by means of meal or flour.

ALEXANDRIAN, in a general ſenſe, was applied to thoſe who taught ſchool in Alexandria: or at leaſt were profeſſors of the ſciences: hence Clemens, Apion, Oaſis, and Aroſtarchus, as well as the celebrated Philoſephus, Amonius, Plotinus, Origen, Porphyry, Jamblicus, Sopater, Maximus, and Dexippus, are called Alexandrians.

ALEXANDRIAN is more particularly underſtood of a college of prieſts, conſecrated to the ſervice of Alexander Severus after his deification. Lampridius relates, that, notwithſtanding Severus was killed by Maximin, the ſenate proſecuted his apotheoſis; and, for regularity of worſhip, founded an order of prieſts, or *ſodales*, under the denomination of *Alexandrini*.

ALEXANDRIAN MANUSCRIPT, a famous copy of the Scriptures, conſiſting of four volumes, in a large quarto ſize; which contains the whole Bible in Greek, including the Old and New Teſtament, with the Apocrypha, and ſome ſmaller pieces, but not quite complete.

This manuſcript is now preſerved in the Britiſh Muſeum. It was ſent as a preſent to king Charles I. from Cyrillus Lucaris, patriarch of Conſtantinople, by Sir Thomas Rowe, ambaſſador from England to the Grand Signior, about the year 1628. Cyrillus brought it with him from Alexandria, where probably it was written.

In a ſchedule annexed to it, he gives this account: That it was written, as tradition informed them, by Thecla, a noble Egyptian lady, about 1300 years ago, not long after the council of Nice.

But this high antiquity, and the authority of the tradition to which the patriarch refers, have been diſputed; nor are the moſt accurate biblical writers agreed about its age.

Grabe thinks that it might have been written before the end of the fourth century; others are of opinion, that it was not written till near the end of the fifth century, or ſomewhat later.

ALEXANDRIAN, or ALEXANDRINE, in poetry, a kind of verſe conſiſting of twelve, or of twelve and thirteen ſyllables alternately; ſo called from a poem on the life of Alexander, called the Alexandriad, written in this kind of verſe by ſome French poet. Alexandrines are peculiar to modern poetry, and ſeem well adapted to epic poems. They are uſed by moſt nations of Europe; but chiefly by the French, whoſe tragedies are generally compoſed of Alexandrines.

ALEXICACUS, ſomething that preſerves the body from harm or miſchief. The word ſignifies the ſame as *alexiterial*.

ALEXICACUS, in mythology, was an attribute of Neptune, whom the tunny-fiſhers uſed to invoke under this appellation, that their nets might be preſerved from the ſword-fiſh, which uſed to tear them; and that he might prevent the aſſiſtance which it was pretended the dolphins uſed to give the tunnies on this occaſion.

ALEXIPHARMICS, in medicine, are properly remedies for expelling or preventing the ill effects of poiſon: but ſome of the moderns having imagined, that the animal ſpirits, in acute diſtempers, were affected by a malignant poiſon, the term has been underſtood to mean medicines adapted to expel this poiſon by the cutaneous pores, in the form of ſweat. In this ſenſe, alexipharmics are the ſame as ſudorifics.

ALEXITERIAL, among phyſicians, a term of much the ſame import with *alexipharmic*; though ſometimes uſed in a ſynonymous ſence with amulet.

ALFANDICA, the name of the cuſtom-houſe at Liſbon.

ALFAQUES, among the Moors, the name generally uſed for their clergy, or thoſe who teach the Mahometan religion; in oppoſition to the Morabites, who anſwer to monks among Chriſtians.

ALFDOUCH, a name given by the Moors to a ſort of vermicelli, which they make of flour and water, and are very fond of in their entertainments.

ALFECCA, in aſtronomy, a name given to the ſtar, called Lucida Coronæ, or Alſeta.

ALFEET, in antiquity, denoted a caldron full of boiling water, wherein an accuſed perſon, by way of trial or purgation, plunged his arm up to the elbow.

ALGA, in botany, ſignifies the trivial name of the lichen, fucus, and ſeveral other plants of the Cyptogamia claſs.

ALGÆ, FLAGS, or FLAGGERS, form one of the ſeven families of plants in the Linnæan ſyſtem, in which they conſtitute the 3d order of the 24th claſs. See Syſtem of BOTANY, for the characters of this diſtribution in the vegetable kingdom.

ALGALI, an obſolete term in chemiſtry for nitre.

ALGAROL, or ALGAREL, in chemiſtry, implies an Arabic term for an emetic powder, prepared from regulus of antimony diſſolved in acids, and ſeparated by repeated lotions in warm water.

ALGATRANE, a ſort of pitch found in the Bay, formed by the point of St. Helena on the ſouth of the iſle of Plata.

ALGAVAREIA, the ancient language of the Moors who ſettled in Spain, a kind of barbarous dialect of the Arabic, contradiſtinguiſhed from the Adjameia, or real Moriſco, ſpoken in Morocco.

ALGEBRA, in a general ſenſe, implies the method of reſolving problems by equation. For further particulars, ſee New Syſtem of ALGEBRA.

A NEW SYSTEM of ALGEBRA.

ALGEBRA is an art or ſcience of univerſal uſe in mathematics, teaching in a general manner to ſolve difficult Problems, and to diſcover and inveſtigate Propoſitions and Theorems in any particular branch of Science, by comparing, with one another, the relation of the abſtract quantities therein concerned.

It is an art truly ſublime, and of an unlimited extent; for though the nature of the ſubject, to which it is applied, ſhould be ever ſo complex; and the quantities concerned ſhould be ever ſo much entangled, yet it affords means of ſurmounting the utmoſt difficulties, and, by a curious and careful purſuit through the moſt intricate labyrinths, of attaining to the anſwer ſought.

In this art letters or ſymbols are ſubſtituted in the place of numbers, and thereby it obtains an eminent advantage over mere arithmetical operations; becauſe there the numbers become, as it were, metamorphoſed and changed into others; whereas here the quantities are preſerved diſtinct, viſible, and unchanged, from which general rules may be drawn for anſwering all queſtions of a ſimilar nature with that under conſideration.

On account of its extent and uſefulneſs it has been named UNIVERSAL MATHEMATICS, UNIVERSAL ARITHMETIC, and, by way of eminence, *Ars Magna*, or the GREAT ART. In Arabic, it is called *Algiabr Walmokabala*, which ſignifies the *Art* of *Reſtitution* and *Compariſon*, or the *Art* of *Reſolution* and *Equation*; and it is highly probable that it was from the former word, *Algiabr*, that we derived the name Algebra. It is alſo called *Specious Arithmetic*, the *Analitic Art*, &c. And from its wonderful diſpatch and brevity, and uſe of ſymbols, it may likewiſe, with propriety, be termed MATHEMATICAL STENOGRAPHY.

The firſt inventor of this noble art is not certainly known: however, it is highly probable the ancients had ſome ſort of Analyſis, whereby they found out moſt of their excellent Theorems; for it is hardly poſſible to conceive that they could have hit upon them otherwiſe; and indeed there are ſome examples of it in Euclid, at leaſt in *Theon upon Euclid*, who ſays, that the art was firſt communicated by Plato: and hence Plato is by many eſteemed the inventor. There are alſo inſtances of it in *Pappus*, and the effects thereof are diſcoverable in *Archimedes*, *Apollonius*, and others, though they appear to have ſtudiouſly diſguiſed it.

This art however is ſaid to have been in uſe among the Arabs much earlier than among the Greeks, and even they are ſuppoſed to have borrowed it from the Perſians, who alſo, it is conjectured, learned it of the Indians.

It is further aſſerted, that it was firſt introduced into Europe by means of an emigration of the Arabs into Spain, about the beginning of the twelfth century; whence ſome are of opinion, it came into England before Diophantus, who wrote profeſſedly on the art, in or about the third century, was known among us. Diophantus's Treatiſe conſiſted of thirteen books, ſix of which were tranſlated from the Greek into Latin, and publiſhed by Xylander in 1575. He is recorded to be the firſt Grecian who wrote on the ſubject. His works only treat of indeterminate Problems.

In 1494, Lucas Pacciolus, or Lucas de Burgo, a Minorite friar, publiſhed at Venice a Treatiſe of Algebra in Italian. This author mentions Leonardus Pſanus, and ſome others, of whom he had learned the art. He eſtabliſhes the received opinion that Algebra came originally from the Arabs, and takes no notice of Diophantus, which makes it probable that that author's works were not then known in Europe. Pacciolus's Treatiſe goes no farther than Quadratic Equations.

Stefelius, Scipio Ferreus, Cardan, and Tartagilla, ſucceeded each other, and gave ſome ſolutions of Cubic Equations.

Next came Bombelli, Nunninus, Romus, Schoner, Salignac, Clavius, and ſome others; but none of them went beyond Quadratics.

About the year 1590, Vieta publiſhed his Syſtem of Algebra, wherein he gave an ingenious method of extracting the Roots of Equations by approximations, which has ſince been greatly improved by Raphſon, Halley, Simpſon, Emerſon, and others.

In 1631, Oughtred and Harriot publiſhed their Treatiſes, both of which were well received.

The celebrated Des Cartes, in 1657, publiſhed his Geometry, wherein he introduced the algebraic Rules of Harriot, and applied them to the higher Geometry, explaining the nature of Curves by Equations, and adding the Conſtruction of Cubics, Biquadratic, and other higher Equations.

Sluſius in 1668, Fermat in 1669, and Barrow in 1670, with ſeveral other authors, improved upon Des Cartes's plan; but none with greater ſucceſs than Thomas Baker in 1684, and Dr. Wallis in 1685. However, as an elementary writer, no author can be more deſerving of praiſe than Kerſey, who publiſhed the firſt Engliſh Treatiſe of Algebra, wherein the nature of Equations are largely explained and illuſtrated by a variety of Examples. The whole ſubſtance of Diophantus is alſo delivered, and many things added concerning Mathematical Compoſition and Reſolution from Ghetaldus.

Preſlet in 1694, Ozanam in 1703, Guiſne in 1704, and L'Hoſpital in 1707, publiſhed with ſucceſſive improvements.

The immortal Engliſh Philoſopher, Sir Iſaac Newton, publiſhed his *Arithmetica Univerſalis*, this year, 1707, which abounds in ſelect Examples, and cóntains ſeveral Rules and Methods invented by the author.

Algebra has been ſince applied to a world of Knowledge, ſurpaſſing all the wiſdom of the ancients, namely, the conſideration and calculous of Infinites, called generally the Doctrine of Fluxions. It is alſo named *Analyſis of Infinites*; and the *Calculus Differentialis*.

Of a modern date, the number of Algebraical authors is almoſt incredible. I muſt however, with deference to the hoſt, name thoſe whom I think the moſt intelligent and uſeful, viz. Saunderſon, Ward, Simpſon, Emerſon, and Maclaurin; but, as a ſchool book, the Treatiſe of Bonnycaſtle is well adapted. He is exceeding methodical, and elegant in his text; and ſo indeed he is in every thing that he has committed to the preſs.

Having, in as brief a manner as I was able, given an hiſtoric view of the rice and progreſs of the art, I ſhall proceed to ſhew the rudiments thereof, by touching on the ſeveral methods whereby Algebraical Operations are principally performed.

I am well aware that the application of Algebra preſents a wide field to the man of ſcience, as well as to the young artiſt, who thirſts for knowledge, ſo that it remains neceſſary to obſerve that thoſe numerous matters cannot be expected to come within the limits appointed for the Syſtem in a Dictionary of Arts and Sciences, eſpecially where unintereſted prolixity is exploded.

Notwithſtanding I am perſuaded the ſtudient will here find the fundamentals of the art ſufficiently treated of, to enable him in a variety of caſes to make the application, and to read with pleaſure thoſe Authors who have written learnedly on the ſubject; and it was under this idea that I have given the names of ſuch as I thought beſt deſerving of his attention.

SECTION I.

DEFINITIONS.

I. As, according to this art, Problems are computed by the means of letters and other characters, ſo it is to be obſerved, that the firſt letters of the Alphabet, as *a*, *b*, *c*, *d*, &c. are uſually put for unknown quantities; and the laſt, as V, X, Y, Z, for quantities unknown, which are always aſſumed as if they were really given or known, and are thus managed in the proceſs according to the rules of art, till at length either the unknown quantities themſelves, or certain powers or roots thereof, are found equal to ſome given quantities; and ſo they become known alſo.

II. The ſign $+$ (*plus*) denotes *addition*. Thus $a+b$, ſignifies *b* added to *a*. This is called a *poſitive* or an *affirmative* ſign; and quantities to be added, are ſtiled *poſitive* or *affirmative* quantities.

III. The ſign — (*minus*) denotes *ſubtraction*. Thus $a-b$, ſignifies *b* ſubtracted from *a*. This is called a *negative* ſign; and quantities to be ſubtracted, are named *negative* quantities.

IV. Like ſigns are either all $+$, or all —: Unlike ſigns are $+$ and —.

V. The ſign of *equality* $=$, is placed between the two quantities, to denote them equal. Thus $a=b$, ſhews that *a* and *b*, are equal to each other.

VI. $\times$, Is the ſign of *multiplication*. So $a\times b$; $b\times c\times d$, denote the product of *a* and *b*, and of *b*, *c*, and *d*, reſpectively:

but the product of ſimple quantities is commonly expreſſed by merely joining or annexing the letters; ſo the products of the above quantities are *ab* and *bcd*. Sometimes the product is denoted by putting a point between each quantity, as $b.\overline{c-d}$ denotes *b* multiplied by *c*—*d*.

VII. ÷, Is the ſign of *diviſion*. Hence $a \div b$, ſignifies *a* divided by *b*; but the ſame is generally written in the manner of a fraction. Thus, $\frac{a}{b}$, and $\frac{a-b}{c+d}$, denote *a* divided by *b*, and *a*—*b* divided by *c*+*d* reſpectively.

VIII. ∽, Is put between two quantities to denote their difference; as $a \backsim b$ ſignifies the difference between *a* and *b*, but without ſhewing which is the greater or leſs quantity.

IX. ⊏ or ⅂, are ſigns of *majority*, and ⊐ or ∠ are ſigns of *minority*. Thus *a*⊐*b*, ſhews that *a* is greater than *b*, and *a*⊐*b* ſhews that *a* is leſs than *b*.

X. √, Is the ſign of *radicality*, and of itſelf denotes the *ſquare root*; the *cube root*, *biquadrate root*, &c. are expreſſed by writing a 3 or 4, &c. over it. Thus $\sqrt{a}$, $\sqrt[3]{a}$, and $\sqrt[4]{a}$, denote the ſquare root, cube root, and biquadrate root *a* reſpectively.

XI. ☊, Is the ſign of *involution*, as ☊ 2 ſignifies involved to the ſquare; ☊ 3, involved to the cube, &c.

XII. ɯ, *evolution*, as ɯ 2, ſignifies the ſquare root, ɯ 3, the cube root, &c.

XIII. The *power of a quantity* is its ſquare, cube, biquadrate, &c. and the figure or letter which is put over a quantity to denote the ſame, is named the *index*, *exponent* or *dimenſion*, of ſuch quantity. Thus a^2, a^3, and a^4, denote the ſquare, cube, and biquadrate of *a* reſpectively; or, which is the ſame, the ſecond, third, and fourth power of *a*; and the figures, 2, 3, and 4, are the indices or exponents, &c. of *a*. Sometimes the power of a quantity is ſhewn by repetitions of the letter. Thus *aa* is the ſame as a^2; and *aaa*, the ſame as a^3, &c.

XIV. *Like quantities* are thoſe that conſiſt of the ſame letters, as *a*, $3a-4a$. Alſo *bb*, $3bb-7bb$; and $2abc, -5abc$, &c.

XV. *Unlike quantities* conſiſt of different letters, or of the ſame letters differently repeated; as *a*, *b*, $2c, -3d$; or as *a*, $2aa$, $-5aaa$.

XVI. *Simple quantities* are thoſe which conſiſt of one term only; as $4b$, $3a^2$, $15dcc$, &c.

XVII. *Compound quantities*, are thoſe which conſiſt of ſeveral terms, as $a+b$, $3a-5c$, $a+2b-3c$, &c.

XVIII. A *line* or *vinculum*, drawn over ſeveral quantities, *a*, *b*, *c*, &c. denote them to be eſteemed a compound quantity, as $\overline{a+b-c}$.

XIX. The *coefficient* of a quantity is the number prefixed to it; as, $5a$, where 5 is the coefficient, and ſignifies that *a* is multiplied by 5.

XX. A *binomial quantity* is one conſiſting of two terms; as $a+b$; a *trinomial*, of three terms, as $a+b+c$; a *quadrimonial*, of four terms, as $a+b+c+d$, &c.

XXI. A *reſidual quantity* is a benomial, where one of the terms is negative.

XXII. A *rational quantity* is that which has no radical ſign.

XXIII. A *ſurd* is a quantity that has not a proper root as the ſquare root of *b*, ($\sqrt{b}$); the cube root of *bb* ($\sqrt[3]{bb}$), &c.

XXIV. An *equation* is the mutual comparing of things equal to one another, the ſign of equality being put between them. A Dependent Equation is that which may be deduced from ſome others. An Independent Equation cannot be produced from the others. A Pure Equation contains but one power of the unknown quantity, as a *ſimple equation*, a *pure quadratic*, a *pure cubic*, &c. An Affected Equation contains ſeveral powers of the unknown quantity, and is denominated according to the higheſt power in it, as an *affected quadratic*, an *affected cubic*, an *affected byquadratic*. Moreover, a Simple Equation contains only the ſimple quantity itſelf. A Quadratic, a quantity of two dimenſions; a Cubic, a quantity of three dimenſions, &c.

Note alſo, that the Roots of Quantities are frequently expreſſed by fractional Exponents, as $a^{\frac{1}{2}}$ denotes the Square Root of *a*; $a^{\frac{1}{3}}$, the Cube Root of *a*; $a^{\frac{1}{4}}$, the Biquadrate Root of *a*, &c. Alſo $a^{\frac{2}{3}}$ denotes the Cube Root of a^2; $a^{\frac{3}{4}}$, the Biquadrate Root of a^3, &c. Likewiſe ∷ is the ſign of disjunct proportion, and ∺ of continued proportion, or geometrical progreſſion.

Theſe explications premiſed, I ſhall lay down the following axioms, and then proceed to Algebraical Operations.

AXIOM 1. If equal quantities be added to equal quantities, the ſums will be equal.

2. If equal quantities be taken from equal quantities, the remainders will be equal.

3. If equal quantities be multiplied by equal quantities, the products will be equal.

4. If equal quantities be divided by equal quantities, the quotients will be equal.

5. The equal Powers or Roots of equal quantities are equal.

6. Quantities ſeverally equal to a third quantity, are equal to one another.

7. The whole is equal to all its parts taken together.

SECTION II.

PRIMARY ALGEBRAICAL OPERATIONS.

ART. I. *To add ſeveral Quantities together.*

RULE. 1. If the quantities are like, and have like ſigns, add together the coefficients, and to the ſum prefix the ſame ſign, ſubjoining the common quantity. 2. If the quantities are like, but have unlike ſigns, take the difference between the ſum of the affirmative coefficients, and the ſum of the negative ones, and thereto prefix the ſign of the greater ſum, annexing alſo the proper quantity. 3. But if the quantities are all unlike with unlike ſigns, write them down one after another, prefixing to each its proper ſign.

EXAMPLES.

$$\begin{array}{lr} & 12ab\\ & 5ab\\ & 7ab\\ \hline \text{Sum} & 24ab. \end{array} \qquad \begin{array}{lr} & 11a^2b+3cd^2\\ & 7a^2b+5cd^2\\ & 10a^2b+7cd^2\\ \hline \text{Sum} & 28a^2b+15cd^2. \end{array} \qquad \begin{array}{lr} & -25x^2y^3-x^4\\ & -37x^2y^3-3x^4\\ & -54x^2y^3-5x^4\\ \hline \text{Sum} & -116x^2y^3-9x^4. \end{array}$$

$$\begin{array}{ll} & -2aa-7bcd+dd\\ & +7aa-20bcd-dd\\ & +3aa+6bcd\\ \hline \text{Sum} & +8aa-21bcd\ *. \end{array} \qquad \begin{array}{ll} & +15a^2-3a+db\\ & -4c^2+ad-5db\\ & +dc-5a+d^2\\ \hline \text{Sum} & +15a^2-4c^2+dc-8a+ad-4db+d^2 \end{array}$$

N. B. Where there is no coefficient prefixed to a quantity, it is underſtood that the coefficient is 1; and where there is no ſign prefixed, the quantity is affirmative.

ART. II. *To ſubtract Algebraical Quantities.*

RULE. Change the ſigns of the quantities to be ſubtracted, and then add the whole together as in addition.

EXAMPLES.

$$\begin{array}{ll} \text{From} & 5a^2b-cd\\ \text{Take} & -3a^2b+2cd\\ \hline \text{Remaind.} & 8a^2b-3cd \end{array} \qquad \begin{array}{ll} \text{From} & 3a^2-2a+cd-d^2-f^2\\ \text{Take} & -2a^2-5a-3ab-2d^2\\ \hline \text{Remaind.} & 6a^2+3a+cd+3ab+d^2-f^2 \end{array}$$

ART. III. *To multiply Algebraical Quantities.*

RULE. Multiply each term of the multiplier into every term of the multiplicand, viz. the coefficients into the coefficients, and the letters into the letters, by placing them together like letters in a word; and prefix + to like ſigns, and — to unlike ſigns. The ſum of all will be the product ſought.

EXAMPLES.

$$\begin{array}{lr} \text{Multiply} & 3a\\ \text{by} & 5b\\ \hline \text{Product} & 8ab \end{array} \qquad \begin{array}{lr} \text{Multiply} & -7a^2\\ \text{by} & -5c^2\\ \hline \text{Product} & +35a^2c^2 \end{array} \qquad \begin{array}{lr} \text{Multiply} & -4cd^2\\ \text{by} & +8a^2\\ \hline \text{Product} & -32cd^2a^2 \end{array}$$

$$\begin{array}{ll} \text{Mult.} & 5a+3b\\ \text{by} & 2a+b\\ \hline & 10aa+6ab\\ & \quad\ +5ab+3bb\\ \hline \text{Prod.} & 10aa+11ab+3bb \end{array} \qquad \begin{array}{ll} \text{Mult.} & 3xx-5ax\\ \text{by} & x+2a\\ \hline & 3xxx-5axx\\ & \qquad\ +6axx-10aax\\ \hline \text{Prod.} & 3xxx+axx-10aax \end{array}$$

$$\begin{array}{ll} \text{Mult.} & a^2+ab-b^2\\ \text{by} & a-b\\ \hline & a^3+a^2b-ab^2\\ & \quad\ -a^2b-ab^2+b^3\\ \hline \text{Prod.} & a^3\ *\ -2ab^2+b^3 \end{array} \qquad \begin{array}{ll} \text{Mult.} & a^2+b^2\\ \text{by} & c^2-d^2\\ \hline & a^2c^2+c^2b^2\\ & -d^2a^2-d^2b^2\\ \hline \text{Prod.} & a^2c^2+b^2c^2-d^2a^2-d^2b^2 \end{array}$$

ART. IV. *To divide one Quantity by another.*

Rule I. In ſimple quantities, which will divide without a remainder, divide the coefficient by the coefficient, and place the anſwer in the quotient, annexing thereto thoſe letters of the dividend which are not found in the diviſor, and obſerving that like ſigns produce +, and unlike ſigns —.

EXAMPLES.

$$\begin{array}{rl} 3ab) & 21abcd\ (7cd\\ & 21abcd\\ \hline & \qquad\quad 0 \end{array} \qquad \begin{array}{rl} -5a^2b) & 25a^3b^3d\ (-5ab^2d\\ & 25a^3b^3d\\ \hline & \qquad\quad 0 \end{array}$$

Rule II. In compound quantities, divide the firſt term of the dividend by the firſt term of the diviſor (the quantities being firſt ranged in due order according to the dimenſions of ſome letter) and place the reſult in the quotient. Multiply the whole diviſor by the quotient, and ſubtract it from the dividend, to which bring down the next term in the dividend, and repeat the operation as in common arithmetic till the work is done.

EXAMPLES.

$$\begin{array}{l} 2b-3c)\,8baa-12caa\,(4aa \\ \qquad\quad \underline{8baa-12caa} \\ \qquad\qquad\quad 0 \end{array} \qquad \begin{array}{l} a+b)\,a^2-b^2\,(a-b \\ \qquad\;\; \underline{a^2+ab} \\ \qquad\quad -ab-b^2 \\ \qquad\quad \underline{-ab-b^2} \\ \qquad\qquad\quad 0 \end{array}$$

$$\begin{array}{l} 3a-b)\,3a^3-12a^2-ba^2+10ab-2b^2\;(a^2-4a+2b \\ \qquad\quad \underline{3a^3 \qquad\quad -ba^2} \\ \qquad\qquad -12a^2 \; * \; +10ab \\ \qquad\qquad \underline{-12a^2 \qquad +4ab} \\ \qquad\qquad\qquad\quad +6ab-2b^2 \\ \qquad\qquad\qquad\quad \underline{+6ab-2b^2} \\ \qquad\qquad\qquad\qquad\quad 0 \end{array}$$

SCHOLIUM. It will often happen that the diviſor will not exactly divide the dividend, in which caſe it will be proper to place the dividend over the diviſor in form of a fraction, throwing out ſuch letters as are found in all the terms of the dividend and diviſor. Thus, if the dividend is $ax+x^2$, and the diviſor $ax-x^2$, the quotient will be $\frac{ax+x^2}{ax-x^2}=\frac{a+x}{a-x}$.

It is alſo obſervable that any power of a quantity is divided by any power of another quantity, by ſubtracting the exponent of the diviſor from the exponent of the dividend.

Thus $\frac{5a^7}{a^3}=5a^{7-3}=a^4$. And $\frac{12b}{9b^3}=\frac{16b^{1-3}}{12b^3}=\frac{16b^{-2}}{12}=\frac{4b^{-2}}{3}$; and this expreſſion is alſo equal to $\frac{4}{3b^2}$, for it is evident from what has been ſaid, that an affirmative power, in the denominator, makes (if transferred) a negative one in the numerator; and of conſequence a negative power in the numerator is transferable to an affirmative one in the denominator.

SECT. III.

OF FRACTIONS.

ART. V. The rules for managing Algebraic Fractions are preciſely the ſame as thoſe for Vulgar Fractions in Arithmetic, and therefore it would be ſuperfluous to preſent them here, as it is preſumed that thoſe who attempt Algebra are at leaſt well verſed in Arithmetical Operations; and if in any inſtance the reader ſhould not perfectly recollect them, he will find ample ſatisfaction by referring to the rules given for fractions in our NEW SYSTEM OF ARITHMETIC. However, that there may not be the leaſt defection in the ſyſtem here advanced, a few Examples follow by way of exerciſes.

EXAMP. I. Let $\frac{a}{b}$ be reduced to a fraction, whoſe denominator is $b-c$. Here $\frac{a}{b}\times\overline{b-c}=a-\frac{ac}{b}$, and $\frac{a-\frac{ac}{b}}{b-c}$ is the fraction required.

EXAMP. II. Let the mixt quantity $a-\frac{b}{c}$ be reduced to a fraction. Here $\frac{ca-b}{c}$ is the fraction required.

EXAMP. III. Let $\frac{bd-b^2}{d}$ be reduced to a mixt quantity. Here, by dividing $bd-b^2$ by d, the quotient will be b, and the remainder will be $-b^2$; and therefore the anſwer will be $b-\frac{b^2}{d}$.

EXAMP. IV. What is the greateſt common diviſor of $\frac{ad+d^2}{b^2a+b^2d}$?

ANSW. $a+d$, and therefore $\frac{d}{b^2}$ is the fraction in its loweſt terms.

EXAMP. V. Reduce $\frac{a}{b}$, $\frac{c}{d}$, and $\frac{e}{f}$, to fractions of the ſame value, having one common denominator.

ANSW. $\frac{adf}{bdf}$, $\frac{cbf}{bdf}$, and $\frac{edb}{bdf}$, are the fractions required: ſo, in like manner, if it were required to add $\frac{a}{b}$, $\frac{c}{d}$, and $\frac{e}{f}$, together their ſum would be $\frac{adf+cbf+edb}{bdf}$.

In the ſame way the ſum of $\frac{\overline{m+n}^{\frac{a}{c}}}{\overline{d+e}^{2}}$ and $\frac{d+e}{\overline{m+n}^{2}}$ will be found

$$=\frac{\overline{m+n}^{\frac{2c+a}{c}}+\overline{d+e}^{3}}{\overline{d+e}^{2}\times\overline{m+n}^{2}}.$$

Alſo $\frac{a+b}{d}-\frac{b^2}{a}=\frac{a^2+ab-db^2}{ad}$.

And $\frac{m}{a^2+b^c}-\frac{a^2+b^c}{m^2}=\frac{m^3-a^2\,\overline{+b^c}}{m^2a^2+m^2b^c}$.

Again, $\frac{5x^2}{y^3}$, multiplied by $\frac{4y^5}{3x^4}=\frac{5x^2\times4y^5}{3x^4\times y^3}=\frac{20x^2y^5}{3x^4y^3}=\frac{20y^2}{3x^2}$ the product.

And $\frac{\overline{a-b}^{2}}{cd}$ divided by $\frac{d^3}{\overline{a-b}^{n}}=\frac{\overline{a-b}^{n+2}}{cd^4}$. The operations of any other Fractions are equally eaſy.

ART. VI. INVOLUTION.

To find the Square, Cube, Biquadrate, &c. of any given Quantity.

RULE. Multiply the quantity into itſelf as often as the index contains units, leſs one, and the laſt product will be the power required; or which is equivalent thereto, and in many caſes is more convenient, multiply the index of the quantity by the index of the power, and you will have the anſwer, due regard being had to the ſigns.

EXAMPLES.

$$\begin{array}{l}\text{If } a\\ \text{be the}\\ \text{Root,}\\ \text{then}\end{array}\left\{\begin{array}{l}a^2=\text{Square}\\ a^3=\text{Cube}\\ a^4=\text{Biquadrate}\\ a^5=\text{5th Power}\end{array}\right\}\left\{\begin{array}{l}\text{If}\\ -2a^2b^2\\ \text{be the}\\ \text{root, then}\end{array}\right.\left\{\begin{array}{ll}+\;4a^4b^4 & =\text{Square}\\ -\;8a^6b^6 & =\text{Cube}\\ +16a^8b^8 & =\text{4thPowr}\\ -32a^{10}b^{10} & =\text{5thPowr}\end{array}\right.$$

$$\begin{array}{l} b+c\text{ Root} \\ \underline{b+c} \\ b^2+bc \\ \underline{\quad\;\, +bc+c^2} \\ b^2+2bc+c^2=\text{Square} \\ \underline{b+c} \\ b^3+2b^2c+bc^2 \\ \underline{\qquad b^2c+2bc^2+c^3} \\ b^3+3b^2c+3bc^2+c^3=\text{Cube} \end{array} \qquad \begin{array}{l} b-c\text{ Root} \\ \underline{b-c} \\ b^2-bc \\ \underline{\quad\;\, -bc+c^2} \\ b^2-2bc+c^2\text{ Square} \\ \underline{b\;+c} \\ b^3-2b^2c+bc^2 \\ \underline{\qquad -b^2c+2bc^2-c^3} \\ b^3-3b^2c+3bc^2-c^3\text{Cube} \end{array}$$

It is obſervable that, in raiſing a Binomial, where one of the quantities is negative, as in the inſtance above $(b-c)$ the terms in every power are + and — alternately. The operation, indeed, is only continued to the 3d Power, but the obſervation is univerſal, and even a young beginner in the art, by continuing the Multiplication, will eaſily raiſe the quantity to any higher power.

In raiſing trinomials, quadrinomials, &c. it will render the work leſs tedious to divide the root into two parts, taking but one term into one of the parts, and aſſuming ſome other letter in lieu of the reſt; by which means the quantity will be reduced to a binomial, which being raiſed to the required power, the anſwer will be obtained by replacing, inſtead of the aſſumed letter, its proper value.

Thus if $b+c+d$ is to be raiſed to the third power, aſſume $b+c=a$, and ſo the trinomial $b+c+d$ is changed into the binomial $a+d$. Then $\overline{a+d}^{3}=a^3+3a^2d+3ad^2+d^3=\overline{b+c}^{3}+3d\times\overline{b+c}^{2}+3d^2\times\overline{b+c}+d^3$. But $\overline{b+c}^{3}=\underline{b^3+3b^2c+3bc^2+c^3}$; and $3d\times\overline{b+c}^{2}=3d\times\overline{b^2+2bc+c^2}=3db^2+6dbc+3dc^2$, alſo $3d^2\times\overline{b+c}=3d^2b+3d^2c$. Therefore $\overline{b+c}^{3}+3d\times\overline{b+c}^{2}+3d^2\times\overline{b+c}+d^3=b^3+3b^2c+3bc^2+c^3+3db^2+6dbc+3dc^2+3d^2b+3d^2c+d^3=$ the cube of $b+c+d$, which was to be effected.

In fractional quantities, the numerator and denominator muſt each be involved to the required power, by which a new fraction will be obtained exhibiting that power of the fraction given.

Thus the 3d Power of $\frac{a^2}{b^3}=\frac{a^6}{b^3}$; the Square of $\frac{a+b}{d+c}=\frac{a^2+2ab+b^2}{d^2+2dc+c^2}$; the 5th Power $\frac{a^m c^n}{b^2 d^r}=\frac{a^{5m}c^{5n}}{b^{10}d^{5r}}$; and the n^{th} Power of $\frac{x^{n+1}}{a+b}=\frac{x^{nn+n}}{\overline{a+b}^{n}}$.

What has been delivered on this head is ſufficient for ſhewing how to involve Algebraic quantities to any power, whether they are ſimple, compound, or fractional. I cannot, however, cloſe the article without introducing the BINOMIAL THEOREM, which, for theſe purpoſes, of all methods is the moſt uſeful, conciſe, and elegant, and will be a laſting ornament to the name of its renowned inventor, the incomparable Sir ISAAC NEWTON. The Theorem is as follows: Let n denote any number at pleaſure, and let $a+b$ be a binomial, then the n^{th} Power thereof will be

$$a^{n}+na^{n-1}b+\frac{n.\overline{n-1}}{2}.a^{n-2}b^{2}+\frac{n.\overline{n-1}.\overline{n-2}}{2.3}a^{n-3}b^{3}+\frac{n.\overline{n-1}.\overline{n-2}.\overline{n-3}}{2.3.4.}a^{n-4}b^{4}+\frac{n.\overline{n-1}.\overline{n-2}.\overline{n-3}.\overline{n-4}.}{2.3.4.5}a^{n-5}b^{5}+\frac{n.\overline{n-1}.\overline{n-2}.\overline{n-3}.\overline{n-4}.\overline{n-5}}{2.3.4.5.6}a^{n-6}b^{6},$$

&c. the law of continuation being manifeſt. And the n^{th} power of $a-b$ will be expreſſed in the ſame manner, only the ſigns of the 2d, 4th, 6th, &c. terms muſt be negative. The uſe of this Theorem will be evident from the following Example.

Let $a+b$ be involved to the 3d power. Here the Index is 3, which muſt be placed inſtead of n in the Theorem, and the firſt term will be a^{3}; the ſecond $3a^{3-1}b=3a^{2}b$; the third $\frac{3\times2}{2}a^{3-2}b^{2}=3ab^{2}$; the fourth, $\frac{3\times2\times1}{2\times3}a^{3-3}b^{3}=b^{3}$; and the fifth and following terms will be found equal to nothing. Therefore, collecting theſe four terms together, the third power of $a+b$ is $a^{3}+3a^{2}b+3ab^{2}+b^{3}$.

N. B. The coefficients increaſe till the indices of the two letters a and b become equal or change values, when they return or decreaſe again, after the ſame order, ſo that having found the coefficients of half the terms, the reſt become known alſo.

ART. VII. EVOLUTION.

To find the Roots of given Powers.

RULE I. In ſimple quantities extract the root of the coefficient for a new coefficient, and divide the index of the letters by the index of the power, and you will have the root ſought.

Thus, the Square Root of $16x^{2}=4x^{\frac{2}{2}}=4x$; the Cube Root of $27x^{3}=3x^{\frac{3}{3}}=3x$; the Square Root of $5a^{\frac{2}{2}}x^{\frac{6}{2}}=a^{\frac{2}{2}}x^{\frac{2}{6}}\sqrt{5}=ax^{3}\sqrt{5}$; the Biquadrate Root $81a^{4}x^{8}=3a^{\frac{4}{4}}x^{\frac{8}{4}}=3ax^{2}$; and ſo for any others.

RULE II. To find the Root of Compound Quantities, range the terms after the dimenſions of ſome letter, ſo that the higheſt power thereof may ſtand firſt in order, and the reſt follow according to their ſeveral ranks; then take the root of the firſt term, and place it in the quotient; and, if it be the Square or Cube Root, ſubtract the ſquare or cube thereof from the firſt term, bringing down two or three of the next terms (accordingly as the caſe ſhall be the ſquare or cube root) for a dividend; then proceed to find a diviſor, and in all reſpects to carry on the work agreeable to the rules given for extracting the Square and Cube Roots in our New Syſtem of ARITHMETIC. But if it be the Root of a higher Power that is wanted proceed according to the GENERAL RULE for extracting the roots of all powers, as delivered in our ſaid New Syſtem.

EXAMPLES.

Let the Square Root of $36x^{4}+108x^{2}+81$ be required.

Operation.

$$\begin{array}{rl} & 36x^{4}+108x^{2}+81\ (\overset{\text{Root}}{6x^{2}+9} \\ & \underline{36x^{4}} \\ 12x^{2}+9) & +108x^{2}+81 \\ & \underline{+108x^{2}+81} \end{array}$$

What is the Cube Root of $x^{3}-6x^{2}y+12xy^{2}-8y^{3}$?

$$\begin{array}{rl} & x^{3}-6x^{2}y+12xy^{2}-8y^{3}\ (\overset{\text{Root}}{x-2y} \\ & \underline{x^{3}} \\ 3x^{2}-6xy+4y^{2}) & -6x^{2}y+12ay^{2}-8y^{3} \\ & \underline{-6a^{2}y+12xy^{2}-8y^{3}} \end{array}$$

What is the Square Root of $x^{2}+4xy+4y^{2}-2xz-4yz+z^{2}$?

$$\begin{array}{rl} & x^{2}+4xy+4y^{2}-2xz-4yz+z^{2}\ (\overset{\text{Root}}{x+2y-z} \\ & \underline{x^{2}} \\ 2x+2y & 4xy+4y^{2} \\ & \underline{4xy+4y^{2}} \\ 2x+4y-z) & -2xz-4yz+z^{2} \\ & -2xz-4yz+z^{2} \end{array}$$

Note, here three terms are brought down, which, at firſt ſight appears rather contrary to the Rule; but the reaſon is, the two terms $-2xz$ and $-4yz$, are conſidered but as one term, becauſe z in the *ſame power* is found in both of them, and they might have been expreſſed in one term. Thus $-2xz-4yz=-\overline{2x-4y}\times z$; ſo that $-\overline{2x-4y}$ may be conſidered as a coefficient to z.

What is the 4th Root of $16a^{4}-96a^{3}b+216a^{2}b^{2}-216ab^{3}+81b^{4}$?

$$\begin{array}{rl} & 16a^{4}-96a^{3}b+216a^{2}b^{2}-216ab^{3}+81b^{4}\ (\overset{\text{Root}}{2a-3b.} \\ & \underline{16a^{4}} \\ 32a^{3}) & -96a^{3}b\ (-3b \\ & \underline{-96a^{3}b} \\ & \underline{16a^{4}-96a^{3}b+216a^{2}b^{2}-216ab^{3}+81b^{4}} \end{array}$$

SCHOLIUM. The Root may ſometimes be diſcovered by extracting the Roots of all the Simple Powers, or terms in the given quantity, and connecting the Roots by the ſigns + and —, according as it ſhall appear to agree with the caſe. Thus in the laſt Example the 4th Root of $16a^{4}$ is $2a$, and of $81b^{4}$ is $3b$, and by connecting them with the ſign —, viz. $2a-3b$, you have the Root required.

It is alſo obſervable, that the even Root of any affirmative quantity, as the 2d, 4th, 6th, &c. may be either + or —, and the odd root of any quantity, as the 3d, 5th, 7th, &c. will have the ſame ſign as the quantity itſelf. The even Root of a negative quantity is impoſſible, for if it had a Root, its ſign muſt be either + or —; but all the even powers of any Root, whether affirmative or negative, are affirmative, and therefore no Root involved an even number of times can produce a negative Power, and of conſequence a negative Power can have no Root.

If a fractional quantity is to be evolved, the Roots of the numerator and denominator make the numerator and denominator of the Root of ſuch fraction. Thus the Square Root of $\frac{4a^{2}}{36b^{4}}=\frac{\sqrt{4a^{2}}}{\sqrt{36b^{4}}}=\frac{2a}{6b^{2}}$, and the Cube Root of $\frac{27a^{6}}{64x^{3}}=\frac{\sqrt[3]{27a^{6}}}{\sqrt[3]{64x^{3}}}=\frac{3a^{2}}{4x}$.

It frequently happens that the quantity given to be extracted has not a perfect Root, and then the Root is called a Surd; and in that caſe it can be no otherways expreſſed than by either inſerting the quantity with its proper radical ſign, or throwing it into an infinite Series. Thus the Square Root of a can be expreſſed no otherways than by $\sqrt{a}$, or $a^{\frac{1}{2}}$; the Cube Root of $b^{2}=\sqrt[3]{b^{2}}$ or $b^{\frac{2}{3}}$; the Cube Root of $\frac{a^{2}b}{c^{2}}=\sqrt[3]{\frac{a^{2}b}{c^{2}}}=\overline{\frac{a^{2}b}{c^{2}}}\Big|^{\frac{1}{3}}=\frac{a^{\frac{2}{3}}b^{\frac{1}{3}}}{c^{\frac{2}{3}}}$ and the Square Root of $a^{2}+x^{2}=\sqrt{a^{2}+x^{2}}=$ (by the common Rule of Extraction) $a+\frac{x^{2}}{2a}-\frac{x^{4}}{8a^{3}}+\frac{x^{6}}{16a^{5}}-\frac{5x^{8}}{128a^{7}}$, &c. The ſeveral ways of managing Surds will be particularly handled in the next article.

SECT. IV.

SURD QUANTITIES.

I HAVE ſaid before, that a Surd is the Root of ſuch a quantity as cannot be perfectly extracted; however, it will ſometimes happen in algebraic operations, that a Root cannot be exhibited in rational quantities, which nevertheleſs is not a Surd in itſelf, but may be perfectly expreſſed in numbers, by ſubſtituting, inſtead of the literal characters, their proper value.

Thus $\sqrt{a^{2}+x^{2}}$ cannot be perfectly extracted in algebraic terms; but if the value of a be 3, and the value of x be 4, then $a^{2}=9$, and $x^{2}=16$, and the Surd becomes $\sqrt{9+16}=\sqrt{25}=5$; a rational number. Whence a Surd, ſtrictly ſpeaking, is ſuch a quantity as is not commenſurable by the ſcale of rational numbers.

Again, Surds, though incommenſurable with rational quantities, may, notwithſtandſtanding, be commenſurate among themſelves.

Thus $\sqrt{2}$, $3\sqrt{2}$, and $5\sqrt{2}$, are each incommenſurate to any rational number; but, with regard to themſelves, they are in the perfect ratio of their coefficients 1, 3, and 5, reſpectively. This being premiſed, I ſhall proceed to the Algorithm of Surd Quantities.

ART. VIII. *To reduce a rational quantity to the form of a Surd.*

RULE. Multiply the index of the quantity, by the index of the Surd, and over the quantity ſo produced, place the radical ſign, and it will be the form required.

Thus, let 3, be reduced to the form of $\sqrt{5}$. By the Rule $3^{1\times2}$, or $3^{2}=9$, and $\sqrt{9}$ is the form required.

Again, let a^{2} be reduced to the form of $\sqrt{b}$. Here $a^{2\times3}=a^{6}$, and $\sqrt{a^{6}}$ is the required form.

In like manner, $a+b$ reduced to the form of $\sqrt{cd}$, is $\sqrt{\overline{a+b}^{2}}$, or $\sqrt{a^{2}+2ab+b^{2}}$; and $\frac{a}{b\sqrt{d}}$ reduced to the form of $\sqrt{c}$, is $\sqrt{\frac{a^{2}}{b^{2}d}}$.

ART. IX. *To reduce Quantities of different Indices to other equivalent ones, which ſhall have one given Index.*

RULE. Divide the indices of the quantities by the given Index, and the quotients will be the new indices for thoſe quantities. Then over the ſaid quantities with their new indices, place the given Index, and they will be the equivalent values required.

EXAMP. Let $12^{\frac{1}{2}}$ and $9^{\frac{1}{4}}$ be reduced to equivalent quantities having the common Index $\frac{1}{3}$. Here $\frac{1}{2}\div\frac{1}{3}=\frac{3}{2}=$ the Index of the firſt quantity; and $\frac{1}{4}\div\frac{1}{3}=\frac{3}{4},=$ the Index of the ſecond quantity; therefore $\left.\overline{12^{\frac{3}{2}}}\right|^{\frac{1}{3}}$ and $\left.\overline{9^{\frac{3}{4}}}\right|^{\frac{1}{3}}$ are the quantities required.

Alſo, if $a^{\frac{1}{3}}$ and $b^{\frac{1}{4}}$ are to be reduced to the common index, $\frac{1}{5}$ they will be found $=\left.\overline{a^{\frac{5}{3}}}\right|^{\frac{1}{5}}$, and $\left.\overline{b^{\frac{5}{4}}}\right|^{\frac{1}{5}}$ reſpectively; and ſo for any others.

ART. X. *To reduce quantities of different Indices to other equivalent ones, having the leaſt common Index.*

RULE. Reduce the Indices of the given quantities to a common denominator, in the leaſt terms.

EXAMP. Reduce $a^{\frac{1}{n}}$ and $b^{\frac{1}{m}}$ to the leaſt common Index.

Here $\frac{1}{n}$ and $\frac{1}{m}$ reduced to a common denominator are $\frac{m}{nm}$ and $\frac{n}{nm}$; and therefore $a^{\frac{m}{nm}}$ and $b^{\frac{n}{nm}}$ are the expreſſions required, or which are the ſame, $\sqrt[nm]{a^m}$, and $\sqrt[nm]{b^n}$.

Alſo, $\sqrt{a+b}$, and $\sqrt[3]{x^2+y^2}$ will in like manner be found $\left.\overline{a+b}\right|^{\frac{3}{6}}$ and $\left.\overline{x^2+y^2}\right|^{\frac{2}{6}}$, or $\sqrt[6]{\left.\overline{a+b}\right|^{3}}$ and $\sqrt[6]{\left.\overline{x^2+y^2}\right|^{2}}$, or $\left.\overline{3a^3+3a^2b+3ab^2+b^3}\right|^{\frac{1}{6}}$ and $\left.\overline{x^4+2x^2y^2+y^4}\right|^{\frac{1}{6}}$.

ART. XI. *To reduce a Surd to its moſt ſimple Terms.*

RULE. Divide by the greateſt power contained in it, and place the root before the quotient, with the radical ſign between them.

Thus let $\sqrt{32}$ be reduced to its moſt ſimple terms. Here 16 is the greater ſquare number that will divide 32; the diviſion being made the quotient is 2; therefore $4\sqrt{2}$ is the Surd required.

Let $\left.\overline{81a^2b}\right|^{\frac{1}{2}}$ be propoſed. Here $81a^2$ is the greateſt ſquare; its root is $9a$; and the quotient is b. Therefore $9a\sqrt{b}$ is the Surd in its moſt ſimple terms.

Again, let $\left.\frac{64a^4b^3}{27b-27a}\right|^{\frac{1}{3}}$ be given. This is $=\left.\frac{64a^3b^3\times a}{27b-27a}\right|^{\frac{1}{3}}$ $=\frac{4ab}{3}\sqrt[3]{\frac{a}{b-a}}$; and thus for any other.

ART. XII. *To find whether Surds are commenſurable or not.*

RULE. Reduce them to the leaſt common index; and the quantities, if fractional, to a common denominator, except where like terms are commenſurable. Then divide them by the greateſt common diviſor, (or by ſuch a one as will give one quotient rational) and if both the quotients are rational, the Surds are commenſurable; but if otherwiſe, they are incommenſurable.

EXAMP. Let $\sqrt{27}$ and $\sqrt{12}$ be propoſed. Theſe have already one common index, and are equal to $\sqrt{3\times9}$ and $\sqrt{3\times4}$ reſpectively. Divide by 3, and the quotients are $\sqrt{9}$ and $\sqrt{4}$, that is, 3 and 2; and therefore they are commenſurable.

Again, let $\sqrt{48}$ and $\sqrt{6}$ be propoſed. Here by dividing by 6 the quotients are $\sqrt{8}$, and $\sqrt{1}$ or 1, and therefore they are incommenſurable.

Alſo if $\left.\frac{b}{c}\right|^{\frac{1}{2}}$ and $\left.\frac{c}{b}\right|^{\frac{3}{4}}$ be propoſed, theſe are reduced to $\left.\frac{b^2}{c^2}\right|^{\frac{1}{4}}$, and $\left.\frac{c^3}{b^3}\right|^{\frac{1}{4}}$, and theſe again to $\left.\frac{b^5}{c^2b^3}\right|^{\frac{1}{4}}$ and $\left.\frac{c^5}{c^2b^3}\right|^{\frac{1}{4}}$. Divide by $\frac{1}{c^2b^3}$, and the quotients are $\left.\overline{b^5}\right|^{\frac{1}{4}}$ and $\left.\overline{c^5}\right|^{\frac{1}{4}}$. Wherefore they are incommenſurable. Furthermore, if $\left.\overline{x^4+x^2y^2}\right|^{\frac{1}{2}}$ and $\left.\overline{x^2y^2+y^4}\right|^{\frac{1}{2}}$ be propoſed. Divide theſe quantities by x^2+y^2 and the quotients are $\sqrt{x^2}$ and $\sqrt{y^2}$, or x and y. Hence the quantities are commenſurable. Theſe inſtances are ſufficient to point out the method of performing all other ſimilar caſes.

ART. XIII. *To add and ſubtract Surd quantities.*

RULE. Reduce quantities with unlike indices to thoſe of like indices; and bring fractions to a common denominator, or elſe to others that have rational denominators or numerators; then reduce the quantities to their ſimpleſt terms (by Art. XI.); and if the Surd part be the ſame in all, annex it to the SUM or DIFFERENCE with the ſign (×) of Multiplication.

If the Surd part is not the ſame in all, the quantities can only be added or ſubtracted by connecting them together with the ſigns + or —.

EXAMP. Let $\sqrt{18}$ and $\sqrt{50}$ be added together. Here $\sqrt{18}=\sqrt{9\times2}=3\sqrt{2}$; and $\sqrt{50}=\sqrt{25\times2}=5\sqrt{2}$, and the ſum $=\overline{3+5}\times\sqrt{2}=8\sqrt{2}=\sqrt{128}$.

Let $\sqrt{4a}$ and $\sqrt[4]{a^6}$ be added. Here $\sqrt{4a}=\sqrt[4]{16a^2}=2\sqrt[4]{a^2}$. And $\sqrt[4]{a^6}=\sqrt[4]{a^4\times a^2}=a\sqrt{a^2}$. Therefore their ſum $=\overline{a+2}\times\sqrt[4]{a^2}=\overline{a+2}\times\sqrt{a}$. In like manner, if it had been required to have ſubtracted $\sqrt{4a}$ from $\sqrt[4]{a^6}$, the remainder would have been $\overline{a-2}\times\sqrt{a}$. — Alſo if $\sqrt[3]{a^2}-\sqrt{a^3}+\sqrt{7}$ is added to $2\sqrt[3]{a^2}+\sqrt{a}-\sqrt{3}$. The ſum is $3\sqrt[3]{a^2}-\sqrt{a^3}+\sqrt{7}+\sqrt{a}-\sqrt{3}$; but, if ſubtracted therefrom the remainder $\sqrt[3]{a^2}+\sqrt{a}-\sqrt{3}+\sqrt{a^3}-\sqrt{7}$.

If $\sqrt{\frac{2}{3}}$ is added to $\sqrt{\frac{24}{25}}$ the ſum is $\sqrt{\frac{50}{75}}+\sqrt{\frac{72}{75}}=\sqrt{\frac{2\times25}{75}}+\sqrt{\frac{2\times36}{75}}=5\sqrt{\frac{2}{75}}+6\sqrt{\frac{2}{75}}=\overline{5+6}\times\sqrt{\frac{2}{75}}=11\sqrt{\frac{2}{75}}$; but if ſubtracted the remainder is $\overline{6-5}\times\sqrt{\frac{2}{75}}=\sqrt{\frac{2}{75}}$. The procedure is the ſame for any other quantities.

ART. XIV. *To multiply and divide Surds.*

RULE. Reduce the Surds to the ſame index; and the product or quotient of the rational quantities being annexed to the product or quotient of the Surds, will give the product or quotient required.

EXAMP. Let $2\sqrt{2}$ be multiplied by $3\sqrt{3}$. Here the Surds have already the ſame index. Therefore $2\times3\times\sqrt{2\times3}=6\sqrt{6}$ is the Product required. Let $a^{\frac{1}{3}}$ be multiplied by $b^{\frac{1}{4}}$. Here $a^{\frac{1}{3}}=\left.\overline{a^4}\right|^{\frac{1}{12}}$, and $b^{\frac{1}{4}}=\left.\overline{b^3}\right|^{\frac{1}{12}}$; and their product is $\left.\overline{a^4b^3}\right|^{\frac{1}{12}}$. Let $x^{\frac{1}{2}}+2y^{\frac{1}{3}}$ be multiplied by $5yx^{\frac{1}{2}}$. Here $x^{\frac{1}{2}}$ (the firſt term) $\times5yx^{\frac{1}{2}}=\overline{1\times5y}\times\sqrt{xx}=5yx$; alſo the ſecond term $+2y^{\frac{1}{3}}=2\sqrt[6]{y^2}$, and $5yx^{\frac{1}{2}}=5\sqrt[6]{y^6x^3}$, and their product $=+\overline{2\times5}\times\sqrt[6]{y^2\times y^6x^3}=+10\sqrt[6]{y^8x^3}$, and therefore the whole product is $5ya+10\sqrt[6]{y^8x^3}$. If both Quantities are compound, the operation will be equally eaſy, due regard being paid as well to the inſtructions in ART. III. as to the Rule here given.

Let $a-a\sqrt{x}$ be multiplied by $b-b\sqrt{x}$. Here the product by b is $ab-ab\sqrt{x}$; and the product by $-b\sqrt{x}=-ab\sqrt{x}+abx$, and their ſum is $ab-2ab\sqrt{x}+abx$, the anſwer ſought.

So in diviſion, if $z^{\frac{1}{2}}$ be divided by $y^{\frac{1}{3}}$, the quotient will be $\left.\frac{z^3}{y^2}\right|^{\frac{1}{6}}$; alſo $\frac{3x^{\frac{1}{n}}y^{\frac{1}{m}}}{4a}$ divided by $\frac{2y^2x^{\frac{1}{3}}}{5b}=\frac{5b\times3\sqrt[mn]{x^my^n}}{4a\times2\sqrt[3]{y^6x}}=\frac{15b}{8a}\sqrt[3mn]{\frac{x^{3m}y^{3n}}{y^{6mn}x^{mn}}}$; and the like for any other; obſerving in compound quantities to divide each term in the dividend by the whole diviſor, and connect the quotients with the ſigns + or —, as the caſe ſhall be, and further, that the dividing of each ſeparate term by the compound diviſor, is the ſame as multiplying it by the reciprocal thereof.

Thus, if any ſingle term, as $x^{\frac{1}{2}}$ is divided by a compound term, as $x^{\frac{1}{3}}+y^{\frac{1}{2}}$, it is the ſame thing as if it was multiplied by $\frac{1}{x^{\frac{1}{3}}+y^{\frac{1}{2}}}$, and therefore the quotient is $\left.\frac{x^3}{x^2+y^3}\right|^{\frac{1}{6}}$.

N. B. A fraction is changed into its reciprocal, by making the numerator, the denominator; and the denominator, the numerator.

SCHOLIUM. With regard, however, to compound Surds, it will not often happen that any advantage can be derived by the above mode of proceeding. Wherefore it will be proper to try to carry on the diviſion in the ſame form as was ſhewn for compound rational quantities, which ſometimes may be done with great facility. When this fails, the quotient can only be expreſſed by writing the diviſor under the dividend in manner of a fraction.

Art. XIV. *Involution and Evolution of Surd Quantities,*

Are performed by multiplying (if it is a ſimple Surd) the Index of the Quantity, by the Index of the Power to which it is to be involved, or by the fraction expreſſing the Root to which it is to be evolved, and where there is a rational part, its proper Power or Root muſt be prefixed thereto. Thus, the Square of $a\surd x = a^2 \times x^{\frac{1}{2}\times 2} = a^2 \times x^{\frac{2}{2}} = a^2 \times x^1 = a^2 x$. The Cube of $a \surd x^{\frac{5}{2}} = a^3 \times x^{\frac{5}{2}\times 3} = a^3 \times x^{\frac{15}{2}} = a^3 x^{\frac{15}{2}}$, or $a^3 \surd x^{15}$.

Alſo the Cube Root of $\overline{a+x}^{\frac{1}{2}} = \overline{a+x}^{\frac{1}{2}\times\frac{1}{3}} = \overline{a+x}^{\frac{1}{6}}$; and the Biquadrate Root of $81 x^{\frac{2}{3}} = 3 x^{\frac{2}{3}\times\frac{1}{4}} = 3x^{\frac{2}{12}} = 3x^{\frac{1}{6}}$, or $3 \sqrt[6]{x}$.

Scholium. Here no difference is made between Roots and Powers, ſave that the Indices of Powers are whole numbers, but thoſe of Roots, Fractions.

Hence, in many caſes, both Involution and Evolution may be performed at one operation. For inſtance, if it is required to involve $\overline{a+x}^{\frac{1}{4}}$ to the 5th Power; and then to extract the Cube Root thereof, it will be done at once, by multiplying the exponent $\frac{1}{4}$ by $\frac{5}{3}$; and ſo the anſwer is $\overline{a+x}^{\frac{5}{12}}$.

Therefore the Indices of Powers and Roots, thus entangled, may with propriety be deemed fractional powers; and hence in general, $x^{\frac{v}{r}}$ raiſed to the $\frac{n^{\text{th}}}{m}$ power, is $x^{\frac{v}{r}\times\frac{n}{m}} = x^{\frac{vn}{rm}}$.

Compound Surds are involved and extracted as integers or rational quantities, due regard being had to the operations of Simple Surds.

In caſes of Evolution, where the Root of Compound Surds cannot be found, it muſt be denoted by a line or vinculum drawn over the whole, together with the proper radical ſign or index.

Operations of theſe kinds may be much facilitated, by aſſuming, inſtead of Surds, ſome rational quantities or letters, to repreſent them; and by having recourſe to the Binomial Theorem, given in Article the VIth, where n may be taken to denote any power either whole or fractional, and ſo it may be made applicable to caſes of Evolution as well as of Involution; and having by this means obtained the terms of the required power, (which, if fractional, will commonly be an infinite ſeries) the Surds may be reſtored in lieu of the aſſumed letters, obſerving to raiſe the indices of the Surds in each term to the Power, denoted by the indices of their ſubſtitutes.

It was obſerved in the 6th Article, that when the quantity to be involved is a reſidual, viz. when one of the terms are negative, as $a-b$, the terms of any power thereof will be + and — alternately; and in Binomials, where both the terms are negative, that all the terms of whatever power will be affirmative: this however is to be underſtood within this limit, namely, when the power of the quantity to be involved is affirmative.

When the power is negative, as $\overline{a+b}|^{-n}$, or $\overline{a-b}|^{-n}$, in the firſt caſe, all the terms in the odd places will be affirmative, and thoſe in the even places negative; but in the latter caſe all the terms will be affirmative.

N. B. A quantity with a negative power is equal to its reciprocal with an affirmative power. Thus $\overline{a\pm b}|^{-n} = \frac{1}{\overline{a\pm b}|^{n}}$.

This follows from what was obſerved in the Scholium of the 4th Article.

There are other methods of extracting Surd Quantities, though I believe the caſes, to which they may be applied, will not frequently occur into practice; but that nothing may be wanting to render the rudiments of this Syſtem as complete as poſſible, I ſhall lay down another rule which I have ſometimes had recourſe to and found uſeful.

It is this, if $B \pm C$ be a binomial or reſidual Surd, then

$$\sqrt{B\pm C} = \sqrt{\frac{B+\sqrt{B^2-C^2}}{2}} \pm \sqrt{\frac{B-\sqrt{B^2-C^2}}{2}}.$$

The uſe whereof is this: Let $3+\surd 5$, be a binomial, whoſe ſquare root is required. Here the firſt term $B=3$; and $C=\surd 5$. Then $\sqrt{B^2-C^2} = \sqrt{9-5} = \surd 4 = 2$ and $\sqrt{\frac{B+\sqrt{B^2-C^2}}{2}} = \sqrt{\frac{3+2}{2}} = \surd\frac{5}{2} = \surd\frac{10}{4} = 2\surd 10$.

Likewiſe $\sqrt{\frac{B-\sqrt{B^2-C^2}}{2}} = \sqrt{\frac{3-2}{2}} = \surd\frac{1}{2} = \surd\frac{2}{4} = 2\surd 2$. The required Root is $2\surd 10 + 2\surd 2$. If the given quantity had been $3-\surd 5$, the anſwer would have been $2\surd 10 - 2\surd 2$.

N. B. In this Rule B, muſt always be the greater quantity.

Art. XV. *To find the Value of a Fraction in an infinite Series.*

Divide the numerator by the denominator, as in common Diviſion, and continue the operation as far as ſhall be thought neceſſary. In many caſes, after a few terms are had in the quotient, the law by which it converges will be diſcovered, and ſo any number of terms may be ſupplied at pleaſure.

Examples.

Let $\frac{1}{1+x^2}$ be thrown into an infinite ſeries.

$$\begin{array}{l}
1+x^2)\ 1\ (1 - x^2 + x^4 - x^6 + x^8 - \text{\&c.} \\
\quad \underline{1+x} \\
\quad -x^2 \\
\quad \underline{-x^2-x^4} \\
\qquad +x^4 \\
\qquad \underline{+x^4+x^6} \\
\qquad\quad -x^6 \\
\qquad\quad \underline{-x^6-x^8} \\
\qquad\qquad +x^8 \\
\qquad\qquad \underline{+x^8+x^{10}} \\
\qquad\qquad\quad -x^{10}
\end{array}$$

Let $\frac{ax}{a-x}$ be expreſſed by an infinite ſeries.

$$\begin{array}{l}
a-x)\ ax\ \left(x + \frac{x^2}{a} + \frac{x^3}{a^2} + \frac{x^4}{a^3}\ \text{\&c.}\right. \\
\quad \underline{ax-x^2} \\
\quad +x^2 \\
\quad \underline{+x^2-\frac{x^3}{a}} \\
\qquad +\frac{x^3}{a} \\
\qquad \underline{+\frac{x^3}{a}-\frac{x^4}{a^2}} \\
\qquad\quad +\frac{x^4}{a^2} \\
\qquad\quad \underline{+\frac{x^4}{a}-\frac{x^5}{a^3}} \\
\qquad\qquad +\frac{x^5}{a^3}
\end{array}$$

In both of theſe ſeries after a few terms are found, the law of continuation is manifeſt.

Scholium. It will however ſometimes be difficult to come at the ſeries by this mode, by reaſon of the coefficients; and then it will be convenient to aſſume a ſeries with unknown coefficients to repreſent it; which being multiplied or involved, as the queſtion requires, and the quantities of the ſame dimenſion being put equal to each other, Equations will be had, from which the coefficients may be eaſily determined. But this will be better underſtood after we have treated of Equations; wherefore, though I ſhall give an inſtance of it here, the reader will do well to paſs it over, till he knows perfectly how to manage Equations.

The method is this: Suppoſe $\frac{1}{a-x}$ be the given quantity; let the aſſumed ſeries be $A + Bx + Cx^2 + Dx^3 + Ex^4$, &c. $= \frac{1}{a-x}$. Multiply both by $a-x$, and there will be $1 =$

$$\begin{array}{l}
aA + aBx + aCx^2 + aDx^3 + aEx^4,\ \text{\&c.} \\
\quad -\ Ax -\ Bx^2 -\ Cx^3 -\ Dx^4,\ \text{\&c.}
\end{array}$$

and by equating the coefficients of the ſame powers of x, $aA = 1$, $aB - A = o$, $aC - B = o$, $aD - c = o$, $aE - D = o$, &c. Hence in the firſt equation $A = \frac{1}{a}$; in the 2d, $B = \frac{A}{a}, = \frac{1}{a^2}$; in the 3d, $C = \frac{B}{a} = \frac{1}{a^3}$; in the 4th, $D = \frac{C}{a} = \frac{1}{a^4}$; and in like manner $E = \frac{1}{a^5}$. Therefore $\frac{1}{a-x}$ brought to a ſeries is $\frac{1}{a} + \frac{x}{a^2} + \frac{x^2}{a^3} + \frac{3}{a^4} + \frac{x^4}{a^5} +$ &c.

Art. XVI. *To involve an infinite Series to any given Power.*

Rule. Subſtitute the particular letters or numbers in the given ſeries inſtead of thoſe in the following general form

$$z^m \times : \overline{a+bx+cx^2+dx^3+ex^4}\Big|^m = z^m \times \text{ into}$$

$$\begin{aligned} & a^m \\ & +\frac{mbA}{a}.x \\ & +\frac{2mcA+\overline{m-1}.bB}{2a}.x^2 \\ & +\frac{3mdA+\overline{2m-1}.cB+\overline{m-2}.bC}{3a}.x^3 \\ & +\frac{4meA+\overline{3m-1}.dB+\overline{2m-2}.cC+\overline{m-3}.bD}{4a}.x^4 \\ & +\frac{5mfA+\overline{4m-1}.eB+\overline{3m-2}.db+\overline{2m-3}.cD+\overline{m-4}.bE}{5a}.x^5 \end{aligned}$$

where A. B. C. D. E. &c. are the coefficients of the terms immediately preceding thoſe wherein they firſt appear; and the law of continuation is evident.

Examp. Required the ſquare of $1+x+x^2+x^3+x^4+$&c. Here $z=1$, $a=1$, $b=1$, $c=1$, $d=1$, &c. and $m=2$, which values being put in the general ſeries in lieu of the letters it becomes $1+\frac{2A}{1}x+\frac{4A+B}{2}x^2+\frac{6A+3B+0}{3}x^3+\frac{8A+5B+2C-D}{4}x^4$ &c. Then the firſt term A, being 1, the 2d is $2x$, and B its coefficient is 2, the 3d term is $3x^2$, and C its coefficient is 3, and ſo on for the reſt. And the ſquare of the given ſeries is $1+2x+3x^2+4x^3+5x^4$ &c. If it was required, inſtead of ſquaring the ſeries, to extract the ſquare root thereof, the proceſs would be juſt the ſame, only m inſtead of being $=2$, would be $=\frac{1}{2}$, and in that caſe the ſeries would become $1+\frac{1}{2}Ax+\frac{A-\frac{1}{2}B}{2}x^2+\frac{A+0-C}{3}x^3+\frac{2A+\frac{1}{2}B-C-\frac{5}{2}D}{4}x^4$ &c. and hence, $1+\frac{1}{2}x+\frac{3}{8}x^2+\frac{5}{16}x^3+\frac{35}{128}x^4$&c.

Various examples might have been given to have illuſtrated this rule, but it is apprehended the above is ſufficient to ſhew its general uſe; and the nature of our plan confines me to paſs on to things more intereſting.

SECT. V.

OF EQUATIONS.

An Equation is the mutual comparing of two equal quantities differently expreſſed with the ſign of ($=$) equality between them, thus $a+b=c-d$ is an Equation, ſhewing the equality of the quantities $a+b$, and $c-d$. See Definition 24th.

Art. XVII. *To turn proportional quantities into Equations, and the contrary.*

Rule. Multiply the extremes together for one ſide of the Equation, and the two means together for the other ſide thereof, or in geometrical progreſſions when there are but three terms, ſquare the middle term for the other ſide of the Equation. If Equations are to be turned into proportions the procedure is juſt the reverſe, for each of the Equations muſt be divided into two factors, and thoſe produced from one ſide of the Equation muſt be made the extremes; and ſo thoſe of the other ſide will be the two means. Thus if the proportion $a : d :: c : x$ be given, the Equation derived from it will be $ax=dc$. Again, if the Equation $ab+ac=ca-de$ be given, it may be transformed into theſe proportions, as $a : 1 :: ca-de : b+c$; or as $a : ca-de :: 1 : b+c$; or as $b+c : 1 :: ca-de : a$; or as $b+c : ca-de :: 1 : a$; or as $1 : a :: b+c : ca-de$, or as $1 : b+c :: a : ca-de$; or as, $ca-de : b+c :: a : 1$; or as $ca-de : a :: b+c : 1$. For the Equation divides into $a\times\overline{b+c}=1\times\overline{ca-de}$ and the factors of each ſide may be made the means or extremes at pleaſure, and alſo each factor may be either of ſuch means or extremes; for by multiplying together the means, and the extremes of any of theſe proportions according to the rule, the given Equation will be produced, which ſhews that their relation with each other has been preſerved.

Art. XVIII. *To reduce an Equation.*

When Algebraical queſtions are brought to an Equation, it muſt be ſo ordered that the quantity ſought may ſtand clear on the firſt ſide of the equation, and the known quantities on the other ſide. To effect which obſerve the following directions, 1ſt. When any quantity is alike concerned on both ſides of the equation it muſt be thrown out of both. Thus if $5x+5y=4c-d+5y$. Here $+5y$ being rejected from both ſides, the Equation becomes $5x=4c-d$, the reaſon of this is evident from Axiom the 2d.

2d. When the known and unknown quantities are both on one ſide, tranſpoſe any of them to the contrary ſide and change its ſign. Thus is $4y+3b=ax-dy$. Then if y be the quantity ſought $-dy$ may be brought to the firſt ſide of the Equation, and $+3b$ may be carried to the ſecond ſide of the Equation by changing their ſigns, and hence it becomes $4y+dy=ax-3b$. This is the ſame as adding $-3b+4y$ (or ſubtracting $+3b-4y$) to both ſides of the Equation, therefore by axioms 1 and 2 the equality is preſerved. 3d. If there be fractions in the Equation, multiply both ſides by the denominators and it will be freed therefrom.

Examp. Let $\frac{a^2}{b}+c=\frac{da}{c}$. Here both ſides being multiplied by b and c (or bc) it becomes $cx^2+bc^2=bda$. This proceſs is founded on Axiom 3.

4th. When any quantity is multiplied into both ſides of the Equation (or into the higheſt term of the unknown quantity) divide the whole equation thereby.

Examp. $5bx^3=3bc$. Here divide the Equation by b, and it becomes $5x^3=3c$; again divide it by 5, and x^3 will be equal to $\frac{3c}{5}$. The truth of this appears from Axiom the 4th.

5th. If the unknown quantity is affected with a ſurd, tranſpoſe the reſt of the terms, and then involve each ſide according to the index of the ſurd. Thus if $\sqrt{x^2+ax}+d=c$, by tranſpoſing d we have $\sqrt{x^2+ax}=c-d$, and by ſquaring both ſides $x^2+ax=c^2-2cd+d^2$, and ſo the equation is freed from ſurds. This is plain from Axiom the 5th.

6th. When the ſide containing the unknown quantity is a pure power (or if being affected it has a rational root) then extract the root on both ſides of the Equation. Thus if $x^2=b^2+dc$, then $x=\sqrt{b^2+dc}$, which if b, c, and d are known quantities may be extracted in numbers, and thence the value of x will be known. So likewiſe if $x^2+6x+9=25c$, by taking the ſquare root we have $x+3=\pm\sqrt{25c}$, and by tranſpoſing 3, $x=\pm\sqrt{25c}-3$, $=\pm5\sqrt{c}-3$.

N. B. All theſe methods are to be uſed as occaſion requires, till the Equation be duly cleared.

EXAMPLES.

Examp. I. What is the value of x in this Equation $24-4x+10=60-12x$? Here $+24$ and $+10$ in the firſt ſide of the Equation being transferred to the other ſide, and $-4x$ in the ſecond ſide of the Equation being transferred to the firſt ſide, it will ſtand thus $-4x+12x=60-24-10$, viz. (by collecting the terms, See Ax. 7.) $8x=26$, and by dividing both ſides by 8, $x=\frac{26}{8}=3\frac{1}{4}$.

Examp. II. What is the value of x in this Equation $ax+b^2=\frac{ax^2+ac^2}{a+x}$. Here, by multiplying both ſides by $a+x$, we have $a^2x+ab^2+ax^2+b^2x=ax^2+ac^2$, whence (by tranſpoſition) $a^2x+ax^2+b^2x-ax^2=ac^2-ab^2$, viz. (by expunging ax^2, it being concerned with both $+$ and $-$) $a^2x+b^2x=ac^2,-ab^2$, and dividing both ſides of this Equation, by a^2+b^2, we have $x=\frac{ac^2-ab^2}{a^2+b^2}$.

Examp. III. Let $\sqrt{a^2+x^2}=\sqrt[4]{b^4+x^4}$ be given to find x. Here by raiſing both ſides of the Equation to the 4th power $a^4+2a^2x^2+x^4=b^4+x^4$, and by tranſpoſition, &c. $2a^2x^2=b^4-a^4$, and dividing by $2a^2$, $x^2=\frac{b^4-a^4}{2a^2}$; hence $x=\overline{\frac{b^4-a^4}{2a^2}}\Big|^{\frac{1}{2}}$

Examp. IV. Let $x=\sqrt{c^2+x\sqrt{b^2+x^2}}-c$. Here, $x+c=\sqrt{c^2+x\sqrt{b^2+x^2}}$, which ſquared gives $x^2+2cx+c^2=c^2+x\sqrt{b^2+x^2}$, or $x^2+2cx=x\sqrt{b^2+x^2}$; and, (dividing by x) $x+2c=\sqrt{b^2+x^2}$, which ſquared gives $x^2+4cx+4c^2=b^2+x^2$. By tranſpoſition, $4cx=b^2-4c^2$ and (dividing by $4c$) $x=\frac{b^2-4c^2}{4c}$.

Art. XIX. *To exterminate an unknown Quantity out of ſeveral Equations.*

Rule. If the quantity has but one dimenſion in the Equations, ſeek the value of the quantity to be expelled in two Equations, and put thoſe values equal to each other, or having found the value in one Equation ſubſtitute it in lieu of ſuch quantity in the reſt of the Equations. Proceed thus with another unknown quantity. But if the quantity to be exterminated be of ſeveral dimenſions, find the value of its higheſt power in two-Equations; then if the coefficients are not the ſame, multiply the leſs ſo that it may become equal to the greater. Then put theſe values equal to each other, and there will come out a new Equation, with a leſs power of the unknown quantity: and by repeating the operation, the quantity will at length be taken away.

EXAMPLES.

Examp. I. Given $7x-5y=28$, and $3x+4y=55$ to find x and y. 1ſt. Let y be exterminated. In the firſt Equation the value of y is $\frac{7x-28}{5}$, which is found by tranſpoſition and diviſion. In the ſecond Equation its value (in like manner) is found $=\frac{55-3x}{4}$. Theſe being put equal to each other we have $\frac{7x-28}{5}=\frac{55-3x}{4}$, an Equation wherein only x is concerned. Multiply this Equation by 4 and 5 (or by their product $=20$) or which is the ſame thing multiply the numerators and denominators croſs wiſe, and we have $28x-112=275-15x$. By tranſpoſition $43x=387$, and by diviſion, $x=\frac{387}{43}=9$; which ſubſtituted in either of the given equations inſtead of x, the value of y will appear. Thus if it be ſubſtituted in the ſecond Equation, then $27+4y=55$ and by tranſpoſition and diviſion $y=\frac{55-27}{4}=7$.

Examp. II. Let it be required to find the values of x, y, and z, in the three following Equations, viz. $x+y=17$; $x+z=18$; and $y+z=19$. Here, by ſubtracting the firſt Equation from the ſecond (in order to exterminate y) we have $2-y=1$, and this added to the third Equation, y is alſo exterminated; and there is found $2z=20$, and conſequently $2=10$, and $y\ (=z-1)=9$, and $x\ (=17-y)=8$.

Examp. III. Let there be given $x+y=a$; and $x^2+y^2=b$ to expunge x. Here by the firſt Equation $x=a-y$, and therefore $x^2=\overline{a-y}|^2$, which being wrote in the other Equation inſtead of x^2 we have $\overline{a-y}|^2+y^2=b$; viz. $a^2-2ay+y^2+y^2=b$; and therefore $y^2-ay=\frac{b-a^2}{2}$; a Quadratic Equation wherein y is the only unknown quantity.

Art. XX, *The Reſolution of Equations.*

In the laſt article I have ſhewn the method of freeing equations from any unknown quantity, whereby two or more equations are reduced to one, containing only one unknown quantity, the value of which, when it is a ſimple Equation, I have alſo ſhewn how to find; but it will often happen that the remaining quantity will be of ſeveral different dimenſions in the Equation, and then ſuch Equation is called a Quadratic, a Cubic, Biquadratic, &c. according to the dimenſion of the higheſt power, and to find the Root or value of the unknown quantity therein, is the buſineſs of which I ſhall now treat.

All Equations may be conſidered as compounded of thoſe of a lower order: thus if $x-b=0$, which is a Simple Equation, be ſquared, there ariſes $x^2-2bx+b^2=0$, a Quadratic; if cubed, we have $x^3-3bx^2+3b^2x-b^3=0$, a Cubic Equation, &c. It is, however, but ſeldom that Equations occur in this regular form, for the coefficients of the terms will generally be greater or leſs than are aſſigned by the involution of one quantity $x-b$, and therefore in general a Quadratic is a compound derived from $\overline{x-b}\times\overline{x-c}$; a Cubic from $\overline{x-b}\times\overline{x-c}\times\overline{x-d}$; a Biquadratic from $\overline{x-b}\times\overline{x-c}\times\overline{x-d}\times\overline{x-e}$, or from a Quadratic ſquared, &c. But the letters b, c, d, &c. may be affirmative, or ſome may be affirmative, and others negative, whereby different ſigns will be produced in the Equations anſwerable to all Caſes.

In an Equation of this ſort the whole being equal to nothing, it is obvious that at leaſt ſome or other of the factors $x-b$, $x-c$, $x-d$, &c. ſhould be equal to nothing; or the Equation (which is their product) could not be ſo. It is alſo evident, that any ſuch Equation may be divided by its factors till there remains only one factor; and as each of the inferior Equations obtained by ſuch diviſion muſt ſtill be equal to nothing, whatever factor was the diviſor, it follows that each of theſe factors are themſelves equal to nothing; and therefore b, c, d, e, &c. exhibit ſo many different values of x, with contrary ſigns; and hence every Equation has as many Roots as there are dimenſions of the unknown quantity in its higheſt power; and where b, c, d, e, &c. are found negative, x is affirmative, and where any of theſe are affirmative, x is negative. By multiplying the factors or Roots together, under different ſigns, it is obſervable, that when b, c, d, &c. are all negative, or, which is the ſame thing, when all the values of x are affirmative, the ſigns in the Equation run $+$ and $-$ alternately; but when there is a negative Root, one affirmative quantity will follow another; wherefore there will be as many affirmative Roots in Equation as there are changes of the ſigns from $+$ to $-$, and from $-$ to $+$, and all the reſt will be negative.

Theſe obſervations, however, are only applicable when all the Roots are poſſible. A Root is impoſſible, or imaginary, when b, c, d, &c. denote the Square, or other even Root, of a negative quantity, and when an Equation is wholly derived from ſuch Roots it is an impoſſible Equation; if there be one poſſible Root, the Equation will admit of one poſſible anſwer. But in applying Algebra, there will frequently be other limitations peculiar to the ſubject, whereby but one Root only will be capable of ſatisfying the enquiry, even when the reſt of the Roots are both poſſible and affirmative.

From the multiplication of the Roots, or Factors, it is further evident, and worthy of notice, that the coefficient of the ſecond term is the ſum of all the Roots with contrary ſigns: the coefficient of the third term is equal to the ſum of the Rectangles of thoſe Roots, or of all the products that can poſſibly ariſe by combining them two and two: the coefficient of the fourth term is equal to the ſum of all the products that can poſſibly ariſe by the combination of them three and three, &c. and ſo on; and the laſt term is always equal to the product of all the Roots with contrary ſigns.

Theſe things being premiſed, I proceed to ſhew how to find the Roots of Equations; and ſhall begin with Quadratics.

If it be a pure Quadratic, as $x^2=b^2$, or $x^2-b^2=0$, it is produced from the Rectangle of $x-b$ and $x+b$, and therefore it has one Root affirmative and the other negative; and the affirmative Root is equal in number to the negative Root. The Root in this caſe is had by extracting the Square Root of the number denoted by b^2. Thus if $x^2=576$, then $x=\pm\sqrt{576}=\pm 24$.

All other Quadratics are comprehended under ſome or other of the following forms, viz. $x^2+2bx\pm d=0$; or $x^2-2bx\pm d=0$; or $2bx-x^2\pm d=0$; and this laſt form by tranſpoſition (or changing the ſigns) becomes the ſame as the ſecond form, ſave that the affirmative Roots are changed into negative ones, and the negative ones into affirmative ones; wherefore it will be ſufficient to conſider the two other forms as applicable to all; and in attempting their ſolution it will be more commodious to tranſpoſe d, and then they will ſtand thus: $x^2+2bx=\pm d$, and $x^2-2bx=\pm d$. Now if to each of theſe Equations we add $+b^2$, (the ſquare of $\frac{1}{2}$ the coefficient of the ſecond term) we ſhall have in the former caſe $x^2+2bx+b^2=\pm d+b^2$; and in the latter $x^2-2bx+b^2=\pm d+b^2$, and by extracting the Square Roots, the Equations become $x+b=\sqrt{\pm d+b^2}$, and $x-b=\sqrt{\pm d+b^2}$ reſpectively; and x in the former caſe $=\sqrt{\pm d+b^2}-b$; and in the latter $=\sqrt{\pm d+b^2}+b$, which expreſſions give the affirmative values of x; but the Square Roots of the above Equations may alſo be $-x-b=-\sqrt{\pm d+b^2}$; and $-x+b=-\sqrt{\pm d+b^2}$ reſpectively, and therefore $-x$ in the former caſe $=-\sqrt{\pm d+b^2}+b$, and in the latter $=-\sqrt{\pm d+b^2}-b$. That is, if B be put $=\sqrt{\pm d+b^2}$ where d is $+$ or $-$, according as it is $+$ or $-$ in the ſecond ſide of the given Equation. Then, in the firſt caſe, where $x^2+2bx=\pm d$, the values of $\pm x$ are $\pm B\mp b$, where b is $-$ or $+$, according as x is affirmative or negative, and in the ſecond caſe, where $x^2-2bx=\pm d$; the values of $\pm x$ are $\pm B\pm b$, where b is $+$, or $-$, as x is $+$ or $-$.

EXAMPLES.

Examp. I. Let $x^2+6x=2295$ required x. Here $b=3$, and $2295=+d$; and $\sqrt{+d+b^2}=\sqrt{2295+9}=48=B$, and $\pm B\mp b=\pm 48\mp 3=+45$ and -51 for the two values of x.

Examp. II. Let $x^2-6x=1755$ be given to find the values of x. Here $b=3$, and $1755=+d$, and $\sqrt{+d+b^2}=42=B$, and $\pm x=\pm B\pm b=\pm 42\pm 3=+45$ and -39 the values ſought.

Examp. III. Let $x^2-11x=-28$. Here $b=\frac{11}{2}$, and $-28=-d$; alſo $b^2=30\frac{1}{4}$. and $\sqrt{-d+b^2}=\sqrt{-28+30.25}=\sqrt{2.25}=1.5=B$ and $\pm B\pm b=\pm 1.5\pm 5.5=+7$ and $+4$ the two values of x, which in this caſe are both affirmative.

Examp. IV. Let $24x-x^2=135$, required x. This Equation being wholly tranſpoſed $x^2-24x=-135$. Here $b=12$; and $-135=-d$. and $\sqrt{-d+b^2}=\sqrt{-135+144}=\sqrt{9}=3=B$; and $\pm B\pm b=\pm 3\pm 12=+15$ and -9 the two Roots, but the Equation having been transformed, the ſigns muſt be changed, and ſo $+9$ and -15 are the Roots required. When d is negative, and greater than b^2, the Roots are impoſſible.

Examp. V. Given $x^2-10x=-32$. Here $b=5$, and $-32=-d$, and $B=\sqrt{-d+b^2}=\sqrt{-32+25}=\sqrt{-7}$. and therefore the Roots are impoſſible, and the Equation is an impoſſible Equation.

ART. XXI. *To increaſe or diminiſh the roots of an Equation.*

RULE. For the unknown quantity ſubſtitute a new letter — the given increment, or + the given decrement. And ſubſtitute the powers thereof in the Equation inſtead of the unknown letter.

EXAMPLE.

Let the roots of this Equation $x^3+x^2-10x+8=0$ be increaſed by 2. Let $x+2=z$, or $\overline{z-2}=x$ then $x^3=\overline{z-2}|^3$; $x^2=\overline{z-2}|^2$ and $-10x=-10\times\overline{z-2}=-10z+20$, then the powers of x being actually involved, and the ſeveral terms collected, we have $x^3+x^2-10x+8=z^3-5z^2-2z+24=0$, where the roots of z are greater than thoſe of x by 2.

SCHOLIUM. By this rule all the negative roots of an Equation may be made affirmative, by increaſing them with a proper quantity.

ART. XXII. *To multiply or divide the Roots of an Equation by a given Quantity.*

RULE. Aſſume a new letter, and divide or multiply it by the given number, and ſubſtitute its powers in the Equation inſtead of the unknown quantity.

EXAMPLE.

Let the roots of the Equation $x^3-2x+\sqrt{3}+0$ be divided by $\sqrt{3}$. Here by putting $x=y\sqrt{3}$ and ſubſtituting it in lieu of x in the given Equation, there ariſes $3y^3\sqrt{3}-2y\sqrt{3}+\sqrt{3}=0$, = (by dividing by $\sqrt{3}$) $3y^3-2y+1=0$, for the Equation required.

Hence by this rule fractions or ſurds may be taken out of an Equation; by dividing the new letter by the common denominator; or by multiplying the new letter by the Surd quantity.

ART. XXIII. *To complete a deficient Equation.*

RULE. Increaſe or diminiſh the roots of the Equation by ſome given quantity; as ſhewn in ART. XXI.

EXAMP. Let $x^3+x-3=0$. Here the Equation is deficient, the 2d term being wanting. Suppoſe $z+1=x$, then $x^3=z^3+3z^2+3z+1$; this added to $x\ (=z+1)-3$, we have z^3+3z^2+4z-1, a complete Equation, in which the roots are each leſs by 1 than in the given Equation.

ART. XXIV. *To take away any Term out of an Equation.*

RULE. Take a new letter for the root, to which add an unknown quantity, and ſubſtitute this ſum and the powers thereof in the given Equation; then any term, or any of thoſe quantities wherein the new letter is of the ſame power, being put into an Equation and made equal to nothing will give the value of the unknown quantity, which being put into the Equation with the new letter, the power of the new letter, which was ſo equated, will vaniſh.

EXAMPLE.

Suppoſe $x^4-3x^3+3x^2-5x-2=0$. Put $y+e=x$.

$$\begin{array}{lllllll} \text{Then } x^4 = & y^4 & +4y^3e & +6y^2e^2 & +4ye^3 & +e^4 \\ -3x^3 = & & -3y^3 & -9y^2e & -9ye^2 & -3e^3 \\ +3x^2 = & & & +3y^2 & +6ye & +3e^2 \\ -5x = & & & & -5y & -5e \\ +2 = & & & & & +2 \end{array}$$

Then, if the ſecond term is to be taken away, we have $4y^3e-3y^3=0$; and, dividing by y^3, $4e-3=0$, or $e=\frac{3}{4}$, which if ſubſtituted in the room of e the ſecond term will vaniſh; if the 3d term is to be taken away we have $6y^2e^2-9y^2e+3y^2=0$, and dividing by y^2, $6e^2-9e+3=0$ from which quadratic Equation e may be determined; in like manner the 4th term may be taken away by ſolving a cubit Equation; the fifth by ſolving a Biquadratic, &c.

SCHOLIUM. From the above proceſs it appears that when the ſecond term is to be taken away, the value of e is obtained by dividing the coefficient of that term, by the index of the higheſt power in the given Equation, ſeeing that the coefficient of the ſecond term of the nth power of a Binomical is n. And this is the moſt uſeful caſe, the reſt being too tedious to be of real ſervice in finding the roots.

ART. XXV. *To extract the Root of a Cubic Equation.*

RULE. Take away the ſecond term of the Equation as by the laſt Article, and then it will be in this form, $x^3+ax=b$, and this general expreſſion $\overline{\frac{b}{2}+\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}}\Big|^{\frac{1}{3}}-\frac{\frac{1}{3}a}{\overline{\frac{b}{2}+\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}}\Big|^{\frac{1}{3}}}$ will give the value of x.

EXAMPLES.

EXAMP. Let $y^3+3y^2+9y=13$. Here, to deſtroy the 2d Term, put $x-1=y$, ſo ſhall $\overline{x-1}|^3+3\times\overline{x-1}|^2+9\times\overline{x-1}=13$, or (by involving the terms, &c.) $x^3+6x=20$.

Therefore $a=6$, and $b=20$; and theſe values ſubſtituted in the above form, we have $\overline{10+\sqrt{100+8}}|^{\frac{1}{3}}-\frac{2}{\overline{10\sqrt{100+8}}|^{\frac{1}{3}}}$ $=\overline{20{,}3923}|^{\frac{1}{3}}-\frac{2}{\overline{20{,}\ 3923}|^{\frac{1}{3}}}=2.732-.732=2=x$; but $x-1=y$, by ſubſtitution, and therefore $y=1$.

SCHOLIUM. The above Rule will as equally hold good when b and a are either or both of them negative. But when b is negative, and $\frac{1}{27}b^3$ is greater than $\frac{1}{4}d^2$, the Equation will be impoſſible, except when the Surd Cubic Root can be extracted; for then the irrational quantities in different parts of the Equation will deſtroy one another, and vaniſh.

However, this Rule is only calculated to ſolve Equations that have but one real Root, and two impoſſible ones.

I might further lay down particular rules for the accurate Solution of Biquadratic and other higher Equations; but they are all more curious than uſeful, and the method of approximating the Roots of Equations, of which I ſhall treat in the next Article, has the deſerved pre-eminence above all others, as well on account of its diſpatch, as of its elegance and univerſality.

ART. XXVI. *To approximate the roots of Equations in general.*

RULE. Chooſe ſome number at pleaſure to denote the unknown quantity and apply it to the given Equation, by which it will be diſcovered whether ſuch number be too big or too little. If it widely differs from the true value, try another number that approaches nearer, and by a few trials in this manner a number will ſoon be found that approaches pretty near the true value. Then aſſume ſome letter, as v, to denote the defect or exceſs of the number ſo found, and put that number + or — v inſtead of the unknown quantity in the Equation, by which a new Equation will be had affected only with v, and known quantities; wherein all the terms that contain two or more dimenſions of v may be rejected as inconſiderable in reſpect of the reſt. This done, the value of v will be found by a ſimple Equation, which added to or ſubtracted from the ſaid number according as it was taken too little or too big, will give a number ſtill nearer the truth. With this number and the letter v proceed as before, to find another value of v which muſt be applied as above; repeat the operation till the quantity, which was unknown, be determined to a ſufficient degree of accuracy.

EXAMPLE.

Let $x^3+24x=587914$, to find x. By a few trials it will be found that x is ſomething above 80; therefore let $80+v=x$; then $x^3=512000+19200v+1680v^2+v^3$, and $24x=1920+24v$. Therefore (rejecting thoſe terms affected with v^2 and v^3) $513920+19224v=587914$, and $v=\frac{587914-513920}{19224}=\frac{73994}{19224}=3.8$; this added to 80 gives 83.8 for the approximate value of x; this being ſubſtituted in the Equation, it will be found too great; therefore, for another operation, take $83.8-v=x$, and $x^3=588480.472-21067.32v$, and $24x=2011.2-24v$, and conſequently $590491.672-21091.32v=587914$, and $v=\frac{2577.672}{21091.\ 32}=0.1222$ nearly. Hence $x=83.8-0.1222=83.6778$. true to five figures, and the 6th being only too much by 2.

The operation repeated, will give the anſwer true to eleven figures. But when five or ſix figures of the Root have been obtained, and ſtill more exactneſs is requiſite, it will ſhorten the operation to ſeek a correction for v inſtead of one for the whole Root, which will be had by ſubſtituting the laſt value of v + or — (new) v inſtead of the laſt v in the Equation, including all the powers of the laſt v; but (in the Equation thence ariſing) rejecting thoſe of new v as before.

Thus in the laſt Example the whole Equation including the terms affected with v^2 and v^3 is $513920+19224v+1680v^2+v^3=587914$, or $19224v+1680v^2+v^3=73994$, and in this Equation putting $3.8-v$ inſtead of v, and rejecting the terms of v^2 and v^3 as before a correction will be obtained for the laſt found v, which will give the anſwer as above. In like manner a ſecond or a third, &c. correction may be found, to any degree of accuracy. This Rule doubles the number of figures true in the Root at each Operation. If the term wherein v^2 is found be retained, v will be had by ſolving a Quadratic, and then treble the number of figures will be had each time; wherefore, if the firſt figure only be taken true, nine or ten figures will be had at two Operations.

From this principle may be deduced various Theorems for ſolving particular Equations, as well as general formulas adapted to all, of which I ſhall give an inſtance or two, and then conclude the Article.

Let r be a number taken near to the true root; and v (as before) $=$ its exceſs or defect. Then if $x^2+bx=c$ be a quadratic, then $r\pm v=x$, and $x^2=\overline{r\pm v}^2=r^2\pm 2rv+v^2$; and $bx=br\pm bv$; hence $r^2+br\pm\overline{2r+b}.\times v+v^2=c$, and by tranſpoſition and diviſion $v=\dfrac{c-r^2-br}{\pm\overline{2r+b}+v}$, which is a general formula for all quadratics, obſerving that when b is negative in the given equation, that is, when the 2d term is negative, then $-br$ in the numerator becomes $+br$, and $+b$ in the denominator becomes $-b$; alſo, if the given equation be $x^2=c$, then $b=0$, and thoſe terms wherein it is concerned will vaniſh, and the expreſſion will be $\dfrac{c-r^2}{\pm 2r+v}$ which is the common rule for extracting the ſquare root, only it is uſual to take r leſs than juſt, and ſo the negative ſign is excluded from the denominator. To give an Example of this method,

Let $x^2+6x=61495=c$. Here by trial it will be found that x is above 200: therefore let $200=r$; then $-b=-1200$; and $c-r^2-br=20295$: the method of performing the diviſion is as follows:

OPERATION.

$$\begin{array}{r l}
2r+b=406 & \\
v'=\underline{\ \ 40} & \Big)\ 20295\ \Big(\ 45=v,\ \text{and}\ r+v=200+45= \\
2r+b+v'=446 & \quad 1784 \qquad\qquad\qquad\qquad (245=x. \\
\underline{40} & \quad \overline{} \\
2r(new)+b=486 & \Big)\ 2455 \\
v''=\underline{\ \ 5} & \Big)\ 2455 \\
2r+b+v''=\underline{\underline{491}} & \quad \overline{} \\
 & \quad \dots
\end{array}$$

Again, for a cubic Equation. Let $x^3+bx^2+dx=c$. Put $r\pm v=x$. So will $x^3=r^3\pm 3r^2v+3rv^2\pm v^3$; $bx^2=br^2\pm 2brv+bv^2$, and $dx=dr\pm dv$. Hence $r^3+br^2\pm\overline{3r^2+2br+d}\times v+\overline{3r+b}\times v^2+dr=c$ (v^3 being rejected as ſmall in compariſon of the reſt); and by tranſpoſition $\pm\overline{3r^2+2br+d}\times v,+\overline{3r+b}\times v^2=c-r^3-br^2-dr$; and $v=\pm\dfrac{c-r^3-br^2-dr}{\overline{3r^3+2br+d}+\overline{3r+b}.v}$ to be wrought after the ſame manner as the laſt Example; or if $\pm\dfrac{\overline{3r^2+2br+d}}{3r+b}$ be put $=2m$, and $\dfrac{c-r^3-br^2-dr}{3r+b}=p$ then (per quadraties) $v=\sqrt{p+m^2}\pm m$. When three or four figures are found they muſt be taken for new r, and the operation muſt be repeated.

Or, if $\pm\overline{3r^2+br+d}$ be put $=g$, and $\overline{3r+b}=h$, and $c-r^3-br^2-dr=p$, then (ſince $\dfrac{p}{g}=v$ nearly) $\dfrac{p}{\pm g+h\times\frac{p}{g}}$ will be $=v$ more nearly. Or the ſame may be rendered general, after this manner.

Let n be the higheſt power, and A, B, C, &c. be the aggregate coefficients of v, v^2, v^3, &c. and if the given Equation be $x^n,+ax^{n-1}+bx^{n-2}+cx^{n-3}+$ &c. (to px) $=\mathrm{N}$, then $\pm\mathrm{A}v+\mathrm{B}v^2\pm\mathrm{C}v^3+$ &c. $=\mathrm{N}-r^n-{}^n a r^{n-1}-br^{n-2}-cr^{n-3}-$ &c. (to pr) $=\mathrm{P}$; and, by taking the firſt two terms of the ſeries as ſufficient for an approximation, we have $\pm\mathrm{A}v+\mathrm{B}v^2=\mathrm{P}$, and therefore $v=\sqrt{\dfrac{\mathrm{P}}{\mathrm{B}}+\dfrac{\mathrm{A}^2}{4\mathrm{B}^2}}\mp\dfrac{\mathrm{A}}{2\mathrm{B}}$; or $v=\dfrac{\mathrm{P}}{\pm\mathrm{A}+\mathrm{B}v}$; and, taking the firſt approximate, $\dfrac{\mathrm{P}}{\mathrm{A}}$ for v, we have $\dfrac{\mathrm{P}}{\pm\mathrm{A}+\frac{\mathrm{BP}}{\mathrm{A}}}$, for the value of v, either of which Rules are general, and will converge ſufficiently ſwift.

ART. XXVII. *To approximate the Roots of Exponential Equations.*

RULE. Let $x^x=c$ be given to find x. Seek a number (by trial) which ſhall be near the Root, and take the logarithm thereof; multiply this logarithm by the ſaid number, then take the difference between this product and the log. of the given number c, and note it down with the ſign + or — according as the product exceeds or falls ſhort of the log of c. Proceed in like manner with another number (taken for the Root) and by the method of trial and error as given in our New Syſtem of Arithmetic find the value of x.

If it be not exact enough, freſh numbers may be taken very near the Root, whereof the value of x laſt found may be one, and by thus repeating the operation as often as ſhall be requiſite, x may be had to any degree of accuracy.

EXAMP. Let $x^x=256$, required x. Suppoſe $x=3$; then the logarithm of 256 is 2,40824, and the logarithm of $3=,4771213$; this multiplied by 3 the product will be found deficient of 2.40824, by 1.07788, and therefore the ſuppoſition 3 is too little.

Again, ſuppoſe $x=5$; then its logarithm .69897 multiplied by 5 will be found too much by 1,08661; and theſe ſuppoſitions and errors being managed according to the method above-mentioned, x will be found $=3.996$, erring only 4 in the laſt figure, the true anſwer being four; and by taking 3.996 as a new ſuppoſition, along with ſome other number nearly equal to it, the anſwer would be had with far more exactneſs. There are other ways of ſolving theſe Equations, but none that will more quickly approximate to the true value than this exceeding eaſy one.

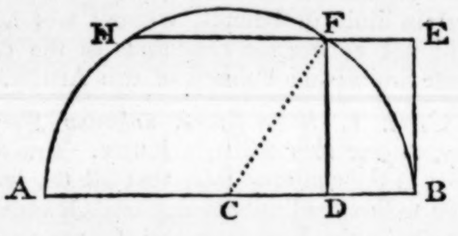
SECTION VI.

CONSTRUCTION OF EQUATIONS.

WHEN in the Solution of an Equation, ſtrict accuracy is not required, the anſwer may be determined geometrically, by drawing right lines or curves after ſuch a manner, as, by their interſections, ſhall limit and determine its Roots: but ſince the extraction of Roots by approximation has been brought to ſuch perfection, ſo that either a few, or as many figures as one pleaſes, may be readily obtained, Geometrical Conſtructions have, in a great meaſure, been laid aſide, particularly in Equations of high dimenſions, where recourſe muſt be had to the Conic Sections and other Curves ſtill more difficult to delineate; as the trouble in ſuch caſes would be almoſt infinite, and at laſt fail of producing a correct anſwer.

I ſhall therefore only give the conſtruction of Quadratic and Cubic Equations, which may be done without much pains by means of a Circle paſſing over thoſe of the higher orders, as well as thoſe of Simple Equations for which no preciſe Rule can be given; but the methods will be different as the unknown quantity is differently entangled with others, and the aſſiſtance alſo of Geometrical Propoſitions, too various to enumerate here, are frequently called in.

ART. XXVIII. *To conſtruct Quadratic Equations.*



PROBLEM 1. To extract the Square Root, or to find the Root or Side of a given Square, as x in this Equation, $x^2=nm$. RULE. The given quantity being divided into two factors, as n and m, take AD $=$ one factor (n) and DB $=$ the other (m); divide AB equally in c, and from thence as a center deſcribe the Semicircle AFB; erect from D perpendicular to AB, and DF will be equal to x, for by the Property of the Circle, AD ($=n$) $\times$ DB ($=m$) $=\mathrm{DF}^2$, and therefore DF$=x$.

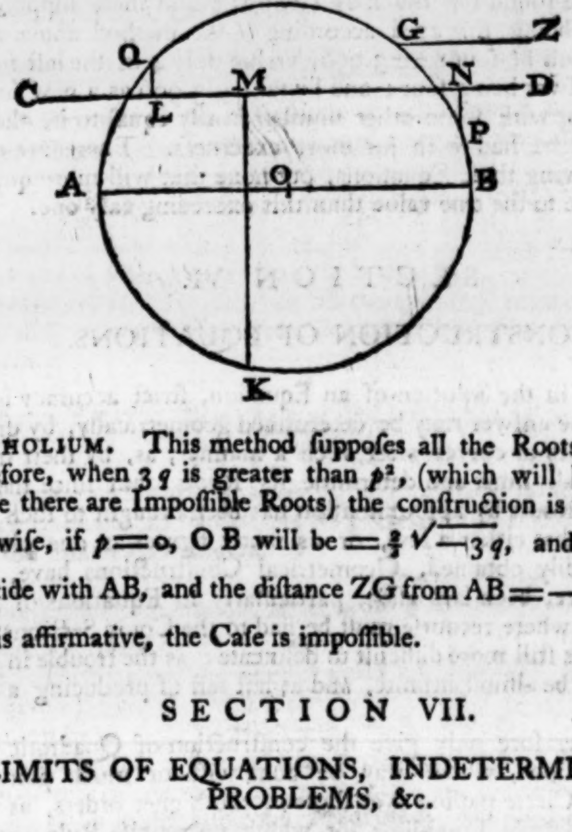
PROB. 2. To conſtruct a Quadratic of this form, $x^2\pm bx=cd$. RULE. Find the Side of a Square equal to the rectangle cd by the laſt Problem, which call n, then from any point C in a line AB drawn at pleaſure, ſet off, to the right, CD $=\frac{1}{2}b$, if b is affirmative; but to the left if b is negative: erect a perpendicular from D, and take DF$=n$, then from C as a center, with the Radius CF deſcribe the Circle AFB, ſo will BD and DA be the two Roots, that to the right hand of D being affirmative, and that to the left negative.

PROB. 3. To conſtruct a Quadratic Equation of this kind, namely, $x^2\pm bx=-nn$. RULE. Here the given Quantity $-nn$ being divided into two equal factors (but of contrary affections) by Problem 1, namely, $+n$ and $-n$, let a circle be deſcribed from any point C as a centre in the right line AB: with the radius $=\frac{1}{2}b$, erect a perpendicular at B, on the right, if it be $+b$ (but, at A on the left if it is $-b$); take BE$=n$; through E draw EFH parallel to AB, interſecting the Circle in F and H, ſo will EF and EH be the two Roots required, which if they lie towards the right of E are affirmative; but, if towards the left, they are negative.

N. B. If the parallel does not cut the circle or touch it, the Equation is impoſſible,

ART. XXIX. *To conſtruct Cubic Equations.*

Let the Equation be $x^3\pm px^2\pm qx=r$; to conſtruct which, obſerve this Rule, with the Radius $\frac{2}{3}\sqrt{p^2-3q}$, deſcribe the Circle BGAK (as in the following figure) drawing the diameter AB and CD parallel thereto, above or below the ſame, at the diſtance of $\frac{1}{3}p$, according as p is + or —; then draw ZG parallel to AB, and above or below it, at the diſtance of $\dfrac{qr-pq}{p^2-3q}+\frac{2}{3}p$, as the ſame diſtance ſhall be an affirmative or negative quantity; cutting the Circle in G. Alſo take the arch BP $=\frac{1}{3}$BG, and let PQ, QK and KP divide the whole Circle into three equal parts. Let fall the perpendiculars QL, KM and BN upon the line CD, and they will be the Roots of the Equation, thoſe which are affirmative being above the line, but thoſe which are negative, below it.



Scholium. This method ſuppoſes all the Roots real, and therefore, when $3q$ is greater than p^2, (which will be the caſe where there are Impoſſible Roots) the conſtruction is impoſſible. Likewiſe, if $p = 0$, O B will be $= \frac{2}{3}\sqrt{-3q}$, and C D will coincide with AB, and the diſtance ZG from AB $= -\frac{3r}{q}$: and if q is affirmative, the Caſe is impoſſible.

SECTION VII.

LIMITS OF EQUATIONS, INDETERMINATE PROBLEMS, &c.

Art. XXX. *To find the Limits of Equations.*

WHEN an Equation contains ſeveral unknown quantities, it will admit of an infinite number of Solutions, if both fractional and negative numbers are admitted; for all of them, except one, may be taken at pleaſure, and their values being aſſigned and ſubſtituted in the Equation that ſingle quantity will be determined. However, ſometimes queſtions are ſo propoſed as not only to exclude negative quantities, but fractional quantities alſo; and an Equation under ſuch circumſtances will be confined to a determinate number of Solutions; for the unknown quantities will have certain limits or bounds, without which, if they be taken they will not anſwer the conditions of the caſe in hand. To aſſign thoſe limits is the buſineſs of this Article.

Case I. *When ſeveral unknown Quantities are in one Equation, to find their limits.* **Rule.** Tranſpoſe the negative Quantities to the contrary ſide, that all the terms may be affirmative; then to find the limits of any one Quantity, ſuppoſe all the reſt to vaniſh in the Equation, and ſo the value of that one will become determinate, and will be one limit thereof. And to know which limit it is, ſuppoſe the other Quantities to increaſe and become of ſome certain value: then if, by this procedure, the value of the unknown quantity under conſideration increaſes, it is the leaſt limit; but if it decreaſes, it is the greateſt.

This Rule includes fractional Quantities. If, however, fractional Quantities are to be excluded, then, inſtead of ſuppoſing the other Quantities to vaniſh, put each of them $= 1$, and an Equation will be had from which the limit of the remaining quantity will be determined as before. Proceed in the ſame manner to find the limits of the reſt of the unknown Quantities.

Examp. Let $4x + 5y = 67$, to find the limits of x and y, including fractions. Let $y = 0$, or be ſuppoſed to vaniſh, and then $4x = 67$, and $x = 16\frac{1}{4}$. Now let y be ſuppoſed $=$ to ſome quantity, and then it is plain, that while y increaſes, x decreaſes; therefore $16\frac{1}{4}$ is the greater limit; whence x is leſs than $16\frac{1}{4}$.

If $x = 0$, then $5y = 67$, and $y = 13\frac{2}{5}$. If now y be ſuppoſed to increaſe, it is plain x will decreaſe, and therefore $13\frac{2}{5}$ is the greater limit of y. Whence y is leſs than $13\frac{2}{5}$; and the leſs limit of both x and y is 0.

Again, let the ſame be propoſed, excluding fractions; then to find a limit for x, put $y = 1$, and the Equation becomes $4x + 5 = 67$; or $4x = 62$, and $x = 15\frac{1}{2}$, its greater limit; viz. x is leſs than $15\frac{1}{2}$. Alſo by putting $x = 1$, we have $5y + 4 = 67$, or $5y = 63$, and $y = 12\frac{3}{5}$; and hence y is leſs than $12\frac{3}{5}$; the leſs limit of both x and y is 1, viz. neither x nor y can be leſs than 1.

Case II. *When three or more unknown Quantities are in two Equations, to determine their Limits.*

Rule. Having pitched upon a quantity to be limited, expunge one of the other quantities, and there will be had one limiting Equation. Then do the ſame with another unknown quantity, and there will be had another limiting Equation; from each of which Equations, find a limit for the quantity pitched on.

Examp. Let $x + y + z = 56$, and $32x + 20y + 16z = 1232$, to limit x. Firſt, in order to exterminate y, multiply the firſt Equation by 20, and there will be $20x + 20y + 20z = 1120$. Subtract this from the ſecond Equation, and $12x - 4z = 112$. Then (excluding fractions) the leſs limit of x in this Equation is $9\frac{2}{3}$.

Again, to exterminate z, multiply the firſt Equation by 16, and ſubtract the product from the ſecond Equation, and you will have $16x + 4y = 336$. And the greater limit of x, in this Equation, is $20\frac{1}{4}$. Hence x is greater than $9\frac{2}{3}$, and leſs than $20\frac{1}{4}$. In like manner may y and z be limited; and ſo alſo for any other Equation.

Scholium. When three numbers are ſought by two Equations, all the values of each of them, in whole numbers, make three ſeries of Arithmetical Progreſſion, taken within their proper limits.

Art. XXXI. *Of indeterminate Problems.*

Lemma. Let $\frac{ax \pm b}{c}$ be an Algebraic Fraction in its loweſt terms, x being indeterminate, and a, b, and c, being given whole numbers; then the leaſt integer for the value of x, that will alſo cauſe the value of the ſaid Fraction, to be an integer, will be found by the following method.

Divide the denominator (c) by the coefficient (a) of the indeterminate quantity; alſo divide the diviſor by the remainder, and the laſt diviſor, again, by the laſt remainder, and ſo on till an unit only remains. Write down all the quotients in a line as they follow, under the firſt of which write an unit, and under the ſecond write the firſt; then multiply theſe two together; and, having added the firſt term of the lower line (or an unit) to the product, place the ſum under the 3d Term of the upper line; multiply in like manner the next two correſponding terms of the two lines together, and having added the ſecond term of the lower to the product, put down the reſult under the fourth term of the upper one. Proceed on in this way till you have multiplied by every number in the upper line. Then multiply the laſt number thus found, by the abſolute quantity (b) in the numerator of the given fraction, and divide the product by the denominator; ſo ſhall the remainder be the true value of x required, provided that the number of terms in the upper line be even, and the ſign of b be negative; or that the number be odd, and the ſign of b be affirmative, but if the number of terms be even, and the ſign of b be affirmative, or vice verſa, then the difference between the ſaid remainder and the denominator of the fraction, will be the true anſwer.

N. B. In this method it is ſuppoſed that a is leſs than c, and that they are prime to each other; for were they to admit of a common meaſure, whereby b is not diviſible, no integer could be aſſigned for x, ſo as to give the value of $\frac{ax+b}{c}$ an integer.

Examp. Let the given quantity be $\frac{71x+10}{89}$, then the operation will ſtand as below.

$$\begin{array}{l} 71)\,\underline{89}\,(1 \\ \quad 18)\,\underline{71}\,(3 \\ \qquad 17)\,\underline{18}\,(1 \\ \qquad\qquad 1 \end{array} \qquad\qquad \begin{array}{rrrrl} 1 & 3 & 1 & & \text{Quotients} \\ 1 & 1 & 4 & 5 & \\ & & & \underline{10} & = b \\ & & & 50 & \textit{Product.} \end{array}$$

Now if the Product (50) be divided by 89, the remainder is 50, which is therefore $=$ the leaſt value of x.

Quest. I. required the leaſt whole number, which, being divided by 17, ſhall leave a remainder of 7; but, if divided by 26, the remainder ſhall be 13? Here let $x =$ the quotient by 17, and then will $17x + 7 =$ number ſought; alſo, ſince this number, when 13 is ſubtracted from it, is diviſible by 26, it follows, that $\frac{17x + 7 - 13}{26}$ or $\frac{17x - 6}{26}$ muſt be a whole number, from which fraction x will be found by the above lemma $= 8$; and conſequently $17x + 7 = 143$ is the number ſought.

Quest. II. Given $24x - 13y = 16$ to find the leaſt values of x and y in whole numbers. Here by tranſpoſing $-13y$, and dividing by 24, we have $x = \frac{13y + 16}{24}$; and by the Lemma, the leaſt value of y in the fraction $= 8$; and therefore the leaſt value of $x = 5$.

Quest. III. How many different ways is it poſſible to pay 100 £. in guineas and piſtoles only; a guinea being 21*s.* and a piſtole 17? Put $x =$ number of guineas, and $y =$ number of piſtoles; then $21x + 17y = (100 \times 20) = 2000$ by the queſtion; and therefore $x = \frac{2000 - 17y}{21} = 95 + \frac{5 - 17y}{21}$, $=$ a whole number; and therefore (by tranſpoſition) $\frac{17y - 5}{21}$ is alſo a whole number; whence by the lemma, the leaſt value of y is 4; and therefore the correſponding or greateſt value of $x = 92$. Now to find the leaſt value of x and the greateſt value of y, take the value of y in terms of x: and $y = \frac{2000 - 21x}{17} = 117 - x - \frac{4x + 11}{17} =$ a whole number; and therefore $\frac{4x - 11}{17} =$ a whole number, and by the Lemma, the leaſt value of x is 7, and the correſponding, or greateſt value of $y=109$; now ſince the ſeveral values of x are, as is evident, in an arithmetical progreſſion whoſe common difference is 17, and thoſe of y, in a like progreſſion, whoſe common difference is 21, the intermediate values of x and y are eaſily determined, and are as under:

$$x = 92,\ 75,\ 58,\ 41,\ 24,\ 7,$$
$$y = 4,\ 25,\ 46,\ 67,\ 88,\ 109$$

N. B. Having found the greateſt value of either of the unknown quantities, the leaſt value thereof may be more readily obtained thus: Divide the greateſt value by the coefficient of the other unknown quantity, and the remainder will be the leaſt value. Alſo the quotient $+1$ will be the number of anſwers. This however ſuppoſes the coefficients to be prime to each other; and, therefore, when they are not ſo, the Equation muſt be reduced by dividing by the greateſt common meaſure.

QUESTION IV. The reckoning of a certain number of men and boys came to 23 ſhillings; to the defraying of which each man paid 3s. 6d. and each boy 1s. 6d. What number of men and boys were there in company?

Let $x=$ the number of men, and $y=$ the number of boys; then $7x+3y=46$ per queſtion, and $x=\frac{46-3y}{7}=6-\frac{3y+4}{7}$ $=$ a whole number; and therefore $\frac{3y-4}{7}=$ a whole number; whence the leaſt value of y is 6, and conſequently the greateſt value of x is 4; and this, divided by 3, leaves a remainder of 1 for the leaſt value of x, and 13 is the correſponding value of y. Alſo the quotient $+1=2$, which ſhews that there are no more ways of paying the reckoning. But as the queſtion ſuppoſes a plurality, both of men and boys, the two former numbers, only, can ſatisfy the demand. Hence, there were 4 men and 6 boys.

QUESTION V. Required the leaſt integer, which being divided by 4, 5, and 6, there ſhall remain 1, 2, and 3, reſpectively.

Here let $x=$ the quotient by 4, then $4x+1$ will be the required number; and, by the ſecond condition of the queſtion, $\frac{4x+1-2}{5}=\frac{4x-1}{5}=$ whole number; then by the lemma $x=4$; and $4x+1=17=$ the leaſt whole number that will anſwer the two firſt conditions. Now the leaſt whole number that is diviſible by 4 and 5, will (as they are prime to each other) $=4\times5=20$; then ſince the required number, by the nature of the queſtion, muſt be ſome multiple of 20 increaſed by 17, it is evident that it may be repreſented by $20y+17$; and this number, leſs 3, is alſo diviſible by 6; therefore, $\frac{20y+17-3}{6}$ is a whole number; viz. $3y+2+\frac{2y+2}{6}=$ a whole number; and therefore, $\frac{2y+2}{6}$, or $\frac{y+1}{3}=$ a whole number; and, by the lemma, the leaſt value of y is 2; and conſequently, $20y+17=57$, $=$ the leaſt whole number; which being divided by 4, 5, and 6, reſpectively, will leave the given remainders 1, 2 and 3. In like manner the method may be extended to any numbers of diviſors and given remainders, by proceeding ſtep by ſtep, till a number is found that will anſwer the whole; and conſequently the ſame will be applicable in the ſolution of indeterminate Equations, where three, four, or more quantities are concerned. But when the number of the unknown quantities exceed the number of Equations by more than one, the limits of the quantities muſt be found by ART. 30, and, then the values of ſome unknown quantity muſt be aſſumed, at repeated operations $=$ to the ſucceſſive numbers between its leaſt and greateſt limits, and ſo all the values of the reſt of the unknown quantities will be determined by the preceding methods; viz. for inſtance, if there be three unknown quantities in one Equation, and if it is found that a quantity cannot exceed 10 nor be leſs than 1, aſſume its value $=1$, and then the Equation will be reduced to two unknown quantities, to be determined as hath been already ſhewn. This done, aſſume its value $=2$, and determine the reſt as before; then put 3 for its value, and ſo on, till all the numbers from its leaſt to its greateſt limits are exhauſted. The ſum of all the anſwers thus obtained, will exhibit all the poſſible ways by which the queſtion can be ſolved.

ART. XXXII. *Of rational Square and Cube Numbers.*

For queſtions of the following nature no certain rule can be given, but the methods of ſolving them as well as thoſe of ſome others that come under the laſt article, reſt chiefly in the invention of the artiſt, whoſe penetration and ſagacity, alone, muſt ſuggeſt what ſteps will be requiſite to accompliſh the end of his enquiries. On this account, and becauſe the limits of our plan will not permit us to enlarge, I ſhall only lay down ſome general obſervations reſpecting them, with a few examples, and then add ſome queſtions for the further illuſtration of what has been delivered in this Syſtem; at the ſame time informing the contributors to this undertaking, that many intereſting matters wherein Algebra is applied will be occaſionally interſperſed in the courſe of the work under their proper heads, ſo that it ſhall unequivocally merit the Title of "THE NEW ROYAL ENCYCLOPÆDIA," and not, like a certain upſtart production, ſkip over ſyſtems by referring to other articles where the ſubjects are alſo wholly untouched on.

Obſervations on Square Numbers.

1ſt. All even ſquare numbers are diviſible by 4, and therefore if a number conſiſt of two even ſquare numbers, it will alſo be diviſible by 4.

2d. Any odd ſquare number divided by 4, leaves a remainder of 1, and therefore, if a number, conſiſting of two odd ſquare numbers, be divided by 4, there will be a remainder of 2.

3d. It follows from the above, that if a number, conſiſting of an even and an odd ſquare number, be divided by 4, there will be a remainder of 1.

4th. Hence alſo, if any number which is compoſed of two ſquare numbers, be divided by 4, it cannot leave a remainder of 3; and conſequently a number, which is compoſed of two ſquare numbers, cannot fall within this progreſſion, 3, 7, 11, 15, 19, 23, &c.

5th. Any number ending in 2, 3, 7, or 8, is not a ſquare number.

6th. The ſum of any number of terms of the ſeries, 1, 3, 5, 7, 9, 11, &c. beginning with the firſt, is a ſquare number, whoſe root is equal to the number of terms.

7th. The difference between any two ſquare numbers is equal to the product of the ſum and difference of their roots. Thus, if a and b be the roots, then $\overline{a+b}\times\overline{a-b}=a^2-b^2$; and the ſame is alſo equal to the ſum of the two roots, together with twice the ſum of the roots of all the intermediate ſquare numbers. Thus the difference between 36 and $9=\overline{6+3}+2\times\overline{\sqrt{16}+\sqrt{25}}=9+18=27$.

In attempting to ſolve queſtions of this claſs, the chief point in view, is to make ſuch aſſumptions for the root of the required ſquare or cube, as ſhall, when involved, cauſe either the given number, or the higheſt power of the unknown quantity, to vaniſh out of the Equation, whereby at length there will be only one dimenſion of the unknown quantity, and ſo the queſtion will be ſolved, by reducing the Equation.

EXAMPLES. QUESTION I.

What two ſquare numbers are thoſe, the difference whereof is 57? Here I try to divide 57 into two unequal integer factors, which in any caſe may be done if one of them is taken an unit. But here I find 3 and 19 will do. Hence as the rectangle of the ſum and difference of the roots is equal to the difference of the ſquares, $=$ to the rectangle of 3 and 19, I conclude that the ſum of the two roots is 19 and the difference 3: then if $x=$ greateſt root, and $y=$ leſs, $x+y=19$ and $x-y=3$; and adding the two Equations together, and dividing by 2, we have $x=11$, and conſequently $y=8$; or, which is a well known theorem, half the ſum $+$ half difference $=$ greater number, and half ſum $-$ half difference $=$ leſs number. Hence the two ſquare numbers are 121, and 64 reſpectively. If an unit had been taken for one of the factors, then $\frac{56+1}{2}=29$ for the greater root, and $\frac{57-1}{2}=28$, the leſs root, and the ſquare numbers themſelves are 841, and 784, reſpectively, which likewiſe anſwer the conditions of the queſtion.

SCHOLIUM.

In order to have the anſwer in whole numbers; if the given difference be an odd number, both the factors muſt be taken odd, which may always be done by means of an unit; and, ſo it will always be a poſſible caſe. But if the propoſed difference be an even number, it muſt be divided into factors that are even, or the anſwer will not be had in whole numbers: when it is a poſſible caſe, one of the factors may be 2. By thus dividing the given difference into factors all the poſſible anſwers will be readily exhibited. If fractional numbers are included, the anſwers will be innumerable.

QUEST. II. To divide a given ſquare number (100) into two other ſquare numbers. Let the given ſquare number $(100)=b^2$, and put $x^2=$ one of its parts, ſo will $b^2-x^2=$ the other part, which is alſo a ſquare number. Aſſume this number alſo $=\overline{rx-b}|^2$; then theſe values being put equal to each other, and the Equation reduced, $x=\frac{2br}{r^2+1}$; and by ſubſtituting this in lieu of x in the aſſumed value of the other root, viz. $rx-b$, we have $\frac{br^2-b}{r^2+1}$. And hence $\frac{2br}{r^2+1}$, and $\frac{br^2-b}{r^2+1}$, are the roots of the required ſquares; where r may be any number (above 1) taken at pleaſure. Now if the value of b $(=10)$ be reſumed, and r be taken $=2$, the roots of the required ſquares will be 8, and 6 reſpectively; and conſequently the ſquare numbers are 64 and 36. If no value of r will give the anſwer in whole numbers, the given ſquare number is not compoſed of two integer ſquares.

QUEST. III. To find a ſquare number, which if multiplied by a known ſquare number $(=9)$ and a given number (288) be added to the product, the reſult ſhall be a ſquare number. Put $9=a^2$; $288=d$; and $z^2=$ the required number. Then $a^2z^2+d=$ a ſquare number $(=y^2)$ per queſtion. Aſſume $v-az=y$, then

$y^2 = v^2 - 2vaz + d = v^2 - 2vaz + a^2z^2$. Now, putting theſe two values of y^2 equal to each other, viz. $a^2x^2 + d = v^2 - 2vaz + a^2z^2$ and reducing the Equation, we have $z = \frac{v^2 - d}{2av}$, where v may be taken at pleaſure: but with this proviſion, if the anſwer is required in whole numbers, that $v^2 - d$, will divide by $2av$. In the above Example take $v = 24$, and reſume the values of a $(=3)$ and d $(=288)$, and z is had $=2$; hence $z^2 = 4$, which numbers anſwers the demands of the queſtion.

QUEST. 4. To divide a given number (25) conſiſting of two known ſquare numbers (16 and 9) into two other ſquare numbers.

Put $16 = d^2$ and $9 = b^2$, and aſſume $ra - d =$ ſide of one ſquare, and $sa - b =$ ſide of the other, then $\overline{ra - d}^2 + \overline{sa - b}^2 = d^2 + b^2$ (per queſtion). By involution and tranſpoſition $r^2a^2 + s^2a^2 = 2rad + 2sab$; and dividing by $ar^2 + as^2$, we have $a = \frac{2rad + 2abs}{ar^2 + as^2} = \frac{2rd + 2bs}{r^2 + s^2}$, and this ſubſtituted for a in the aſſumed expreſſions, $ra - d$, and $sa - b$, they become $\frac{dr^2 + 2bsr - ds^2}{r^2 + s^2}$, and $\frac{2rds + bs^2 - br^2}{r^2 + s^2}$, for the two roots of the ſquare numbers required. Now, if the values of d and b be reſumed, and r be taken $= 2$, and $s = 1$, we ſhall have $\frac{24}{5}$ and $\frac{7}{5}$ for the roots; and therefore $\frac{576}{25}$ and $\frac{49}{25}$ are the ſquare numbers required.

N. B. r and s may be any numbers whatever, provided r be greater than s, and that their ratio be not as that of d to b, or of $d + b$ to $d - b$. In Ronayne's Algebra, through taking r leſs than s, and aſſuming $ra + b =$ one of the given ſides, the ſolution to this problem is wrong.

QUEST. 5. To find three cube numbers, whoſe ſum may be both a ſquare and a cube number.

Put a, e, and y, for their reſpective roots, and $x^6 =$ ſum of their cubes; then, $a^3 + e^3 + y^3 = x^6$ per queſtion. Aſſume $\frac{x^4}{a^2}v - a = e$, and $x^2 - v = y$; then $a^3 + \overline{\frac{x^4}{a^2}v - a}\Big|^3 + \overline{x^2 - v}\Big|^3 = x^6$; the compound parts of which Equation being involved, and then the whole properly reduced, v is found $= \frac{3a^3x^2}{x^6 + a^3}$, where x and a may be taken at pleaſure; and this value of v being ſubſtituted in the aſſumed values of e and y, above ſpecified, they will become known. If $x = 1$, and $a = \frac{1}{2}$, then $v = \frac{1}{3}$, whence $e = \frac{5}{6}$, and $y = \frac{2}{3}$, and conſequently the cube numbers are $\frac{1}{8}$, $\frac{125}{216}$, and $\frac{8}{27}$, which fulfil the conditions of the queſtion; their ſum being $(=1)$ both a ſquare and a cube number. And by taking different values for x and a, various anſwers may be obtained.

SECT. VIII.

ALGEBRAIC QUESTIONS.

QUEST. I. What two numbers are thoſe, whereof the ſum is 108, and the proportion of the leſs to the greater as 5 to 7?

Let $x =$ the greater number; then $108 - x =$ the leſs. And as $108 - x : x :: 5 : 7$ per queſtion. This brought into an Equation by Art. 17, we have $5x = 756 - 7x$, and by tranſpoſing $7x$, there is $12x = 756$: hence, by dividing by 12, $x = 63$, the greater number; and $108 - 63 = 45$, the leſs number.

QUEST. II. There are three numbers in arithmetical progreſſion; the common difference is 2; and the product of the ſaid numbers is 960. What are thoſe numbers?

Let $x =$ the middle term of the progreſſion, and then $x + 2$, and $x - 2$, will be the two other terms: and $x \times \overline{x + 2} \times \overline{x - 2} = 960$ per queſtion. The terms being actually multiplied, $x^3 - 4x = 960$; which Equation ſolved, either by Art. 25, or Art. 26, gives $x = 10$; and therefore the three numbers are 8, 10, and 12.

QUEST. III. A ſervant bought apples at 6 a penny, and pears at 5 for two-pence. The number of apples and pears together was an hundred; and the money given for them was 2s. 2d. I demand how many there were of each ſort?

Let $a =$ the number of apples; then $100 - a$ will be the number of pears: and, as $6 : 1\text{d} :: a : \frac{a}{6} =$ price of the apples. Alſo, as $5 : 2\text{d} :: 100 - a : \frac{200 - 2a}{5} =$ price of the pears; then $\frac{a}{6} + \frac{200 - 2a}{5} = 2\text{s. } 2\text{d.}$ $(= 26\text{d.})$ per queſtion. This Equation, multiplied by 30, we have $5a + 1200 - 12a = 780$. By tranſpoſition, $7a = 1200 - 780 = 420$, and by diviſion $a = 60$, the number of apples; and $100 - 60 = 40$, the number of pears.

QUEST. IV. It is required to divide the number 128 into four ſuch parts, that if the firſt be added to 7, the ſecond ſubtracted from 7, the third multiplied by 7, and the fourth divided by 7, the reſults may be equal among themſelves.

Let, v, x, y, and z, be the required parts. Then $v + 7, = x - 7, = 7y, = \frac{z}{7}$, per queſtion. And from the equality of the two firſt, $x = v + 14$; from the equality of the firſt and third, $y = \frac{v + 7}{7}$, and from the equality of the firſt and fourth $z = \overline{v + 7} \times 7 = 7v + 49$. Therefore (by collecting theſe together) $v + v + 14 + \frac{v + 7}{7} + 7v + 49 = 128$. By collecting the terms and tranſpoſition, $9v + \frac{v + 7}{7} = 65$; and by multiplying this by 7, collecting the terms, tranſpoſing, and dividing, $v = 7$; and hence $x = 7 + 14 = 21$; $y = \frac{7 + 7}{7} = 2$; and $z = \overline{7 + 7} \times 7 = 98$; the ſeveral parts required.

QUEST. V. There are two cubical pieces of marble, and the ſide of one, exceeds the ſide of the other, by three inches, and the ſolid inches in both are 2457 inches. Of what length is the ſide of each cubical piece?

Let the ſide of the leſs be x, then the ſide of the greater will be $x + 3$; and $x^3 + \overline{x + 3}^3 = 2547$ inches, per queſtion. Hence, $2x^3 + 9x^2 + 27x = 2430$. This Equation ſolved, $x = 9$, and conſequently $y = 12$.

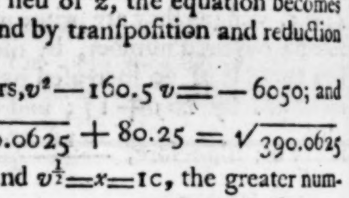
QUESTION VI. The ſum of two numbers multiplied by the greater is 110, and their difference multiplied by the leſs is 9, what are thoſe numbers?

Put $110 = a$, and $9 = b$, and let x and y be the two numbers, whereof x is the greater; then $\overline{x + y} \times x = x^2 + xy = a$; and $\overline{x - y} \times y = xy - y^2 = b$, per queſtion.

Again: Put $v = x^2$, and $z = y^2$; ſo will $v + \sqrt{vz} = a$, and $\sqrt{vz} - z = b$; and ſubtracting the latter Equation from the former, $v + z = a - b$; hence $z = a - b - v$; by tranſpoſing the former Equation, $\sqrt{vz} = a - v$, and ſquaring both ſides, $vz = a^2 - 2av + v^2$. Then by ſubſtituting $a - b - v$, in lieu of z, the equation becomes $av - bv - v^2 = a^2 - 2av + v^2$; and by tranſpoſition and reduction $v^2 - \frac{\overline{3a - b}}{2} \cdot v = -\frac{a^2}{2}$. In numbers, $v^2 - 160.5v = -6050$; and therefore, $v = \sqrt{-6050 + 6440.0625} + 80.25 = \sqrt{390.0625} + 80.25 = 19.75 + 80.25 = 100$, and $v^{\frac{1}{2}} = x = 10$, the greater number. $z = a - b - v = 110 - 9 - 100, = 1$; and therefore $z^{\frac{1}{2}} = 1 = y$ the leſs number.

N. B. This queſtion is the ſame as the ſecond in the *Gentleman's Diary* for the enſuing year (1789) only there the numbers a and b are taken larger.

QUESTION VII. Let the ſides of the triangle ABC be as follow; viz. AB=24, AC=28, and BC=18, it is required to find the ſegments of the baſe AD, and DC, made by a perdendicular let fall from B.



Take AE=DC, and divide AC into two equal parts as at O; then becauſe AE=DC, ED=the difference of the ſegments; and becauſe AO=OC, EO=OD=½ difference: alſo AO+OD=AD, the greater ſegment =OC+OD; and OC−OD=DC= leſs ſegment. Now put half difference of ſegments EO or OD$=x$, and let AB$=a$, BC$=b$, and AO or OC$=\frac{1}{2}$AC$=c$; ſo will $c + x =$ AD, and $c - x =$ DC. Then, by the Pythagorean Theorem (ſee GEOMETRY) $a^2 - \overline{c + x}^2$ $(= \text{BD}^2) = b^2 - \overline{c - x}^2$; and therefore, $a^2 - c^2 - 2cx - x^2 = b^2 - c^2 + 2cx - x^2$; viz. $a^2 = b^2 + 4cx$, or $a^2 - b^2 = 4cx$; or, which is the ſame, $\overline{a + b} \times \overline{a - b} = 4cx$. This reſolved into a proportion by (Art. 17.) we have as $2c : \overline{a + b} :: \overline{a - b} : 2x$; viz. as the baſe AC is to the ſum of the ſides AB and BC, ſo is the difference of thoſe ſides to ED, the difference of the ſegments of the baſe: a well-known theorem in Trigonometry. Or by taking $4c$ for the firſt term, and x for the laſt, it will be, as twice the baſe is to the ſum of the ſides; ſo is the difference thereof to half the difference of the ſegments.

Wherefore, in the preſent example, as (2AC) 56 : (AB+BC) 42 :: (AB−BC) 6 : $\frac{42 \times 6}{56} = \frac{21 \times 6}{8} = \frac{21 \times 3}{14} = \frac{3 \times 3}{2} = 4\frac{1}{2} =$ ½ difference of ſegments, then 14 (AO or OC) $+ 4\frac{1}{2} = 18\frac{1}{2} =$ AD, the greater ſegment; and $14 - 4\frac{1}{2} = 9\frac{1}{2} =$ DC, the leſs ſegment.

N. B. The greater ſegment is always adjacent to the greater remaining ſide, and the leſs ſegment is adjacent to the leſs remaining ſide.

QUEST.

ALGEBRA.

Quest. VIII. Having a conical veſſel full of liquor ſtanding upon its leſs end, the radius of which is 20 inches, into which I immerſed a cone of equal baſe and altitude, the convex ſurface whereof is 2827.44, and is equal to the area of the top of the veſſel. Required its content and the quantity of liquor in ale gallons that overflowed by ſo doing. Let the top diameter of the veſſel be x, and its height y, = alſo the height of the cone; and let $20 = a$, and $2827.44 = b$. Alſo put $.7854 = p$, then $px^2 = b$, per queſtion, and therefore $x^2 = \frac{b}{p}$. But the reciprocal of $\frac{1}{p} = 1.27324$, and therefore $x^2 = 1.27324 \times b = 3600$; and $x = \sqrt{3600} = 60$ inches, the top diameter of the veſſel.

Alſo (per Menſuration) $\sqrt{\frac{a^2}{4} + y^2}$ = the ſlant ſide of the cone, and $2pa \times \sqrt{\frac{a^2}{4} + y^2}$ = convex ſurface of the cone $= b$; therefore $\sqrt{\frac{a^2}{4} + y^2} = \frac{b}{2pa}$; and $\frac{a^2}{4} + y^2 = \frac{b^2}{4p^2a^2}$, and conſequently $y^2 = \frac{b^2}{4p^2a^2} - \frac{a^2}{4}$. and $y = \sqrt{\frac{b^2}{4p^2a^2} - \frac{a^2}{4}} = \sqrt{4996.51 \times \overline{1.27324}|^2} = \sqrt{4996.51 \times 1.62114} = \sqrt{8100.} = 90$, the height of the veſſel, and altitude of the cone.

Then $\overline{20 \times 60 + 20^2 + 60^2} \times \frac{90}{3} \times .7854 = 207345.6$ cubic inches, the content of the veſſel = 735,27 ale gallons. And $\overline{20}^2 \times 30 \times .7854 = 9424.8$ cubic inches, the content of the cone, = 33.42 ale gallons, which overflowed by its immerſion.

N. B. This is the 4th queſtion in the *Ladies' Diary*, for the enſuing year, (1789.)

Question IX. Given the cuve ſurface of the ſegment of a ſphere = 1600, and the difference between its ſolid content and that of a cylinder of the ſame diameter and altitude, = 1800; to determine both the diameter and altitude. Let. $z = \frac{1}{2}$ the diameter, and x = the altitude, and let $.7854 = p$. Then $\overline{z^2 + x^2} \times 4p$ = the curve ſurface of the ſegment, = 1600 (per queſtion.) And $z^2 + x^2 = \frac{400}{p}$. Alſo, $\overline{3z^2 + x^2} \times \frac{2px}{3}$ = its ſolidity; and $4pz^2x$ = the ſolidity of the cylinder. (vide menſuration). Therefore $\overline{3z^2 + x^2} \times \frac{2px}{3} - 4pxz^2 = 1800$ (per queſtion). Divide by $\frac{2p}{3}$, and $3z^2x + x^3 - 6xz^2 = 1800 \times \frac{3}{2p} = \frac{2700}{p}$; or $x^3 - 3xz^2 = \frac{2700}{p}$.

Now from the Equation above, viz. $z^2 + x^2 = \frac{400}{p}$, we have $z^2 = \frac{400}{p}, - x^2$, which ſubſtituted in this laſt Equation, there is $x^3 - \frac{1200x}{p} + 3x^3 = \frac{2700}{p}$, or (by reduction) $x^3 - \frac{300x}{p} = \frac{675}{p}$. The reciprocal of $\frac{1}{p} = 1.27324$. Therefore the Equation is $x^3 - 300 \times 1.27324x = 675 \times 1.27324$; or $x^3 - 381.972x = 859.437$, which cubic Equation, ſolved, $x = 20.584548$ inches the altitude, and $z^2 = \frac{400}{p} - x^2 = 400 \times 1.27324 - {}^2x = 509.296 - 423.723616$, &c. $= 85.572384$, &c. and $z = \sqrt{85.572384}$, &c. $= 9.250534$, and $2z = 18.501068$, inches the required diameter.

N. B. This is the 6th queſtion in the Ladies Diary for the next year 1789.

Quest. X. There is a cubical block of marble, whoſe ſide in inches is expreſſed by two digits; the ſuperficies of the block is equal to 864 times the ſum of the ſaid digits; and its ſolidity is equal to 576 times the ſquare of the ſum of the ſaid digits: required the dimenſions.

Let x = the digit in the tens place, and y = the digit in the place of units, then $10x + y$ = ſide of the cube, and $\overline{10x + y}|^2 \times 6 = 864 \times \overline{x + y}$; or $\overline{10x + y}^2 = 144 \times \overline{x + y}$. Alſo, $\overline{10x + y}^3 = 576 \times \overline{x + y}^2$ per queſtion; and multiplying theſe Equations croſswiſe, $\overline{10x + y}^2 \times 576 \times \overline{x + y}^2 = 144 \times \overline{x + y} \times \overline{10x + y}|^3$ Now, dividing both ſides by $144 \times \overline{x + y} \times \overline{10x + y}^2$, we have $\overline{x + y} \times 4 = 10x + y$, or $x4 + 4y = 10x + y$, and by tranſpoſition $3y = 6x$, and therefore $y = 2x$. This being ſubſtituted for y in the former Equation ($\overline{10x + y}^2 = 144 \times \overline{x + y}$) there is $\overline{10x + 2x}|^2 = 144 \times \overline{x + 2x}$, or $144x^2 = 144 \times 3x$, and dividing by $144x$, we have $x = 3$, and $y = 2x$ 6; and therefore the ſide of the cube is 36.

N: B. This is the 10th queſtion in the *Ladies' Diary* for next year.

Quest. XI. On what day in the following year (1789) will the ſun's right aſcenſion be equal to the complement of his declination, the obliquity of the ecliptic being 23° 28'?

Let radius = 1, and the co-tangent of 23° 28' $= 2.3035064 = a$; alſo put z = tangent of the declination. Then (per Trigonometry) $\frac{1}{\sqrt{1 + z^2}}$ = coſine of the declination = ſine of the right aſcenſion: But (per Aſtronomy) as $1 : a :: z : az$ = ſine of right aſcenſion. Therefore $az = \frac{1}{\sqrt{1 + z^2}}$ and $a^2z^2 = \frac{1}{1 + z^2}$; by Multiplication, $a^2 = z^2 + a^2z^4 = 1$; and by diviſion $z^4 + z^2 = \frac{1}{a^2}$. Hence, (putting $x = z^2$) $x = \sqrt{\frac{1}{a^2} + \frac{1}{4}}| - \frac{1}{2} = \sqrt{\frac{a^2 + 4}{4a^2}} = \frac{1}{2} = \frac{1}{2a}\sqrt{a^2 + 4} - \frac{1}{2}$; = (by reſtoring the value of a, and extracting the root, &c.) .1622811; and $\sqrt{x} = z = \sqrt{.1622811} = .4028413$ = tangent 21° 56'½, the ſun's declination, which, from the nature of the queſtion, muſt be north increaſing; and therefore it is anſwerable to the 31ſt of May, when the ſun's right aſcenſion will be equal to the complement of his declination.

Quest. XII. It is required to find a ſeries of whole numbers, each term of which being divided by 14, ſhall leave a remainder of 4; divided by 50, ſhall leave a remainder of 30; divided by 85, ſhall leave a remainder of 45; and alſo each term divided by 95, ſhall leave a remainder of 85; by a general method which may be applied to the ſolution of any other queſtion of the like nature. This is the Prize Queſtion in the *Gentleman's Diary* for the enſuing year; to ſolve which, we ſhall firſt proceed to find the leaſt term in the ſeries.

Let x = the quotient, when divided by 14. Then $14x + 4$ = the required number. Alſo $\frac{14x + 4 - 30}{50}$ = a whole number per queſtion $= \frac{7x - 13}{25}$; now the leaſt value of y by the lemma delivered in Art. 31 is 9; which ſubſtituted in the above expreſſion $(14x + 4)$ we have 130, which is the leaſt number that will anſwer the firſt two conditions.

Now it is plain, that the number which will anſwer three of the conditions, muſt be ſuch a one as will divide by 14 and 50, without a remainder, +130. The leaſt number that will do this is 350, (ſee ſection of Fractions in our new Syſtem of Arithmetic). But as it may be ſome multiple thereof, let z be the multiple; ſo will $350z + 130$ be the number; and $\frac{350z + 130 - 45}{85}$ = a whole number per queſtion; $= \frac{70z + 17}{17} = 4z + 1 + \frac{2z}{17}$; and therefore $\frac{2z}{17}$ = a whole number; and becauſe 2 and 17 are prime to each other, the leaſt whole number for z is 17; this ſubſtituted in the foregoing expreſſion $(350z + 130)$ it makes $5950 + 130 = 6080$, which is the leaſt number that will anſwer three of the conditions.

Now the number that will anſwer all the conditions muſt be the ſum of this number and ſome other that will divide both by 350, and 85, without a remainder. The leaſt number that will do this $= 350 \times 17 = 5950$; but as it may be ſome multiple thereof, let $5950y + 6080$ = the required number; and then $\frac{5950y + 6080 - 85}{95}$ = a whole number per queſtion, $= \frac{1190y + 1199}{19} = 62y + 63 + \frac{12y + 2}{19}$. Therefore $\frac{12y + 2}{19}$ = a whole number; and the leaſt value of y, by the ſaid lemma, is 3, which ſubſtituted for y, we have the value of the leaſt number in the required ſeries $= 17850 + 6080 = 23930$. Furthermore the leaſt number that will divide by 5950, and 95 without a remainder $= 5950 \times 19 = 113050$; by the continual addition of which, an Arithmetical ſeries will be formed, exhibiting all the poſſible numbers that will ſatisfy the enquiry. Thus 23930, 136980, 250030, 363080, 476130, &c. *ad infinitum*, will, ſeverally, if divided by the propoſed numbers, 14, 50, 85, and 95, leave the given remainders 4. 30, 45, and 85, reſpectively. There are other ways of coming at the ſame thing; but I know of none, ſo *clear*, ſo *general*, and withal ſo *eaſy*.

What has been digeſted in this ſyſtem is amply ſufficient to initiate any one of a mathematical genius into the method of Algebraical operations, as well as to ſhew the extenſiveneſs of the art in cultivating and improving different branches of ſcience; for there is not a ſubject within the reach of human contemplation, but it may be applied to it with ſucceſs, provided the firſt principles thereof are comprehended in the mind.

ALGEBRA.

As our ultimate end is to lay before the public a complete repoſitory of uſeful and ſcientific knowledge, and as we would only wiſh to eſtabliſh our reputation upon the due claims of merit, we are determined that nothing ſhall be wanting, either of expence or pains, to give the work a diſtinguiſhed pre-eminence over the paultry and vague performances of our puſillanimous competitors.

In this Syſtem I have purpoſely omitted certain articles which are to be met with in ſome books of Algebra, apprehending that they may be introduced with greater propriety under other heads. Such are, the methods of ſumming and reverting Infinite Series *and Queſtions of the* Maxima *and* Minima, *which I ſhall treat of in the Doctrine of* Fluxions *and Method of* Increments; *alſo* Figurate *and* Poligonal Numbers, *&c. which will come in order in the New Syſtem of* Arithmetic; *and as Mr.* Cooke *has placed confidence in my abilities, and engaged me to undertake ſuch parts of the Work as are connected with the Mathematics; I pledge the honour of my reputation, both to him and the public, that, in thoſe matters, the* New Royal Encyclopædia *ſhall excel every other* Dictionary of Arts and Sciences *that has yet been publiſhed.*

ROBERT MOODY.

ALGEBRAICAL, ſomething that relates to Algebra; as an Algebraical Curve denotes a curve wherein the relation of the abſciſſes to the ſemidiordinates may be defined by an Algebraical Equation. Theſe are alſo called geometrical lines; and ſtand contradiſtinguiſhed to mechanical or tranſcendental ones.

ALGEBRAISM, implies the application of Algebra; but is ſeldom uſed in this ſenſe, unleſs affectedly to ſignify an abſtruſe ſubject.

ALGEBRAIST, a perſon ſkilled in the ſcience of Algebra.

ALGEDO, implies an accident which ſometimes happens in a gonorrhœa, by ſtopping the diſcharge too ſoon; the ſymptoms of which are pains in the lower extremities, and a bearing down of the body in ſtools. The only remedy in this caſe, ℞, about two grains of prepared calomel abſorbed on the tongue, which will purge the patient and bring back the running, ſo that all danger and difficulties will diſappear. It is to be remarked that the ſafeſt and beſt mode in this ſtage, is to take the calomel, an hour before breakfaſt in the morning during the ſummer ſeaſon; but in the autumn, winter or ſpring, it will be beſt an hour after ſupper.

For further particulars on the general treatment of this diſeaſe, ſee Syſtem of Surgery.

ALGENEB, or Algenib, in aſtronomical obſervations, implies a fixed ſtar of the ſecond magnitude on the right ſide of the Conſ. Perſeus. Long. 27° 46′ 12″ of ♉, Lat. 30° 5′ 28″ N.

ALGIABARII, a Mahometan ſect of predeſtinarians, who impiouſly attribute good and evil to flow promiſcuouſly and ſpontaneouſly from the Deity.

ALGOIDES, in botany, implies a ſynonomy of zannichellia.

ALGOL, commonly called Meduſa's head, a name given to a fixed ſtar of the third magnitude in Perſeus. Long. 21° 50′ 42″ of ♉, Lat. 23° 23′ 47″ N.

ALGONQUIN, a technical word, implying one of the chief languages of the native Indians in North America, contradiſtinguiſhed from the other principal tongue called the Hûron.

ALGOR, in medical language, denotes a particular coldneſs of any member of the body, which indicates a dangerous ſymptom.

ALGORAB, a fixed ſtar of the third magnitude, ſituated on the right wing of the conſtellation Corvus.

ALGORITHM, ſignifies the fundamental rules of Arithmetic; i. e. numeration, addition, ſubtraction, multiplication and diviſion. The word is derived from the Arabic, *algoraf*, to number.

ALGOSAREL, an obſolete ſynonyme in botany, for the daucus ſylveſtris, or wild carrot.

ALGUAZIL, a name given to the repreſentative of a Spaniſh judge, who preſides over decretal orders of magiſtracy.

ALHABOR, a name given by the Arabian aſtronomers to the ſtar, which we generally call Sirius.

ALHAGI, a ſpecies of thorny broom, which grows in Syria; from this plant the natives gather a new ſort of manna. The leaves are aſtringent, but the flowers are laxative.

ALHANDAL, implies colocynth, in the Arabian pharmacy.

ALHEN, a ſynonyme in botany, of the lawſonia of Linnæus.

ADHIDADE, or Alidade, the index of an inſtrument uſed in alimetry or longimetry.

ALHIRTO, in aſtronomy, ſignifies a fixed ſtar of the 3d magnitude, placed in the conſtellation Capricorn, or 10th ſign of the zodiac; ſometimes called the roſtrum gallinæ.

ALI, gives the denomination to a ſect, or diviſion, among the Mahometans, who adhere to the right of ſucceſſion of Ali the fourthcaliph or ſucceſſor of Mahomet, and to the reform of Muſſulmaniſm introduced by him.

The ſectaries of Ali are more particularly called Schiites; and ſtand oppoſed to the Sunnites, or ſect of Omar, who adhere to the law as left by Mahomet, Abubeker, and Omar.

Ali was couſin of Mahomet, and ſon-in-law of that prophet, having married his daughter Fatimah. After Mahomet's death, great diſputes aroſe about the ſucceſſion. Many ſtood for Ali; but Abubeker was preferred, and elected the firſt kalif. Ali took his turn, after the death of Othman.

The Perſians are the chief adherents to the ſect of Ali, whom they hold to have been the legitimate ſucceſſor of Mahomet, and Abubeker an uſurper.

On the contrary, the Turks are of the ſect of Omar; and hold Ali in execration, having raiſed a furious civil war among the Muſſulmans.

The diſtinguiſhing badge of the followers of Ali is a red turban, which is worn by the Perſians, who are hence called in deriſion, by the Turks, kiſilbachi, q. d. red-heads.

Ali is reputed the author of ſeveral works, part of which has been publiſhed in Engliſh by Mr. Ockley.

ALJAMEIA is a name which the Moriſcoes in Spain give to the language of the Spaniards. Among other articles agreed on by the junto, which was appointed by the emperor Charles V. in 1526, in favour of the Moriſcoes, this was one, that the Moriſcoes ſhould no longer ſpeak Algavareia, i. e. Mooriſh or Arabic; but ſhould all ſpeak Aljameia, i. e. Spaniſh, as it was called by the Moors, and all their writings and contracts ſhould be in that language.

ALIARBUCHA, in zoology, implies a ſpecies of the mus kind, about the ſize of a Norway rat, and eaten by the modern Arabs, with as good reliſh as the Europeans do the rabbit.

ALIAS, in law, a ſecond or farther writ iſſued from the courts of Weſtminſter, after a capias, &c. ſued out without effect.

ALIBI, in law, denotes the abſence of the accuſed from the place where he is charged with having committed a crime; or his being elſewhere, as the word imports, at the time ſpecified.

ALICA, a name given to gruel made of grots, or oatmeal cutlings. A phraſe which has been criticiſed to very little purpoſe; unleſs to the manifeſt ridicule of the critic.

ALICARIÆ, in antiquity, implies common proſtitutes.

ALICATA *Chlamys*, or Alicula, was a ſort of veil with ſleeves, worn by the Roman boys till the age of thirteen, at which time they put on the prætexta.

ALICATICA, an Arabian weight, anſwering to about four ounces.

ALICES, in medicine, imply the ſpots preceding the ſmall pox, which are generally red under the ſkin, and rough previous to the irriguous excreſſences or irruptions.

ALIDES imply the ſectariſts in the Mahometan religion, who hold the tenets of their religion from the doctrine of Ali, the ſon-in-law of the prophet; which the Turks in ridicule call Fatimites, from Fatima, the daughter of the prophet, and wiſe of the legiſlator.

ALIE KRUYK, a name given by Swammerdam to the ſea ſnail.

ALIEN, in law, implies a perſon born in a ſtrange country not within the king's allegiance; in contradiſtinction to a denizen, or natural ſubject. The word is formed from the Latin *alius*, "another"; q. d. one born in another country.

An alien is incapable of inheriting lands in Britain till naturalized by an act of parliament.

No alien is intitled to vote at the election of members of parliament; nor can he enjoy any office, or be returned on any jury, unleſs where an alien is partly in a cauſe, when the inqueſt is compoſed of an equal number of denizens and aliens.

It is to be underſtood nevertheleſs, that all thoſe who are born in the king's dominions are not aliens but denizens, ſo that the children of foreigners born here are natural born ſubjects.

Alſo it is to be remarked that the children of natural born ſubjects, although they were born under the controul or in the dominions of a foreign power, yet they have a right to the privileges and protection of the king of Great Britain as his ſubjects, as much ſo as if they were born in his dominions; for in the eye of the law they are actually bona fide ſubjects of the Imperial crown of this realm.

Among the Romans, only the Cives Romani were eſteemed freemen; but when their territories increaſed, all the Italians were made free, under the name of Latins, though they had not the privilege of wearing gold rings till the time of Juſtinian. Afterwards all born within the pale of the empire were conſidered as citizens.

Alien *Duty*, an impoſt laid on all goods imported by aliens, over and above the cuſtoms paid for ſuch goods imported by Britiſh, and on Britiſh bottoms.

Aliens *Duty* is otherwiſe called petty cuſtoms, and navigation duty. Fiſh dried or ſalted, and cod-fiſh or herring not caught in Britiſh veſſels and dured by Britiſh, pay a double aliens-duty.

ALIEN *Priories*, denoted a kind of inferior monaſteries, formerly very numerous in England, and ſo called from their belonging to foreign abbeys.

ALIENATION, in law, denotes the act of making over a man's property in land, tenements, &c. to another perſon.

ALIENATION, in mortmain, implies the making over lands, tenements, &c. to a body-politic, or to a religious houſe, for which the king's licence muſt firſt be obtained, otherwiſe the lands, &c. alienated, will be forfeited to the crown.

ALIENATION, in fee, is the ſelling the fee-ſimple of any land, or other incorporeal right.

All perſons who have a right to lands may generally alien them to others; but ſome alienations are prohibited: ſuch as alienations by tenants for life, &c. whereby they incur a forfeiture of their eſtate. By the ſtatute of Edward I. a bar was put to alienations by what we call entails, which is an expedient for procuring perpetuities in families; but counter expedients were deviſed to defeat this intent, and a practice was introduced of cutting off entails by fines, and of barring remainders and reverſions by recoveries.

The ſtatute for alienations in Henry VII.'s time had a great effect on the conſtitution of this kingdom; as, among other regulations of that reign, it tended to throw the balance of power more into the hands of the people.

By the ſtat. 12 Car. II. cap. 24. fines for alienations are taken away. Crown lands are only alienable under a faculty of perpetual redemption. The council of Lateran, held in 1123, forbade any clerk to alienate his benefice, &c.

By the laws of the ancient Jews, lands could only be alienated for the ſpace of 50 years. At each return of the jubilee all returned again to the primative owners, or their deſcendants, to whom the lands were originally allotted at the firſt diſtribution of Canaan.

ALIENATION *Office*, is an office to which all writs of covenants and entry, upon which fines are levied, and recoveries ſuffered, are carried, to have fines for alienation ſet down and paid thereon.

ALIFORMES, or ALIFORMIS MUSCULIS, in anatomy, implies the name of a pair of muſcles ariſing from the prerygoid bone, and ending in the neck of the lower jaw, towards the internal ſeed of the head. See Syſtem of ANATOMY, under the article MUSCLE.

ALIFORMES, or ALIFORMIS PROCESSUS, in anatomy, ſignifies the *os cuneiforme*.

ALII MULTI, ALII DE REGNO, in antiquity, imply the commonalty of that part of Great Britain called England.

ALIMA, in mineralogy, ſignifies a ſandy lead ore.

ALIMENT implies food both ſolid and liquid; from which, by the proceſs of digeſtion, is prepared a very mild, ſweet, and whitiſh liquor, reſembling milk, and diſtinguiſhed by the name of chyle; which being abſorbed by the lacteal veins, by them conveyed into the circulation, and there aſſimilated into the nature of blood, affords that ſupply of nutrition which the continual waſte of the body is found to require.

Next to air, food is the moſt neceſſary thing for the preſervation of our bodies; and as on the choice thereof our health greatly depends, it is of material importance to underſtand, in general, what is the moſt proper for our nouriſhment; and, in particular deviations from health, what is the beſt adapted to reſtore us.

Our blood and juices naturally incline to become putrid and acrimonious: freſh chyle, duly received, prevents this deſtructive tendency, and preſerves in them that mild ſtate which alone conſiſts with health.

An animal diet affords the moſt of this mild nutritious mucilage; watery fluids dilute the too groſs parts, and carry off what is become unfit for uſe. It is only the ſmall portion of jelly which is ſeparated from the farinaceous parts of vegetables, that, after being much elaborated, is converted into the animal nature; yet the uſe of vegetables prevents both repletion and a too great tendency to a putreſcent acrimony of the blood.

In hot climates, as well as againſt the conſtitutional heat of particular perſons, vegetables are neceſſary in the largeſt portion.

Animal ſubſtances afford the higheſt reliſh while our appetites continue; but will ſatiate the appetite before the ſtomach is duly filled.

Vegetables may be eaten after either fleſh or fiſh: few herbs or fruits ſatiate ſo much as that the ſtomach may not be filled with them, when it is already ſatisfied with fleſh or fiſh; whence it may be obſerved, that no diet which is very nouriſhing can be eat to fulneſs, becauſe its nutritious parts are oily and ſatiating.

Health depends almoſt wholly on a proper craſis of the blood; and to preſerve this a mixture of vegetables is always required; for a loathing is ſoon the conſequence of animal food alone: hot acrid habits, likewiſe, receive from milk and vegetables the needful for correcting their exceſſes; but in cold, pituitous, and nervous habits, which want moſt nouriſhment from leaſt digeſtion, and from the ſmalleſt quantity of food, animal diet is to be uſed more freely.

In winter a healthy perſon may eat freely, but drink ſparingly: roaſt meat is to be preferred, and what is drank ſhould be ſtronger than at other ſeaſons.

In ſummer, let thirſt determine the quantity to be drank; cold ſtomachs never require much: boiled meats and vegetables, if not otherwiſe contradicted, may now be more freely uſed.

Lax habits require the winter's diet to be continued all the year, and rigid ones ſhould be confined to that of ſummer.

Thoſe who are troubled with eructations occaſioned by their food ſhould drink but little, and uſe moderate exerciſe.

The thirſty ſhould drink freely, but eat ſparingly.

In general, moderation ſhould be obſerved. After very high-ſeaſoned meats, a glaſs of water acidulated with the acid elixir of vitriol, or in very weak ſtomachs, the ſweet elixir of vitriol is far more aſſiſtant to the work of digeſtion than the common method of taking ſpirituous liquors.

ALIMENTARII PUERI, in the Roman code, implied certain children maintained and educated by the munificence of the emperors, in a ſort of public places, not unlike our hoſpitals. Trajan was the firſt who brought up any of theſe alimentary boys. He was imitated by Adrian. Antoninus Pius did the ſame for a number of maids, at the ſolicitation of Fauſtina; and hence, in ſome medals of that empreſs, we read PVELLAE FAVSTINIANAE. Alexander Severus did the like at the requeſt of Mammæa; and the maids thus educated were called Mammæanæ.

ALIMENTARY, an epithet applied to every thing relating to aliment or food.

ALIMENTARY DUCT, a ſynonyme of the Thoraic Duct.

ALIMENTARY DUCT, or CANAL, is a name given by Dr. Tyſon and ſome others to that part of the body through which the food paſſes, from its reception into the mouth to its exit at the anus; including the gula, ſtomach and inteſtines.

This duct has been ſaid to be the true characteriſtic of an animal, or *in proprium quarto modo*; there being no animal without it, and whatever has its being properly enough ranged under the claſs of animals. Plants receive their nouriſhment by the numerous fibres of their roots, but have no common receptacle for digeſting the food received, or for carrying off the recrements. But in all, even the loweſt degree of animal life, we may obſerve a ſtomach and inteſtines, even where we cannot perceive the leaſt formation of any organ of the ſenſes, unleſs that common one of feeling, as in oyſters. Phil. Tranſ. Nº 269, p. 776, ſeq.

Dr. Wallis brings an argument from the ſtructure of the alimentary tube in man, to prove that he is not naturally carnivorous, to which Dr. Tyſon makes ſome objections. See Phil. Tranſ. Nº 269, p. 777.

ALIMENTARY LAW, *lex alimentaria*, was an old law among the Romans, whereby children were obliged to find ſuſtenance for their parents.

ALIMENTATION, an epithet which implies nutrition, and may be properly called a ſynonyme of that word.

ALIMONY, in law, implies that allowance which a married woman ſues for, and is intitled to, upon any occaſional ſeparation from her huſband.

ALIMOS, a Greek botanic name for the common liquoriſh, or liquorice.

ALINDESIS, αλινδος, in antiquity, implies an oily ſubſtance with which gymnaſtic exerciſers were wont to beſmear their ſkin, and then roll themſelves in the duſt to harden their fleſh, and to cloſe up the pores of their ſkin, ſo that they were ſecure from bruiſes either by falls or blows.

ALIOS, in ichthyology, a ſynonime of the Lophius and Ranus, or Rana piſcatrix.

ALIPÆNOS, in the medicine of the ancients, implied a topical remedy freed from oily juices or fatneſs. Galen calls it αλιπη, which was uſually applied to freſh wounds to prevent inflammation, at the ſame time heal up the orifice.

ALIPILARIUS, or ALIPILUS, in Roman antiquity, a ſervant belonging to the baths, whoſe buſineſs it was, by means of waxen plaſters, and an inſtrument called volſella, to take off the hairs from the arm-pits, and even arms, legs, &c. this being deemed a point of cleanlineſs.

ALIPTERIUM, in antiquity, a place in the ancient paleſtræ, where the athletæ were anointed before their exerciſes.

ALIQUANT PART, in arithmetic, is that number which cannot meaſure any other exactly without ſome remainder. Thus 7 is an aliquant part of 16; for twice 7 wants two of 16, and three times 7 exceeds 16 by 5.

ALIQUOT PART, is that part of a number or quantity which will exactly meaſure it without any remainder. Thus 2 is an aliquot part of 4; 3 of 9; 4 of 16, &c.

ALISANDERS, or ALEXANDERS, in botany, a ſynonyme of SMYRNIUM.

ALISMA, or WATER-PLANTAIN, a genus of the polygynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 5th order tetrapetaloideæ. For the characters, ſee Syſtem of BOTANY.

Of this genus there are eight ſpecies, viz. The plantago, or great water-plantain, which grows in all the marſhy parts of this country; the ranunculoides, or leſſer water-plantain; the natans, or creeping water-plantain; the damaſonium, or ſtar-headed water-plantain; all which are natives of Britain. The flava, cordifolia, ſubulata, and parnaſſifolia, are natives of America, where they are generally found in ſtagnating waters, and other ſwampy places.

ALITES, in Roman antiquity, a deſignation given to ſuch birds as afforded matter of augury by their flight.

ALKA, in ornithology, is a water-fowl of the diver kind belonging to the order of anſeres in the Linnæan ſyſtem, which is the ſame as that bird well known in England under the denomination of the razor bill.

ALKAHEST, or Alcaheſt, in alchemy, an univerſal menſtruum capable of reſolving all bodies into their firſt principles.

ALKAHESTIC, implies a body which is powerfully ſolvent, and may be taken as a ſynonyme of menſtruous, or menſtruum, with this difference; that the latter imports a leſs ſolutive power than the former.

ALKALESCENT, denotes a matter ſlightly alkaline, or which begins to turn to the alkaline and putrid fermentation.

ALKALI, or Alkaly, in chemiſtry, one of the general diviſions of ſalts, comprehending that claſs of chemical elements which, by their union with acids, form perfect neutrals, in oppoſition to the ſalts formed of acids with metals or earths, which are called imperfect ſalts.

Alkaline ſalts are divided into two kinds, viz. the fixed and the volatile; the former into two ſpecies, vegetable and mineral. All of theſe poſſeſs ſome properties in common, yet moſt of them have peculiar qualities of themſelves.

Thoſe which they have in common are, 1. An acrid and pungent taſte, which, when the ſalts are very pure and ſtrong, degenerates into abſolute cauſticity, and would entirely deſtroy the organ of ſenſation if long applied to it. 2. A tendency to diſſolve animal ſubſtances, and reduce them to a gelatinous ſubſtance, which all of them will do when very ſtrong. 3. An attraction for acids, with a power of ſeparating earths and metals from them, though previouſly combined with the ſame. 4. They change the blue vegetable juices to green; the green to yellow; the yellow to orange; the orange to red; and the red to purple. 5. They unite with oils, and deſtroy, or cauſe to fade, almoſt all kinds of colours that can be put upon cloth, whence their uſe in bleaching, clearing, &c.

The properties common to both kinds of fixed alkalies are, 1. They reſiſt the action of fire to a great degree, ſo that they can eaſily be reduced to a ſolid form by evaporating any liquid in ſhhich they happen to be diſſolved. 2. By an intenſe fire, they flow into a liquid which concretes into an hard and ſolid maſs in the cold. 3. When mixed in certain proportions with thoſe earths or ſtones called vitrifiable, they melt in a heat ſtill more intenſe, into glaſs. 5. Mixed with ammonical ſalts, with animal ſubſtances, or with ſoot, they extricate a volatile alkali.

The volatile alkali differs from the other two in being unable to reſiſt the fire, and being entirely reſolvable into an inviſible and permanently elaſtic fluid, called alkaline air.

In conſequence of this volatility, it always affects the olfactory nerves very perceptibly, and its ſmell is the general criterion by which its ſtrength may be judged of. Its attraction for acids, power of changing colours, &c. are alſo conſiderably weaker than thoſe of the fixed alkalies.

Though two ſorts of volatile alkali are commonly ſold under the names of ſpirits of hartſhorn and of ſal ammoniac, the one differs from the other only in its degree of purity. The former is ſo called from its being originally made from the horns of deer; but this material has long been laid aſide, and the bones of horſes, the flints, as they are called, of the horns of cattle, the parings of hoofs, &c. have been ſubſtituted in their ſtead. This kind, however carefully prepared, always contains a portion of animal oil, the ſmell of which is very perceptible; the other, prepared from pure ſal ammoniac, is totally free of any empyreumatic ſmell, and is as pure as it can be obtained by any means whatever; therefore ſhould be always preferred to the former.

Efferveſcence with acids was formerly ſuppoſed to be a diſtinguiſhing property of alkalies, though it was always known that by a mixture with quick lime they might be deprived of this property. However, it has been ſhown, that the efferveſcing with acids is no property of pure alkali, but is occaſioned only by the eſcape of fixed air from it: of conſequence, when quick lime is added, which attracts the whole or greateſt part of the fixed air, no efferveſcence can be perceived.

In the ſtate in which the fixed alkalies are commonly met with, indeed, efferveſcence with acids may be ſaid to be an eſſential property; but this is entirely owing to the cauſe juſt mentioned, viz. a quantity of fixed air, to which they are united during the proceſs by which they were originally formed. The quantity of this air, however, is never ſo great as to ſaturate them entirely; on the contrary, their alkaline properties are always very perceptible, and they are commonly ſaid to be in a mild ſtate. But the truth is, that now they are in a kind of intermediate ſtate between what may be called perfectly mild and perfectly cauſtic. In their perfectly mild ſtate, they are united with ſuch a large quantity of fixed air as entirely overpowers their alkaline properties; and therefore they are no more entitled to the name of alkalies in this ſtate, than when combined with the marine, nitrous, or any other acid; in which caſe the compounds are called neutral ſalts. But it is a much more laborious and tedious proceſs to ſaturate an alkali completely with fixed air than with any other acid; nor does it very eaſily retain the aerial acid after it has once been combined with it. Hence the cauſtic taſte and properties of the alkali almoſt always predominate, and the ſalt contains a portion of pure and cauſtic alkali, to which alone its virtues are to be aſcribed.

Vegetable alkali is obtained in its greateſt purity by deflagrating nitre with charcoal, provided we make uſe of no more of the latter than is barely ſufficient to deſtroy the nitrous acid. It is, however, a very difficult matter to adjuſt this proportion with ſufficient accuracy; for if we employ too much charcoal, the ſalt will be conſiderably phlogiſticated; if too little, ſome part of the nitre will remain undecompoſed. Burnt tartar, therefore, purified by ſolution and filtration, may be looked upon as the beſt alkali we have.

The common alkalies, or aſhes as they are called, and ſaid to be obtained from the aſhes of vegetables, are always mixed with much phlogiſton, and ſometimes with lime, ſalt, or other hetorogeneous matter; for which reaſon they are not to be employed in the nicer chemical experiments, without being purified by ſolution in water, by filtration, and cryſtallization. The pureſt of all theſe ſalts is that called the blue pearl, which is imported from Hungary.

The vegetable alkali when thus purified, and containing near one half its weight of fixed air, is of a white colour when dry, with a very hot and cauſtic taſte, poſſeſſing, in an eminent degree, all thoſe qualities which have been aſcribed to the alkaline ſalts in general. It runs *per deliquium* when expoſed to the air; and is uſually incapable of being chryſtallized, though it acquires this property after being employed in the rectification of ardent ſpirit. It adheres more cloſely to acids than any ſubſtance hitherto diſcovered; though, from ſome experiments, Bergman was induced to believe that pure terra ponderoſa attracted acids ſtill more powerfully. But this has been diſcovered to be a miſtake by Dr. Withering, who, in a paper publiſhed in the 74th volume of the Philoſophical Tranſactions, ſhows, that unleſs where the earth is united with vitriolic acid, not only the vegetable, the foſſil, but even the volatile alkali in its pure or cauſtic ſtate, will ſeparate it from any other with which it may be combined. Terra ponderoſa, therefore, will always decompoſe vitriolated tartar, Glauber's ſalt, or vitriolic ammoniac; whence the miſtake of this celebrated chemiſt probably has proceeded. After this alkali has been once united with marine acid, it appears to have undergone ſome change; for the ſalt then produced, by combining it with the vitriolic acid, reſembles Glauber's ſalt almoſt as much as it does vitriolated tartar. It ſeems, therefore, to have made ſome approach towards the nature of foſſil alkali; but chemiſts have not enquired what would be the conſequence of repeated combinations of this kind.

The foſſil alkali differs from the vegetable in having a ſmaller attraction for acids, in being more eaſily fuſible by itſelf, and forming a more ſoluble compound with the vitriolic acid. It is alſo eaſily cryſtallizable, even without the addition of more fixed air than it naturally contains: and experience has determined it to be more proper for glaſs or ſoap manufactures than the vegetable alkali.

The foſſil, or mineral alkali, was antiently called natron or nitre, and is ſpoken of by Pliny and Tacitus as an ingredient in glaſs, &c. and the Scriptures inform us that it was uſed in baths. The knowledge of this ſalt was loſt in the general obſcuration of ſcience which took place on the decline of the Roman empire; nor do we find it mentioned till the time of the Hon. Mr. Boyle; and, even ſince that time, though M. du Hamel gave an accurate account of it in a Memoir for the year 1736, little farther notice was taken of it till within theſe laſt twelve years.

We are now certainly informed that the mineral alkali is found a native in many parts of the world, which never is the caſe with the vegetable alkali. The places where it abounds moſt are, Egypt, the country of Tripoli in Barbary, the peak of Teneriffe in one of the Canary Iſlands, Hungary, ſeveral of the provinces of Ruſſia, ſome parts of Aſia, particularly the neighbourhood of Smyrna, &c. though it has not hitherto been found in any of the Weſtern countries of Europe, excepting in the neighbourhood of volcanoes, or in mineral waters; and in theſe laſt only in very ſmall quantities.

The great ſource of the mineral alkali, is the natural baſis of ſea-ſalt; and could any method of readily procuring it from this ſalt be fallen upon, it would no doubt be a moſt valuable ſecret.

The demand in this country for foſſil or mineral alkali is ſupplied from the aſhes of kali and other ſea plants, from which it is ſeparated in the ſame manner as the vegetable alkali from the aſhes of other plants. The pureſt kind of aſhes containing this ſalt is called ſoda or barilla, and is imported chiefly from Spain and Portugal; that which is obtained from the ſea-weed growing on our own coaſts, and known by the name of kelp, is very impure, and ſcarce admits of being thoroughly analized according to the rules of chemiſtry.

Both theſe alkalies may be deprived of their fixed air, and rendered pure and cauſtic, by the addition of quick lime. In this ſtate the difference between them is much leſs perceptible than in any other acid; always ſhews that no eſſential charge has taken place in either.

In this highly cauſtic ſtate they deſtroy the parts of animals in a manner ſimilar to that of fire; whence they are called potential cauteries, as the former is called the actual cautery.

Both alkalies attract moiſture from the air when reduced to a ſolid form in their cauſtic ſtate, though neither the foſſil alkali nor its combinations do ſo in any other caſe. In their cauſtic ſtate they only unite with oils, or diſſolve in ſpirit of wine; which laſt they have been ſuppoſed to purify, though it is more than probable that they decompoſe and communicate diſagreeable qualities to it.

The volatile alkali, when procured immediately by the diſtillation of any ſubſtance capable of yielding it, is obtained in a ſtate ſimilar to that in which the alkalies are uſually met with, viz. half mild and half cauſtic. By expoſing the liquid alkali to a great quantity of fixed air, we may at laſt have it perfectly mild and neutraliſed; in which ſtate [illegible]ppears as a white ſalt extremely volatile, though leſs ſo than the pure cauſtic alkali. It diſſolves very readily in water; but unleſs ſome cauſtic ſpirit, or ſome lime or fixed alkali be added, in order to abſtract part of the fixed air, it will ſcarcely exhibit the characteriſtic of volatile alkali, i. e. a pungent and urinous ſmell. The addition of fixed air, however, makes very little difference with regard to the chemical combinations of this ſalt; for as fixed air has a very ſlender power of acidity, it is expelled by every other acid with the greateſt eaſe, and the ſame combinations formed as though it had not been preſent. The only difference is, that when a mild alkali is added to an acid, a ſtrong effervescence takes place by reaſon of the eſcape of the fixed air through the liquid, while with the cauſtic alkali the mixture is made quietly and without diſturbance.

The various combinations of the alkaline ſalts with the different acids, and the neutral compounds thence reſulting, will be exhibited in the Syſtem of CHEMISTRY.

With oil the vegetable fixed alkali forms a ſoap, though leſs perfect than that made with the cauſtic mineral alkali. When combined with fixed air they ſcarcely unite with oils. Boiled with ſulphur, or melted with it in their dry ſtate, they unite into a very fetid compound called ***hepar ſulphuris***, which is ſoluble in water, but totally and very quickly decompoſed by the contact of air.

Vegetable alkali unites with iron, tin, and zinc; corrodes copper, and runs with it into a liquor of a deep blue colour, and joins with lead in fuſion. It does not act upon gold in its metallic ſtate; but if a ſufficient quantity be added to a ſolution of gold in aqua regia, the calx of the metal will be firſt precipitated and afterwards diſſolved.

Vegetable alkali is a principal ingredient in the powders called fluxes, uſed for the fuſion of metalline ores. It promotes the fuſion of earths, and forms glaſs with the cryſtalline kind. It is ſoluble in an equal weight of diſtilled water; and, when expoſed to the air, it ſoon attracts moiſture from it and flows into a liquid. In its cauſtic ſtate it diſſolves in ſpirit of wine, and forms with it a red tincture called Van Helmont's tincture of ſalt of tartar, formerly uſed both as an internal and external remedy, but now fallen into diſrepute.

Foſſil or mineral alkali in its cauſtic ſtate unites with oil into an harder ſoap than that made with vegetable alkali. With ſulphur it forms a hepar ſulphuris in the ſame manner as the vegetable alkali, and yields a tincture with ſpirits of wine, which diſſolves part of the ſalt whilſt hot, but lets it fall again in a cryſtalline form when cold. Gold, ſilver, or quickſilver, are not affected by a ſolution of this ſalt; but copper and tin are diſſolved by it in the open air. It affects tin, lead, regulus of antimony, and cobalt, ſlightly; but acts powerfully upon zinc, and forms a kermes mineral with crude antimony. Copper, iron, biſmuth, zinc, antimony, and regulus of cobalt, fuſed with two parts of foſſil alkali, are almoſt entirely diſſolved in a very ſtrong heat; but tin, lead, and regulus of antimony, treated in the ſame manner, only ſuffer a partial ſolution.

All the alkalies are of conſiderable uſe in medicine, though the particular virtues of vegetable and foſſil alkali have not hitherto been properly aſcertained. It is probable, however, that there muſt be a conſiderable diverſity in their operations on the human body, as the vegetable alkali ſhows itſelf ſo much more acrid and powerful than the foſſil. Both of them unite immediately with acids, and change them into mild neutral ſalts; hence, if any of the ſtrong mineral acids ſhould fall upon any part of the human body, and begin to corrode and give pain, the immediate application of the lixivium tartari, or of a ſolution of any of thoſe alkaline ſalts in water, or of the ſalts themſelves in powder, will deſtroy their cauſticity, and prevent their doing further miſchief: or if any of theſe acids ſhould drop on cloaths, linen, or other ſubſtances, and alkaline ſalts are immediately applied, they will neutralize the acid, and prevent its further corroſion: or if a perſon ſhould, through miſtake, ſwallow any of the mineral acids, or corroſive ſublimate, or any other corroding ſalt which an alkali will decompoſe, the taking down into the ſtomach ſolutions of the alkaline ſalts, or the ſalts themſelves in proper doſes, are the moſt likely means of affording relief, if not given too late.

With regard to the mineral acids, an exception ſeems to take place if oil of vitriol in its concentrated ſtate ſhould happen to be ſwallowed; for this contracts ſuch a degree of heat on the contact of any aqueous fluid as would deſtroy the patient, independent of another cauſe. An inſtance we have ſeen where a perſon unhappily miſtook a bottle of oil of vitriol for water in the night-time. He recovered by ſwallowing inſtantly a great quantity of milk. Another recovered by drinking a bottle of Florence oil.

The vegetable as well as the foſſil alkali applied externally in a cauſtic ſtate, firſt irritate and inflame the ſkin, and afterwards act as fire in mortifying and deſtroying it; and therefore has been much uſed by ſurgeons for opening buboes and other abſceſſes, and for eating away proud or fungous fleſh that ſprouts out from ſores.

The alkaline ſalts, when much diluted with water, have been uſed as waſhes for removing pimples from the face; but if ſuch waſhes are continued long, they are apt to ſpoil the ſkin. It has been proved that alkaline ſalts preſerve animal ſubſtances from putrefaction; on which account ſome practitioners have concluded that they act as ſtrong antiſeptic remedies when ſwallowed as medicines, and are taken up by the lacteal veſſels, and by them carried to the ſubclavian vein to be mixed with the blood. Experience, however, has ſhewn that they have effects directly oppoſite, and that by ſtimulating the veſſels and quickening the circulation, they contribute towards the diſſolution of the vital fluid; of which Dr. Monro ſays he has ſeen ſeveral inſtances.

Alkalies promote the ſecretions in general, particularly by the kidnies; but by the help of warm liquors and bed-clothes, their operation may be directed towards the ſkin. They have alſo been employed in caſes of heartburn, and others where an acid prevails in the ſtomach and bowels, or where theſe organs are loaded with viſcid phlegm. They are likewiſe given with a view to aſſiſt the operation of the bile when it is too weak and inert, either by themſelves, or mixed with purgative or other medicines.

The foſſil alkali has been alleged to be a more powerful ſolvent of the human calculus than the vegetable, though perhaps without any juſt foundation. It is given from 5 to 20 grains three times a-day; and in ſome caſes even to double that quantity. It may be taken in any common liquor, or in clear broth made of lean meat, from which the fat has been ſkimmed off; or the powdered ſalts may be made up into pills or boluſes mixed with liquorice powder, by means of mucilage of gum arabic or conſerve.

The vegetable alkali has long been uſed as a diuretic in dropſies with great ſucceſs; and Dr. Monro affirms, that he has ſeen a number of caſes of anaſarca in which the water was carried off by it. As diuretics, it may be taken from ten grains to half a drachm, or more, two or three times a-day, mixed with ſome diſtilled water, ſyrup, broth, or water-gruel, or with two ounces of white-wine, which partly neutralizes the ſalt. When added to infuſions of juniper-berries, broom-tops, horſe-radiſh, muſtard-ſeed, winter's-bark, &c. in wine and beer, they prove powerful diuretics.

The moſt remarkable property of theſe ſalts, however, is that of diſſolving the human calculus; for the diſcovery of which, Mrs. Stephens, in the year 1740, obtained a parliamentary reward of 5000l. At that time Dr. Jurins being afflicted with the ſtone, tried a number of experiments on theſe medicines; from which he concluded, that their efficacy depended entirely on the alkaline ſalts and lime which they contained; and therefore he began to try what effects a ſoap-ley would have on himſelf. At firſt he took only a few drops, but gradually increaſed his doſe till he came to an ounce, and ſometimes an ounce and an half, in a proper vehicle, in 24 hours. This produced the diſcharge of ſome ſmall calculi, and relieved him of the ſymptoms of the ſtone.

Dr. Hartley, likewiſe, laboured under this complaint; and believing that the efficacy of Mrs. Stephens's medicines depended on the ſoap, lime, and alkaline ſalts which they contained, ordered a paſte to be prepared for himſelf, made of eight ounces of ſoap, one of oyſter-ſhell lime, a drachm of ſalt of tartar, and as much water as formed the whole into a ſoft maſs; of which he took large quantities, and found himſelf greatly relieved, though not cured, as a ſtone was found in his bladder after his death.

Theſe and other inſtances of ſucceſs, ſoon brought the medicines into general uſe: but though many found relief from them, others, particularly thoſe who were afflicted with the ſtone, had all the ſymptoms of their diſtemper aggravated, by the ſalts rendering the blood, and other liquors of the body, particularly the urine, ſharp and acrid, ſo as to irritate and inflame the bladder, which was already in too irritable a ſtate, from the conſtant friction of the calculus lodged within it.

The late experiments of Mr. Scheele and Sir Torburn Bergman, however, have made it evident, that the human calculus is compoſed of a concrete acid, joined to a ſmall portion of animal earth.

Moſt people, therefore, who are afflicted with the ſtone or gravel, ſhould try the efficacy of theſe remedies, rather than ſubmit to the dangerous operation of lithotomy.

The volatile alkali has many of the virtues of the fixed, but affects animal ſubſtances, particularly in its cauſtic ſtate, leſs powerfully than they do. It gives a briſk and ſtrong ſtimulus to the nerves and fibres of living animals; and is therefore employed in diſeaſes where the pulſe is low and the circulation too languid; in low fevers, where the patient is in danger of ſinking; in apoplectic and lethargic diſorders of elderly people of phlegmatic bits, in paralitic caſes, fainting fits, &c. where a briſk and ſtimulating remedy is wanted.

It may be uſed as a diaphoretic and ſudorific in caſes of rheumatiſm, in the end of fevers, catarrhs, and other diſeaſes, where a plentiful diaphoreſis or ſweat is required; and it is principally owing to this quality that the alkalies have obtained their reputation of being efficacious remedies againſt the bites of mad dogs, ſerpents, &c. It is equally efficacious againſt mineral acid poiſons with the fixed alkali.

We have not ſufficient evidence to determine poſitively whether the vegetable alkali be produced by the force of fire, or whether it exiſted originally in the ſubſtances from which it is prepared.

With regard to the volatile alkali, however, we have abundant evidence of its being produced from ſubſtances which could not poſſibly be ſuppoſed to contain it originally. Dr. Stahl aſſures us, that if any dry fixed alkaline ſalt be well rubbed in a mortar with ſuch a quantity of oil of turpentine as is ſufficient to make it of the conſiſtence of a pulp, and digeſted for ſome weeks in a cucurbit or retort, we obtain a volatile alkali. Mr. Geoffroy relates, that having placed a large retort in a ſand furnace, and adapting a tubulated receiver to it, afterwards heating the bottom of the retort red hot, he put into it, by means of a long tube riſing from the upper part of the neck, a powder compoſed of equal parts of nitre and charcoal, on which there came over into the receiver a liquor highly impregnated with volatile alkali. Boerhaave and Macquer have both affirmed, that the vegetative proceſs itſelf produces a volatile alkali; and that the juices got by bruiſing muſtard-ſeed and other alkaleſcent vegetables, as they are called, contain a volatile alkali which efferveſces with acids: but this is denied by Cartheuſer and Vogel, who affirm that they could diſcover no traces of volatile alkali in theſe juices by any experiments they made.

But whatever may be concluded from the experience of former chemiſts, the late diſcoveries of Dr. Prieſtley and Mr. Cavendiſh have deciſively ſhown, that the volatile alkali is by no means a ſimple element or natural principle, but a compound, and which may be artificially prepared. Dr. Prieſtley informs us, that by the union of nitrous air with iron, a volatile alkali is generated; and Mr. Cavendiſh, that by the action of the electric fluid, or pure elementary fire, upon phlogiſticated air, united to a great quantity of elementary fire.

In like manner, if we can ſuppoſe this ſubtile element to enter into the ſubſtance of any kind of earth in ſuch a manner as to exert its peculiar action when that ſubſtance is applied to any other, we may reaſonably conclude that the fixed alkalies alſo are not ſimple and permanent principles, but capable of artificial compoſition and decompoſition.

It is certain that the action of alkaline ſalts is extremely ſimilar to that of fire; and as we know that this element is combined in a latent ſtate with fluids, there can be no abſurdity in ſuppoſing it capable of combining with ſolids.

Alkali, in botany, a name given to ſalt-wort.

ALKALINE, in a general ſenſe, denotes ſomething that has got a tincture of alkali. This term may with propriety be prefixed to the various chemical ſalts in a particular ſenſe.

Alkaline *Acrimony*, in medicine, ſignifies a morbid quality of the blood, nearly tending to putrefaction, which requires the ſame remedies as the ſea-ſcurvy.

ALKALIZATE *Bodies*, in chemiſtry, are thoſe whoſe pores are naturally formed, to be pierced and put into motion by the points of an acid poured over them.

ALKALIZATION, the chemical proceſs of impregnating liquors with alkaline ſalt.

ALKANET, in botany, the Engliſh name of the plant called anchuſa.

ALKEKENGI, in botany, the trivial name of the lawſonia.

ALKERMES, in pharmacy, a compound cordial medicine made in the form of a confection, deriving its name from the kermes-berries uſed in its compoſition.

ALKES, a ſtar in the conſtellation Crater.

ALKUSSA, in ichthyology, a Swediſh name for the fiſh called ſilurus by Artedi.

ALKY, in chemiſtry, ſignifies the ſweet juice which proceeds from lead in infuſion.

ALL-SAINTS, in the calendar, denotes a feſtival celebrated on the firſt of November, in commemoration of all the ſaints in general; which is otherwiſe called All-hallows. The number of ſaints being ſo exceſſively multiplied, it was found too burdenſome to dedicate a feaſt-day to each. In reality, there are not days enough, ſcarce hours enough, in the year, for this purpoſe. Hence an expedient was had recourſe to, by commemorating ſuch in one day as had not their own days.

Boniface IV. in the ninth century, introduced the feaſt of All-Saints in Italy, which was ſoon after adopted into the other churches.

ALL-SOULS, in the calendar, denotes a feaſt-day, held on the ſecond of November, in commemoration of all the faithful deceaſed.

The feaſt of All-Souls was firſt introduced in the eleventh century, by Odilon, abbot of Cluny, who enjoined it on his own order; but it was not before it became adopted by the neighbouring churches.

ALL-SPICE, ſynonymous with Myrtus and Calycanthus.

ALLA, or Allah, the name by which the profeſſors of Mahometaniſm call the Supreme Being.

The term *alla* is Arabic, derived from the verb *alah*, to adore. It is the ſame with the Hebrew *Eloah*, which ſignifies the adorable Being.

ALLAMANDA, in botany; a genus of the monogynia order, belonging to the pentandria claſs of plants. For its characters ſee Syſtem of Botany. There is but one ſpecies, the cathartica, a native of Surinam.

ALLANTOIS, or Allantoides, a gut-ſhaped veſicle inveſting the fœtus of cows, goats, ſheep, &c. filled with an urinous liquor conveyed to it from the urachus. Anatomiſts are not agreed whether the allantois has any exiſtence in the human ſpecies or not. See Syſtem of Comparative Anatomy.

ALLAT, in mythology, a name given to an Arabian idol; the word is derived from the Arabic, *Allah*, God.

ALLAY, the ſame as Alloy.

ALLEGATA; a word anciently ſubſcribed at the bottom of reſcripts and conſtitutions of the emperors; as *ſignata*, or *teſtata*, was under other inſtruments.

ALLEGATION, in civil law, denotes the act of producing certain papers or writings in court, to prove ſome aſſertion already in the pleadings.

It is ſometimes uſed as a quotation proof in a literary ſenſe.

ALLEGEAS, or Allegias, a ſtuff manufactured in the Eaſt-Indies. There are two ſorts of them; ſome are of cotton, and others of ſeveral kinds of herbs, which are ſpun like flax and hemp. Their length and breadth are of eight ells, by five, ſix, or ſeven eighths; and of twelve ells, by three-fourths, or five-eighths.

ALLEGIANCE, in law, is the tie or *ligamen*, which binds the ſubject to the king, in return for that protection which the king affords the ſubject.

It is founded in reaſon and the nature of government; the name and the form are derived to us from our Gothic anceſtors. Under the feodal ſyſtem, every owner of lands held them in ſubjection to ſome ſuperior or lord, from whom, or from whoſe anceſtors, the tenant or vaſſal had received them: and there was a mutual truſt or confidence ſubſiſting between the lord and vaſſal, that the lord ſhould protect the vaſſal in the enjoyment of the territory he had granted him; and, on the other hand, that the vaſſal ſhould be faithful to the lord, and defend him againſt all his enemies.

This obligation on the part of the vaſſal was called his *fidelitas* or fealty: and an oath of fealty was required by the feodal law to be taken by all tenants to their landlord, which is couched in almoſt the ſame terms as our ancient oath of allegiance; except that, in the uſual of fealty, there was frequently a ſaving or exception of the faith due to a ſuperior lord by name, under whom the landlord himſelf was, perhaps, only a tenant or vaſſal. But when the acknowledgment was made to the ſuperior himſelf, who was vaſſal to no man, it was no longer called the oath of fealty, but the oath of allegiance; and therein the tenant ſwore to bear faith to his ſovereign lord, in oppoſition to all men, without any ſaving or exception.

Land held by this exalted ſpecies of fealty, was called *feudum ligium*, a liege fee; *homines ligii*, or liege men; and the ſovereign their *dominus ligius*, or liege lord. And when ſovereign princes did homage to each other for lands held under their reſpective ſovereignties, a diſtinction was always made between ſimple homage, which was only an acknowledgment of tenure, and liege homage, which included the fealty before-mentioned, and the ſervices conſequent upon it.

In Britain, it becoming a ſettled principle of tenure, that all lands in the kingdom are holden of the king as the ſovereign and lord paramount, no oath but that of fealty could ever be taken to inferior lords; and the oath of allegiance was neceſſarily confined to the perſon of the king alone. By an eaſy analogy, the term of allegiance was ſoon brought to ſignify all other engagements which are due from ſubjects to their prince, as well as thoſe duties which were ſimply and merely territorial. And the oath of allegiance, as adminiſtered in England for upwards of 600 years, contained a promiſe, "to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb and terrene honour, and not to know or hear of any ill or damage, without defending him therefrom." But, at the revolution, the terms of his oath being thought, perhaps, to favour too much the notion of non-reſiſtance, the preſent form was introduced by the convention parliament, which is more general and indeterminate than the former; the ſubject only promiſing "that he will be faithful and bear true allegiance to the king," without mentioning "his heirs," or ſpecifying in the leaſt wherein that allegiance conſiſts.

The oath of ſupremacy is principally calculated as a renunciation of the pope's pretended authority; and the oath of abjuration, introduced in the reign of king William, very amply ſupplies the looſe and general texture of the oath of allegiance; it recognizing the right of his majeſty, derived under the act of ſettlement; engaging to ſupport him to the utmoſt of the juror's power; promiſing to diſcloſe all traiterous conſpiracies againſt him; and expreſsly renouncing any claim of the deſcendants of the late pretender, in as clear and explicit terms as the Engliſh language can furniſh.

This oath muſt be taken by all perſons in any office, truſt, or employment; and may be tendered by two juſtices of the peace to any perſon whom they ſhall ſuſpect of diſaffection. But the oath of allegiance may be tendered to all perſons above the age of twelve years, whether natives, denizens, or aliens.

ALLEGIANCE, both expreſs and implied, is however diſtinguiſhed by the law into two ſorts or ſpecies, the one *natural*, the other *local*; the former perpetual, and the latter temporary.

Natural ALLEGIANCE is ſuch as is due from all men born within the king's dominions immediately upon their birth, as natural born ſubjects intitled to the king's protection in every part of the world.

Local ALLEGIANCE is ſuch as is due from an alien, or ſtranger born, for ſo long time as he continues within the king's dominion and protection; and it ceaſes the inſtant ſuch ſtranger transfers himſelf from this kingdom to another.

ALLEGORY, in compoſition, conſiſts in chooſing a ſecondary ſubject, having all its properties and circumſtances reſembling thoſe of the principal ſubject, and deſcribing the former in ſuch a manner as to repreſent the latter.

The principal ſubject is thus kept out of view, and we are left to diſcover it by reflection: and may be compared to an hieroglyphic which raiſes two images in the mind; one ſeen, that repreſents one that is not ſeen: an allegory does the ſame; the repreſentative ſubject is deſcribed, and the reſemblance leads us to apply the deſcription to the ſubject repreſented.

There cannot be a finer or more correct allegory than the following, in which a vineyard is made to repreſent God's own people the Jews:

"Thou haſt brought a vine out of Egypt; thou haſt caſt "out the heathen, and planted it. Thou didſt cauſe it to take "deep root, and it filled the land. The hills were covered "with its ſhadow, and the boughs thereof were like the goodly "cedars. Why haſt thou then broken down her hedges, ſo that "all that paſs do pluck her? The boar out of the wood doth "waſte it, and the wild beaſt doth devour it. Return, we be"ſeech thee, O God of hoſts: look down from heaven, and "behold, and viſit this vine and the vineyard thy right-hand "hath planted, and the branch thou madeſt ſtrong for thyſelf." Pſal. lxxx.

Nothing gives greater pleaſure than an allegory, when the repreſentative ſubject bears a ſtrong analogy, in all its circumſtances, to that which is repreſented. Yet moſt writers are unlucky in their choice, the analogy being generally ſo faint and obſcure, as rather to puzzle than to pleaſe.

Allegories, as well as metaphors and ſimilies, are unnatural in expreſſing any ſevere paſſion which totally occupies the mind; therefore ſhould be carefully avoided in heroics, or ſoliloquies.

ALLEGRO, in muſic, an Italian word, generally written at the beginning of an air, denotes, from quick to ſlow, the ſecond of the five principal degrees of movement diſtinguiſhed in Italic harmony. But we muſt not think that on that account, this movement is proper for gay ſubjects only; it is often applicable to tranſports of paſſion, diſtraction, or deſpair, which partake of nothing leſs than of gaiety.

The diminitive allegretto denotes a more moderated gaiety, and a little leſs vivacity in the meaſure.

Piu ALLEGRO, ſignifies that the part it is joined to ſhould be ſung or played quicker; as

Poco piu ALLEGRO intimates, that the part to which it refers ought to be played or ſung only a little more briſkly than allegro alone requires.

ALLELENGYON, in ancient hiſtory, denotes the tax paid by the rich, for the poor's privilege to be abſent from the army in time of war.

ALLELOPHAGI, in natural hiſtory, the denomination of a certain kind of flies, which entomologiſts affirm, devour each other as their only proper food. Hence the diſtinction heterophagi, or thoſe that fed on other kinds of food, adopted by writers on the ſubject.

ALLELUJA, in botany, a name given by many to the common wood-ſorrel.

ALLELUJAH, or HALLELUJAH, a word ſignifying, *praiſe ye the Lord*, and is to be met with at the beginning and end of ſome pſalms: ſuch is Pſalm cxlv. and thoſe that follow, to the end. Allelujah was ſung upon ſolemn days of rejoicings, Tobit xiii. 12. St. John in tho Revelation (xix, 1, 3, 4, 6.) ſays, that he "heard a great voice of much people in heaven, who ſaid, Allelujah; and the four and twenty elders, and the four beaſts, fell down and worſhipped God that ſat on the throne, ſaying Allelujah." This hymn of joy and praiſes was transferred from the ſynagogue to the church. St. Jerom tells us, that at the funeral of Fabiola ſeveral pſalms were ſung with loud Allelujahs; and that the monks of Paleſtine were awakened, at their midnight watchings, with the ſinging of Allelujahs. So much energy has been obſerved in this term, that the ancient church thought proper to preſerve it, without tranſlating it either into Greek or Latin, for fear of impairing the beauty and ſoftneſs of it. The ſinging Allelujah was oftentimes an invitatory or call to each other to *praiſe the Lord*.

ALLEMAND, a ſort of grave ſolemn muſic, with good meaſure, and a ſlow movement.

ALLEMANDE, a briſk kind of dance, very common in Germany, Switzerland, and France.

ALLEMANNIC, in a general ſenſe, denotes any thing belonging to the ancient Germans.

ALLER, in ancient authors, ſerves to make the expreſſion of ſuperlative ſignification. Hence *aller-good*, is the greateſt good. Sometimes it is written *alder*.

ALLERION, or ALERION, in heraldry, a ſort of eagle without a beak or feet, having nothing perfect but the wings. They differ from martlets by having their wings expanded, whereas thoſe of the martlet are cloſe; and denote Imperialiſts vanquiſhed and diſarmed; for which reaſon they are more comman in French than in German coats of arms.

ALLEU, or ALLODE, ſynonymies of ALLODIUM.

ALLEVIARE, in law, a word uſed in ancient records for paſſing a fine, agreeably to the preſent practice uſed in conveyancing.

ALLEVEURE, a ſmall braſs Swediſh coin, worth about ½d. Engliſh money.

ALLEVIATION, in grammar, denotes the making a thing lighter, and eaſier to bear or endure. It ſtands oppoſed to aggravation.

ALLEVIATION, in medical language, implies an eaſement or freedom from pain. It is generally applied to thoſe remedies which operate inſtantaneouſly.

ALLEY, in gardening, a ſtraight parallel walk, bounded on both ſides with trees, ſhrubs, &c. and uſually covered with gravel or turf.

ALLEY, among builders, denotes a narrow paſſage leading from one place to another.

ALLEY, in perſpective, that which, in order to have a greater appearance of length, is made wider at the entrance than at the termination.

ALLEY, in agriculture, implies the vacant ſpace between the outermoſt row of corn on one bed and the neareſt row to it on the next parallel bed; and it is uſually about four feet in breadth, excluſive of the partitions between the rows of corn in the beds.

ALL-GOOD, in botany, implies the chenopodium, or gooſe foot.

ALL-HEAL, in botany, are names given to two ſorts of plants, namely, Hercules's all-heal, or wound wort, and Clown's all-heal, or hore-hound.

ALLIANCE, in the civil and canon law, the relation contracted between two perſons or two families by marriage.

ALLIANCE is alſo uſed for a treaty entered into by ſovereign princes and ſtates, for their mutual ſafety and defence. In this ſenſe, alliances may be diſtinguiſhed into ſuch as are offenſive, whereby the contracting parties oblige themſelves jointly to attack ſome other power; and into defenſive ones, whereby they bind themſelves to ſtand by and defend each other in caſe they are attacked by others.

Alliance, with the ancient Romans, though a ſort of ſervitude, was much coveted. Ariarathes, we are told by Polybius, offered a ſacrifice to the gods by way of thankſgiving for having obtained this alliance. The reaſon was, that thence-forwards people were ſure not to receive any injuries except from them. There were different ſorts of allies: ſome only united to them by a participation of the privileges of Romans, as the Latini and Hernici; others by their very foundation, as the colonies; others by the benefactions they received from them, as Maſſiniſſa, Eumenes, and Attalus, who owed their kingdoms to Rome; others by free treaties, which laſt, by a long alliance, became ſubjects, as the kings of Bithynia, Cappadocia, Egypt, and moſt of the cities of Greece: laſtly, others by compulſive treaties, and the law of ſubjection, as Philip and Antiochus. For they never granted peace to an enemy, without making an alliance with him; that is, they never ſubdued any people without uſing it as a means of ſubduing others.

Alliances among the Jews and Chaldeans, heifers or calves were ſacrificed; among the Greeks, bulls or goats; and among the Romans, hogs were ſacrificed on this occaſion.

Alliances among the ancient Arabs, were confirmed by drawing blood out of the palms of the hands of the two contracting princes with a ſharp ſtone, dipping herein a piece of their garments, and therewith ſmearing ſeven ſtones, at the ſame time invoking the gods Vrotalt and Alilat, i. e. according to Herodotus, Bacchus and Urania.

ALLIANCE, in a figurative ſenſe, is applied to any kind of union or connection; thus we ſay, there is an alliance between the church and ſtate.

ALLIARIA, in botany, ſignifies dame's violet, whoſe deſcription as a ſynonyme comes under its real name.

ALLIGATI, in Roman antiquity, the baſeſt kind of ſlaves, who were uſually kept fettered. The Romans had three degrees, or orders, of ſlaves or ſervants; the firſt employed in the management of their eſtates; the ſecond in the menial or lower functions of the family; the third called *alligati*, above mentioned.

ALLIGATION, the name of a method of ſolving all queſtions that relate to the mixture of one ingredient with another. See Syſtem of ARITHMETIC, under the heads of Alligation, Medial and Alternate.

ALLIGATOR, in zoology, a ſynonyme of the lacerta crocodilus.

ALIGATOR *Pear*, a fruit well known.

ALLIONIA, in botany, a genus of the monogynia order, belonging to the tetrandia claſs of plants; and in the natural method ranking under the 48th order, *Aggregatæ*. For the characters, ſee Syſtem of BOTANY. The violeacea and incarnata, both natives of America.

ALLIOTH, a ſtar in the tail of the greater bear, much uſed for finding the latitude at ſea.

ALLIOTICUM, a galenical, to cleanſe the blood.

ALLITERATION, an ornament of language chiefly uſed in poetry, and conſiſting in the repetition of the ſame letter at certain intervals. I do not remember to have ever ſeen any ſatisfactory account of alliteration in the writings of the critics.

Many chapters have been compoſed on quantity, on the expreſſion reſulting from different arrangements of long and ſhort ſyllables, and on the powers of pauſes as they are variouſly placed, without a word of alliteration. This is the more extraordinary, as one ſhould think it impoſſible for any man to examine minutely, and, as it were, diſſect a number of verſes, without perceiving the vaſt abundance of this ornament.

I do not pretend to ſay, that the ſweetneſs and energy of verſification depends chiefly on this circumſtance, yet I cannot help believing that it may claim ſome ſhare: for it is a conſtant appearance, as far as I have ever obſerved, that the poets whoſe fame is higheſt for verſification, are moſt extenſive dealers in this article.

The trifling poor appearance of the ornament itſelf, upon a ſuperficial view, and the frequent abuſe of it, are circumſtances indeed which give no encouragement to a ſerious inquiry into its nature and operation. How common is it for writers, who affect to be comic, when in want of other means for raiſing a ſmile, to uſe affected alliteration with ſucceſs. But, in the fine arts, no beauty nor grace is beyond the power of ridicule. The nobleſt attitudes in painting have been rendered laughable by caricatura. St. Paul preaching at Athens, in the deſign of Raphael, appears elegant, noble, and in ſome degree awful. The ſame apoſtle, repreſented by Hogarth in nearly the ſame attitude, pleading before the governor Felix, ſeems altogether ridiculous. So the language and verſification of Milton in the Paradiſe Loſt appear only proper for the moſt elevated ſubjects. In the Splendid Shilling of Philips, they appear equally proper for the loweſt. So fares it alſo with alliteration. Nor ought we to be mortified at the diſcovery, that much of the delight afforded by verſification ariſes from a cauſe ſo pitiful as the repetition of the ſame letter twice, or oftener, on the accented parts of a verſe; for there are many other cauſes of pleaſure, which, when thus detected and taken to pieces, ſeem equally contemptible.

A few lines will ſuffice to illuſtrate this grace taken from Grey, who ſeems to have paid particular attention to it.

"*R*uin ſeize thee, *r*uthleſs king."
"To *h*igh-born *H*oel's *h*arp, or ſoft *L*lewe*l*lyn's *l*ay."
"*W*eave the *w*arp, and *w*eave the *w*oof."
"Stamp we our vengeance *d*eep, and ratify his *d*oom."
"Regardleſs of the *ſ*weeping whirlwind's *ſ*way."
"That huſh'd in grim re*p*oſe, ex*p*ects his ev'ning *p*rey."

Again —

"Eyes that *g*low, and fangs that *g*rin,
"Thoughts that *b*reathe, and words that *b*urn."
"*H*auberk craſh, and *h*elmet ring."

A compoſer who aims at expreſſion will not hunt after fugues; but if they offer, ſpontaneouſly from the ſubject, he will not reject them. So in like manner a good poet ought not to ſelect an epithet merely for beginning with a certain letter, unleſs it ſuits his purpoſe in every other reſpect; for the beauty of alliteration, when happy, is not greater than its deformity when affected. A couplet from Pope will exemplify both; the firſt line being bad, and the ſecond good:

"Eternal beauties grace the *ſ*hining *ſ*cene,
"*F*ields ever *f*reſh, and *g*roves for ever *g*reen."

ALLIUM, from 'αλεω, "to avoid or ſhun," becauſe many ſhun the ſmell of it, GARLIC: a genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking in the 9th order, Spathaceæ. For its characters, ſee Syſtem of BOTANY. Of this genus 40 different ſpecies are enumerated by Linnæus, among which he includes the cepa and porrum, or onions and leeks.

1. The ſativum, or garlic, has a bulbous root, of an irregularly roundiſh ſhape, with ſeveral fibres at the bottom; each root is compoſed of a number of leſſer bulbs, called *cloves* of garlic, incloſed in one common membranous coat, and eaſily ſeparable from one another. All the parts of this plant, but more eſpecially the roots, have an acrimonious, and almoſt cauſtic taſte, wlth a ſtrong offenſive ſmell, which laſt has induced thoſe who preſerved ſome of the ſpecies in gardens on account of their yellow flowers, to eradicate them.

This pungent root warms and ſtimulates the ſolids, and attenuates tenacious juices; for which it is well adapted, on account of its being very penetrating; inſomuch that, when applied to the feet, its ſcent is ſoon diſcovered in the breath; and, when taken internally, its ſmell is communicated to the urine, or the matter of an iſſue, and perſpires through the pores of the ſkin. Hence in cold eucophlegmatic habits, it proves a powerful expectorant, diuretic, and emmenagogue; and, if the patient is kept warm, ſudorific.

It is of great ſervice in humoral aſthmas and catarrhous diſorders of the breaſt, and in other diſorders proceeding from a laxity of the ſolids, and cold ſluggiſh indiſpoſitions of the fluids.

It is alſo frequently of ſervice in the dropſy; in the beginning of which it is particularly recommended by Sydenham, as a warm ſtrengthening medicine: we have even many examples where it acts ſo powerfully as a diuretic, as to carry off all the water of dropſies. It may be taken the length of a dram or two in ſubſtance for a doſe. We have a ſyrup and oxymel made with it, which may be employed for the ſame purpoſes as the garlic in ſubſtance; but they are moſtly uſed in pulmonic diſorders.

Externally applied, it inflames and ulcerates the ſkin, and is ſometimes employed for this uſe in ſinapiſms.

It has likewiſe been recommended by Sydenham as a moſt powerful revellent; for which purpoſe he was led to make uſe of it in the confluent ſmall-pox. His method was to cut the root in pieces, and apply it, tied in a linen cloth, to the ſoles of the feet, about the eighth day of the diſeaſe, after the face began to ſwell; renewing it once a-day till the danger was over. When made into an unguent with oils, and applied externally, garlic is ſaid to reſolve and diſcuſs cold tumors, and has been by ſome greatly celebrated in cutaneous diſorders.

The acrimonious qualities of this root, however, render it manifeſtly improper on many occaſions. Its liberal uſe is apt to occaſion head-achs, flatulencies, thirſt, febrile heats, inflammatory diſtempers, and ſometimes diſcharges of blood from the hemorrhoidal veſſels. In hot bilious conſtitutions, where there is already a degree of irritation, where the juices are too thin and acrimonious, or the viſcera unſound, it never fails to aggravate the diſtemper.

In Kamtſchatka, the allium urſinum, or wild garlic, is very common and uſeful in medicine as well as food. Both Ruſſians and natives gather it in great quantities for winter ſervice. They ſteep it in water, then mix it with cabbage, onions, and other ingredients, and form out of them a ragout which they eat cold. It is alſo their principal remedy for the ſcurvy: for as ſoon as this plant appears above the ſnow, they ſeem to put this dreadful diſorder at defiance, and find a cure almoſt in its worſt ſtages.

Garlic is very hardy, and will thrive in almoſt any ſoil or ſituation; and is eaſily propagated either by the roots or ſeeds.

2. The aſcalonicum, or eſchalot, was found wild in Paleſtine by Dr. Haſſelquiſt. The root is conglobate, conſiſting of many oblong roots bound together by thin membranes. Each of theſe ſmall roots ſends forth two or three fiſtulous, long, awl-ſhaped leaves, iſſuing from a ſheath, and are nearly like thoſe of the common onion. The root of this ſpecies is very pungent, has a ſtrong, but not unpleaſant ſmell, and therefore is generally preferred to the onion for making high-flavoured ſoups and gravies.

3. The ſcorodopraſum, or rokambole, grows naturally in Denmark and Sweden. It hath a heart-ſhaped ſolid root, which ſtands ſidewiſe of the ſtalk. The roots are uſed for the ſame purpoſe as the former.

4. The ſchœnopraſum, cives, or ſhives, is an inhabitant of Siberia, and is a very ſmall plant compared with the former, the leaves and ſtems ſeldom exceeding ſix inches in length, and the roots never producing any bulbs. Its taſte, ſmell, and virtues, are much the ſame as thoſe of the common onion.

5. The cepa, or common onion, differs from the garlic only in the ſwelling pipy ſtalk, which is much larger in the middle than at either end. Their nature is to attenuate thick, viſcid juices; conſequently, a plentiful uſe of them in cold phlegmatic conſtitutions, muſt prove beneficial. Many people ſhun them on account of the ſtrong, diſagreeable ſmell they communicate to the breath. This may be remedied by eating a few raw parſley-leaves immediately after, which will effectually overcome the ſcent of the onions, and cauſe them to ſit more eaſy on the ſtomach.

The varieties are, the Spaniſh, and the Egyptian onions. They are propagated by ſeeds, which ſhould be ſown the latter end of February, or the beginning of March, on good, light, rich ground, well dug and levelled, and cleared from weeds.

The ſcallions, or eſcallions, and Welſh onions, were formerly in great repute; both of which never form any bulbs at the roots, and are chiefly uſed in the ſpring for green onions.

6. The portum, or leek, has been ſo long cultivated, that its native place of growth cannot be traced. It is undoubtedly the ſame as that mentioned in Numbers xi. where it is ſaid the Iſraelites longed for leeks in conjunction with onions; and are now in great eſteem with the Welſh and Iriſh, as well as the Dutch and Flemiſh nations.

ALLOBROGES (Inſcriptions, Livy, Velleius, Flarus); from *allobrox* (Horace): a people of Gallia Narbonenſis, ſituated between the rivers Iſara and Rhodanus, and the Lacus Lemanus; commended by Cicero for their fidelity, diſcommended by Horace on account of their fondneſs for novelty.

ALLOCATION denotes the admitting or allowing of an article of an account, eſpecially in the exchequer. Hence,

Allocatione Facienda, is a writ directed to the lord treaſurer, or barons of the exchequer, commanding them to allow an accountant ſuch ſums as he has lawfully expended in the execution of his office.

ALLOCATO Comutato, or Comitatu, implies a new writ of exigent iſſued before any other county court is held, on account of the former not being complied with.

ALLOCUTIO, an oration or ſpeech of a general addreſſed to his ſoldiers, to animate them to fight, to appeaſe ſedition, or to keep them to their duty. A mount of earth was, in ancient times, uſually raiſed upon theſe occaſions, as a kind of tribunal of turf. From this the general pronounced his harangue to the army, which was ranged in ſeveral ſquadrons round him, with their captains and other officers at their head. When the time and circumſtances would not admit of a formal harangue, the general went through the ranks, and called each by his name, putting them in mind of their courage upon former occaſions, mentioning the victories they had won, and making promiſes of ſpoils and booty.

ALLODIAL, ſynonymous with Allodium, or in a general ſenſe, implies an inheritance, held without any acknowledgment to a ſuperior; contradiſtinguiſhed from feudal. In a modern ſenſe, it is underſtood by that well-known epithet, freehold. See Syſtem of Laws, under the article Freehold.

ALLODIARIUS, in law, the lord paramount of a manor, or proprietor of a barony or lordſhip.

ALLODIUM, or Alleud, denotes lands which are the abſolute property of their owner, without being obliged to pay any ſervice or acknowledgment whatever to a ſuperior lord.

ALLOPHYLLUS, in botany; a genus of the monogynia order, belonging to the octandria claſs of plants. For the characters ſee Syſtem of Botany. There is but one ſpecies, the zeylanicus, a native of Ceylon.

ALLONGE, in fencing, ſignifies a paſs or thruſt with a ſmall ſword, at an antagoniſt or enemy.

ALLOTING, or Allotment of Goods, in matters of commerce, is when a ſhip's cargo is divided into ſeveral parts, bought by divers perſons, whoſe names are written on as many pieces of paper, which are applied by an indifferent perſon to the ſeveral lots or parcels; by which means the goods are divided without partiality.

ALLOY, or Allay, ſignifies a proportion of a baſer metal mixed with a finer one.

The alloy of gold is eſtimated by carats, that of ſilver by pennyweights.

In different nations, different proportions of alloy are uſed; whence their monies are ſaid to be of different degrees of fineneſs or baſeneſs, and are valued accordingly in foreign exchanges.

The chief reaſons alledged for the alloying of coin, are: 1. The mixture of the metals, which, when ſmelted from the mine, are not perfectly pure. 2. The ſaving the expence it muſt otherwiſe coſt if they were to be refined. 3. The neceſſity of rendering them harder, by mixing ſome parts of other metals with them, to prevent the diminution of weight by wearing in paſſing from hand. 4. The melting of foreign gold or coin which is alloyed. The charges of coinage, which muſt be made good by the profit ariſing from the money coined. 6, and laſtly, The duty belonging to the ſovereign, on account of the power he has to cauſe money to be coined in his dominions.

Alloy, in a more general ſenſe, implies a chemical proceſs of the union of different metallic matters.

ALLSEED, an obſolete name for flax-ſeed.

ALLSPICE, a trivial name given to pimento, a ſpecies of pepper.

ALLUM, the ſame as Alum, under which orthography the word properly belongs, as the former as well as the corrupt word Allom, is contrary to its derivative power from the Greek, ἅλς, *ſalt*.

ALLUMEN Plumosum, in chemiſtry, implies the baſilian ſublimate of mercury, formed of arſenic, united with vitriolic acid.

Allumen Scagliolæ, or Scaiolæ, a flaky ſtone, ſometimes called *lapis ſpecularis*, which the antients called *Schiſton*.

Allumen Catini, ſignifies the alkaline taſte of the herb Kali, uſed in making glaſs, and is a ſynonyme of alkali.

Allumen Foecis, a ſort of powder made from the lees of wine, much uſed by the Italian ladies to dye their hair yellow, a colour much admired in that country.

ALLUMINOR, from the French *allumer*, "to lighten," is uſed for one who coloureth or painteth upon paper or parchment; and the reaſon is, becauſe he gives light and ornament by his colours to the letters or other figures. Such ornaments are ſtiled illuminations. The word is uſed in ſtat. 1. R. III. cap. 9. But now ſuch a perſon is called a limner.

ALLUMINOUS, an epithet, applied to ſuch things as partake of the nature of allum. Hence all mineral ſprings are ſaid to be alluminous, as being impregnated with particles of that ſalt.

ALLUSION, in rhetoric, a figure by which ſomething is applied to, or underſtood of, another, on account of ſome ſimilitude between them.

ALLUVION, in law, denotes the gradual increaſe of land along the ſea-ſhore; or on banks of rivers.

ALLY, in matters of polity, a ſovereign prince or ſtate that has entered into alliance with others.

ALMACANTERS, a ſynonyme of Almucanters.

ALMADE, or Almadie, a kind of canoe, or ſmall veſſel, about four fathoms long, commonly made of bark, and uſed by the negroes of Africa.

ALMADIE is alſo the name of a kind of long-boats, fitted out at Calicut, which are eighty feet in length, and ſix or ſeven in breadth. They are exceedingly ſwift, and are otherwiſe called cathuri.

ALMAGEST, in matters of literature, is particularly uſed for a collection or book compoſed by Ptolemy, containing various problems of the ancients both in geometry and aſtronomy.

Almagest is alſo the title of other collections of this kind. Thus, Riccioli has publiſhed a book of aſtronomy, which he calls the New Almageſt; and Pluckenet, a book which he calls Almageſtrum Botanicum.

ALMAGRA, a fine deep red ochre, with ſome admixture of purple, very heavy, and of a denſe yet friable ſtructure, and rough duſty ſurface. It adheres very firmly to the tongue, melts freely and eaſily in the mouth, is of an auſtere and ſtrongly aſtringent taſte, and ſtains the ſkin in touching. It is the Sil Atticum of the antients: it ferments very violently with acid menſtruums; by which ſingle quality, it is ſufficiently diſtinguiſhed from the Sil Syricum, to which it has in many reſpects a great affinity. It is found in immenſe quantities in many parts of Spain. It is uſed in painting, and in medicine as an aſtringent.

ALMALECI, in medical hiſtory, implies a ſyſtem of Arabian phyſic, in much eſteem by the ancients.

ALMANAC, or Almanack, a book, or table, containing a calendar of days and months, the riſing and ſetting of the ſun, the age of the moon, the eclipſes of both luminaries, &c. Authors are divided with regard to the etymology of the word; ſome deriving it from the Arabic particle al, and manach, to count; ſome from almanah, new-year's gifts, becauſe the Arabian aſtrologers uſed at the beginning of the year to make preſents of their ephemerides; and others, from the Teutonic almaen-achte, obſervations on all the months. Mr. Johnſon derives it from the Arabic particle al, and the Greek *μην*, a month. But the moſt ſimple etymology appears from the common ſpelling; the word being compoſed of two Arabic ones, al manack, which ſignify the diary.

Regiomontanus appears to have been the firſt in Europe, who reduced almanacks into their preſent form and method, gave the characters of each year and month, foretold the eclipſes and other phaſes, calculated the motions of the planets, &c. His firſt almanack was publiſhed in 1474.

Almanacks differ from one another, chiefly, in containing ſome more, others fewer, particulars.

The eſſential part is the calendar of months and days, with the riſings and ſettings of the ſun, age of the moon, &c. To theſe are added various parerga, aſtronomical, meteorological, chronological, political, rural, &c. as calculations and accounts of eclipſes, ſolar ingreſſes, prognoſtics of the weather, tables of the tides, terms, &c. liſts of poſts, offices, dignities, public inſtitutions, with many other articles political as well as local, and differing in different countries.

The modern almanack anſwers to the faſti of the ancient Romans.

Almanacks for one year printed on one ſide of paper, pay for duty 4d.; thoſe for more years pay for three years 1d.; but perpetual almanacks are to pay only for three years at 2d. Out of the duties by this act there ſhall be paid to each univerſity £.500 per ann. half yearly, at Midſummer and Chriſtmas, and the ſurplus ſhall be paid into the exchequer to go to the ſinking fund. Selling unſtamped almanacks incurs the ſame penalty as for ſelling unſtamped newſpapers. Almanacks in bibles and common prayer books are exempted.

Almanack, among antiquaries, is alſo the name given to a kind of inſtrument, uſually of wood, inſcribed with various figures and Runic characters, and repreſenting the order of the feaſts, dominical letters, days of the week, and golden number, with other matters neceſſary to be known throughout the year; uſed by the ancient northern nations, in their computations of time, both civil and eccleſiaſtical.

Almanacks of this kind are known by various names, among the different nations wherein they have been uſed; as rimſtocks, Primſtaries, runſtocks, runſtaffs, *Scipiones Runici*, *Baculi Annales*, clogs, &c. They appear to have been uſed only by the Swedes, Danes, and Norwegians. From the ſecond of theſe people, their uſe was introduced into England, whence divers remains of them in the counties.

ALMANIA, in Arabian aſtronomy, or rather aſtrology, ſignifies the dominion one planet has over another.

ALMANDIN, or Alabandin, a precious ſtone, of the ruby kind, of great value.

ALMARIA, in eccleſiaſtical and other ancient records, implied the archives of a church, or the like. Hence Almarian laws, or laws of uſage.

ALMARIC *Hereſy*, a tenet broached in France by one Almaric, in the year 1209. It conſiſted in affirming, that every Chriſtian was actually a member of Chriſt; and that without this faith no one could be ſaved.

His followers went farther, and affirmed, that the power of the Father laſted only during the continuance of the Moſaic law; that the coming of Chriſt introduced a new law; that at the end of this began the reign of the Holy Ghoſt; and that now confeſſion and the ſacraments were at an end, and that every one is to be ſaved by the internal operations of the Holy Spirit alone, without any external act of religion. Their tenets were condemned by a public decree of the council of Sens, in the year 1209.

ALME, or Alma, ſinging and dancing girls in Egypt, who, like the Italian *improviſatori*, can occaſionally pour fourth "unpremeditated verſe." They are called Almé, from having received a better education than other women. They form a celebrated ſociety in this country. To be received into it, according to Mr. Savary, it is neceſſary to have a good voice, to underſtand the language well, to know the rules of poetry, and be able to compoſe and ſing couplets on the ſpot, adapted to the circumſtances. The Almé know by heart all the new ſongs. Their memory is furniſhed with the moſt beautiful tales. There is no feſtival without them; no entertainment of which they do not conſtitute the ornament. They are placed in a roſtrum, from whence they ſing during the repaſt. They then deſcend into the ſaloon, and form dances which have no reſemblance to ours. They are pantomime ballets, in which they repreſent the uſual occurrences of life.

Theſe Almé are ſent for into all the harams. They teach the women the new airs; they amuſe them with amorous tales, and recite in their preſence poems, which are ſo much the more intereſting, as they furniſh a lively picture of their manners. Theſe girls, who have a cultivated underſtanding, are very agreeable in converſation. They ſpeak their language with purity. The habit of dedicating themſelves to poetry renders the ſofteſt and moſt ſonorous expreſſions familiar to them. They repeat with a great deal of grace. In ſinging, nature is their only guide. Sometimes two of them ſing together, but always with the ſame voice. It is the ſame with an orcheſtra, where all the inſtruments playing in uniſon execute the ſame part.

The Almé aſſiſt at the marriage ceremonies, and march before the bride playing on inſtruments. They make a figure likewiſe at funerals, and accompany the proceſſion, ſinging ſorrowful airs. They break forth into groans and lamentations, and give every ſign of grief and deſpair. Theſe women are paid very high, and ſeldom appear but among the grandees and rich men.

The common people have alſo their Almé. They are girls of the ſecond claſs, who try to imitate the former; but they have neither their elegance, their graces, or their knowledge.

ALMEHRAB, in the Mahometan cuſtoms, a nich in their moſques, pointing towards the kebla, or temple of Mecca, to which they are obliged to bow in praying.

ALMEISAR, a celebrated game among the ancient Arabs, performed by a kind of caſting of lots with arrows, ſtrictly forbid by the law of Mahomet, on account of the frequent quarrels occaſioned by it.

The manner of the game was thus: A young camel being brought and killed, was divided into a number of parts. The adventurers, to the number of ſeven, being met, eleven arrows were provided without heads or feathers; ſeven of which were marked, the firſt with one notch, the ſecond with two, the third with three, &c. the other four had no marks. Theſe arrows were put promiſcuouſly into a bag, and thus drawn by an indifferent perſon. Thoſe to whom the marked arrows fell, won ſhares in proportion to their lot; the reſt to whom the blanks fell were entitled to no part of the camel, but obliged to pay the whole price of it. Even the winners taſted not of the fleſh themſelves more than the loſers, but the whole was diſtributed to the poor.

ALMENE, in commerce, a weight of two pounds uſed to weigh ſaffron in ſeveral parts of the Eaſt Indies.

Almene, a ſynonyme of the African lotus or acanthus.

ALMIGGIM Wood, a name given in the Scriptures to the Indian pine tree, which implies light and white.

ALMIZADIR, in alchemy, implies the ſame as alkaheſt.

ALMOGIZA, the Arabic name of the limb of the aſtrolobe.

AL-MOHARRAM, the name of the firſt or holy moon of the Arabian year.

ALMOND, the fruit of the almond tree, whoſe botanic name comes under the article Amygdalus.

Almond, in commerce, a meaſure by which the Portugueſe ſell their oil; 26 almonds make a pipe.

Almonds, in anatomy, a name ſometimes given to two glands, generally called the tonſils.

Almonds, among lapidaries, ſignify pieces of rock cryſtal, uſed in adorning branch-candleſticks, &c. on account of the reſemblance they bear to the fruit of that name.

Almond-Furnace, among refiners, that in which the ſlags of litharge, left in refining ſilver, are reduced to lead again by the help of charcoal.

ALMONER, in its primitive ſenſe, denotes an officer in religious houſes, to whom belonged the management and diſtribution of the alms of the houſe. By the ancient canons, all monaſteries were to ſpend at leaſt a tenth part of their income in alms to the poor. The almoner of St. Paul's is to diſpoſe of the monies left for charity, according to the appointment of the donors, to bury the poor who die in the neighbourhood, and to breed up eight boys to ſinging, for the uſe of the choir. By an antient canon, all biſhops are required to keep almoners.

Lord Almoner, or Lord High Almoner, of England, is an eccleſiaſtical officer, generally a biſhop, who has the forfeiture of all deodands, and the goods of *felos de ſe*, which he is to diſtribute among the poor. He has alſo, by virtue of an ancient cuſtom, the power of giving the firſt diſh from the king's table to whatever poor perſon he pleaſes, or, inſtead of it, an alms in money.

Great Almoner, Grand Aumonier, in France, is the higheſt eccleſiaſtical dignity in that kingdom. To him belongs the ſuperintendency of all hoſpitals and houſes of lepers. The king receives the ſacrament from his hand; and he ſays maſs before the king in all grand ceremonies and ſolemnities.

Almoner is alſo a more faſhionable title given by ſome writers to chaplains. In this ſenſe we meet with almoner of a ſhip, almoner of a regiment, &c.

ALMONRY, or Aumbry, the office or lodgings of the almoner; alſo the place where alms are given.

ALMS, a general term for what is given out of charity to the poor.

In the early ages of chriſtianity, the alms of the charitable were divided into four parts; one of which was allotted to the biſhop, another to the prieſts, and a third to the deacons and ſubdeacons, which made their whole ſubſiſtence; the fourth part was employed in relieving the poor, and in repairing the churches.

No religious ſyſtem is more warm in its exhortations to almsgiving, than the Mahometan. The alcoran repreſents alms as a neceſſary means to make prayer be heard. Hence that ſaying of khalifs: "Prayer carries half way to God, faſting brings us to the door of his palace, and alms introduces him into the preſence chamber."

Alms alſo denotes lands or other effects left to churches or religious houſes, in the catholic perſuaſion, on condition of praying for the ſoul of the donor.

Free Alms was that which is liable to no rent or ſervice.

Reasonable Alms was a certain portion of the eſtates of inteſtate perſons, allotted to the poor.

Alms-Box, or Chest, or ſmall cheſt or coffer, called by the Greeks Κιβώτιον, wherein anciently the alms were collected, both at church and at private houſes.

The alms cheſt in Engliſh churches is a ſtrong box, with a hole in the upper part, having three keys, one to be kept by the parſon or curate, the other two by the churchwardens. The erecting of ſuch alms-cheſt in every church is enjoined by the book of canons, as alſo the manner of diſtributing what is thus collected among the poor of the pariſh.

Alms-House, a kind of hoſpital for the maintenance of a certain number of poor, aged, or diſabled people.

ALMUCANTARS, in aſtronomy, an Arabic word denoting circles of the ſphere paſſing through the centre of the ſun, or a ſtar parallel to the horizon, being the ſame as parallels of altitude.

Almucantars-Staff, is an inſtrument uſually made of pear-tree or box, having an arch of 15 degrees; uſed to take obſervations of the ſun, about the time of its riſing and ſetting; in order to find the amplitude, and conſequently the variation of the compaſs.

ALMUCIUM, denotes a kind of cover for the head, worn chiefly by monks and eccleſiaſtics: it was of a ſquare form, and ſeems to have given riſe to the bonnets of the ſame ſhape ſtill retained in univerſities and cathedrals.

ALMUGEA, in aſtrology, ſignifies the diſtance of five ſigns from each other, in calculating the five planets that are ſaid to preſide over nativity.

ALMUGIM, or Almug-Tree, a certain kind of wood mentioned in the firſt book of Kings, (x. 11.) which the Vulgate tranſlates *ligna thyina*, and the Septuagint *wrought wood*. Scripture tells us the almug-tree was uſed for making muſical inſtruments, ſtair-caſes, &c. The word *thyinum* is a name for the citron-tree, known to the ancients, and very much eſteemed for its ſweet odour and great beauty. It came from Mauritania. The almug-tree, or almugim, algumin, or ſimply gummim, taking *al* for a kind of article, is therefore by the beſt commentators underſtood to be an oily and gummy ſort of wood; and particularly that ſort of tree which produces the gum ammoniac, which is alſo thought to be the ſame with the ſhittim-wood, of which there is ſuch frequent mention made by Moſes.

ALMUTAZAPHUS, a name given to the head magiſtrate of the police of Arragon in Spain.

ALNABATI, in medicine, the ſame as the ſiliqua dulcis or carob-tree.

ALNAGE, or Aulnage, the meaſuring of woollen manufactures by the ell. It was at firſt intended as a proof of the goodneſs of that commodity, and accordingly a ſeal was invented as a mark that the commodity was made according to the ſtatute;

ALNAGER, Alneger, Aulneger, q. d. meaſurer by the ell, ſignifies a ſworn public officer, who, by himſelf or deputy, is to look to the aſſize of woollen cloth throughout the land, i. e. the length, width, and work thereof; and to the ſeals for that purpoſe ordained. The office of king's aulneger ſeems to have been derived from the ſtatute of Richard I. A. D. 1197, which ordained, that there ſhould be only one weight and one meaſure throughout the kingdom. His buſineſs was to meaſure all cloths made for ſale, till the office was aboliſhed by the ſtatute 11 and 12 W. III. cap. 20.

ALNAM, the botanical name of the herb penny-royal.

ALNASI, the muſſulman's notion of adopting a prophane moon for the obſervance of the rites of an holy one.

ALNUS, the alder-tree, a ſpecies of betula.

Alnus, in the ancient theatres, that part which was moſt diſtant from the ſtage.

ALOA, in Grecian antiquity, a feſtival kept in honour of Ceres by the huſbandmen, and ſuppoſed to reſemble our harveſt-home.

ALOE, in botany, a genus of the monogynia order, belonging to the hexandria claſs of plants; and, in the natural method, ranking under the 10th order, *coronariæ* For the characters ſee Syſtem of Botany. Of this genus, botanical writers enumerate ten ſpecies; of which the moſt remarkable are,

1. The diſticha, or ſoap aloe. This ſeldom riſes above two feet high. The leaves are very broad at the baſe, where they cloſely embrace the ſtalk, and gradually decreaſe to a point. The edges are ſet with ſharp ſpines, and the under leaves ſpread open horizontally every way. Theſe are of a dark green colour ſpotted with white. The flowers grow in umbels on the tops of the ſtalks, and are of a beautiful red colour, and appear in Auguſt and September.

2. The variegata, or partridge-breaſt aloe, is a low plant, ſeldom riſing above eight inches high. The leaves of this are triangular, and curiouſly veined and ſpotted, ſomewhat like the feathers of a partridge's breaſt. The flowers grow in very looſe ſpikes, and are of a fine red colour tipt with green.

3. The viſcoſa, with funnel-ſhaped flowers, grows near a foot high, with triangular leaves of a dark green colour.

4. The ſpiralis, with oval crenated flowers, grows ſomewhat like the former.

5. The linguisformæ, or tongue-aloe, has its leaves about ſix inches in length, and ſhaped like a tongue.

6. The margaritifera, or pearl aloe, is a very beautiful plant. It is ſmaller than moſt of the aloe kind. The leaves are ſhort, very thick, ſharp-pointed, and turning down, with a large thick end, appear there triangular. The colour of the leaves is a fine green, ſtriped in an elegant manner with white, and frequently tipped with red at the point. This aloe is ſingular in not having the bitter reſinous juice with which the leaves of moſt others abound; when a leaf of this ſpecies is cut, what runs from it is watery, colourleſs, and perfectly inſipid.

7. The perfoliata, or ſocotorine aloe, hath long, narrow, ſucculent leaves, which come out without any order, and form large heads. The ſtalks grow three or four feet high, and have two, three, and ſometimes four, of theſe heads branching out from it.

The proper earth for planting theſe vegetables in, is one half freſh light earth from a common, and the reſt an equal mixture of white ſea-ſand and ſifted lime rubbiſh.

The aloe is a kind of ſymbolic plant to the mahometans, eſpecially in Egypt, and in ſome meaſure dedicated to the offices of religion; for whoever returns from a pilgrimage to Mecca, hangs it over his ſtreet door, as a token of his having performed that holy journey.

Aloes is a ſtimulating ſtomachic purge, which, given in ſmall quantities, operates mildly by ſtool; but in large doſes acts roughly, and often occaſions an irritation about the anus, and ſometimes a diſcharge of blood. It is a good opening medicine to people of a coſtive habit, or who live a ſedentary life; and alſo to thoſe whoſe ſtomach and bowels are loaded with phlegm or mucus, or who are troubled with worms, or are debilitated; becauſe at the ſame time that it carries off thoſe viſcid humours which pall the appetite, and overload the inteſtines, it ſerves as a ſtrengthener and bracer.

It is given in ſubſtance from five grains to a ſcruple. As it is a ſlow-working purge; it is generally taken at bed-time, and operates the next day.

ALOETICS, medicines wherein aloes is the chief ingredient.

ALOEUS, a ſpecies of the firſt order of the beetle kind, enumerated by Linnæus. This inſect is a native of America only. See Syſtem of Entomology.

ALOGIANS, in church hiſtory, a ſect of ancient heretics, who denied that Jeſus Chriſt was the Logos, and conſequently rejected the goſpel of St. John. The word is compounded of the privative *α*, and *λογος*, q. d. without Logos or Word. Some aſcribe the origin of the name, as well as of the ſect of Alogians, to Theodore of Byzantium, by trade a currier; who having apoſtatized under the perſecution of the emperor Severus, to defend himſelf againſt thoſe who reproached him therewith, ſaid, that it was not God he denied, but only man. Whence his followers were called in Greek *αλογοι*, becauſe they rejected the word. They made their appearance toward the cloſe of the ſecond century.

ALOGOTROPHIA, among phyſicians, a term ſignifying the unequal growth or nouriſhment of any part of the body.

ALOIDES, in botany, a name given to the freſh-water aloe, which Linnæus calls ſtratiotes.

Aloides, in mythology, two giants, ſaid to be the ſons of Aloeüs, whoſe names were Otus and Ephialtes; they attempted to heap Oſſa on Olympus, and Pelion on Oſſa, in order to climb up to heaven and dethrone Jupiter; but they were ſhot to death by the arrows of Apollo and Diana.

Virgil makes Æneas relate, that he ſaw theſe two giants in hell.

Hic et Aloidas geminos, immania vidi,
Corpora, qui manibus magnum reſcindere cælum
Aggreſſi.

Here lie th'Atlean twins, (I ſaw them both)
Enormous bodies of gigantic growth,
Who dar'd in fight the thund'rer to defy,
Affect his heaven and force him from the ſky.
Dryden.

Mr. Pope's Homer relates, that Mars, the god of War, was ſhut up in priſon by them for thirteen months, till relieved by Mercury.

The mighty Mars in mortal fetters bound,
And lodg'd in brazen dungeons under ground,
Full thirteen moons impriſon'd, roar'd in vain;
Otus and Ephialtes held the chain:
Perhaps had periſh'd, had not Hermes' care,
Reſtor'd the groaning god to upper air.

ALOOF, has frequently been mentioned as a ſea term; in common diſcourſe to imply *at a diſtance*; and the reſemblance of the phraſes *keep a loof*, and *keep a luff*, or *keep the luff*, in all probability gave riſe to this conjecture. It denotes a lee-ſhore, in which ſituation the pilot might naturally apply it in the ſenſe commonly underſtood, viz. keep *all off*, or quite off.

ALOPECIA, a term uſed among phyſicians to denote a total falling off of the hair from certain parts, occaſioned either by the defect of nutritious juice, or by its vicious quality corroding the roots of it, and leaving the ſkin rough and colourleſs.

The word is formed from *αλωπηξ*, *vulpes*, "a fox;" whoſe urine, it is ſaid, will occaſion baldneſs; or becauſe it is a diſeaſe which is common to that creature.

In caſes where the baldneſs is total, a quantity of burdock roots ſhould be bruiſed in a marble mortar, and then boiled in white wine until there remains only as much as will cover them. This liquor, carefully ſtrained off, is a perfect cure for baldneſs, by waſhing the head every night with ſome of it warm. A freſh cut onion, rubbed on the part until it be red and itch, is likewiſe a cure for baldneſs.

ALOPECURUS, or Fox-tail grass, in botany: a genus of the triandria digynia claſs; and in the natural method ranking under the 4th order, *Gramina.*

ALOPEX, in zoology, a ſpecies of the canis, with a ſtrait tail and black tip. It is commonly called the *field fox*.

ALOSA, or Aloxe, the ſhad, or mother of herrings, a ſpecies of the clupea.

ALPHA, the name of the firſt letter of the Greek alphabet, anſwering to our A. As a numeral, it ſtands for one, or the firſt of any thing. It is particularly uſed, among ancient writers, to denote the chief or firſt man of his claſs or rank. In this ſenſe, the word ſtands contradiſtinguiſhed from *beta*, which denotes the ſecond perſon. Plato was called the *Alpha* of the wits: Eratoſthenes, keeper of the Alexandrian library, whom ſome called a Second Plato, is frequently named *beta*.

Alpha is alſo uſed to denote the beginning of any thing. In which ſenſe it ſtands oppoſed to *omega*, which denotes the end. Theſe two letters were made the ſymbols of Chriſtianity; and accordingly were engraven on the tombs of the ancient Chriſtians, to diſtinguiſh them from thoſe of idolaters.

ALPHABET, the natural or cuſtomary ſeries of the ſeveral letters of a language. The word is formed from *alpha* and *beta*, the firſt and ſecond letters of the Greek alphabet. The number of letters is different in the alphabets of different languages. The Engliſh alphabet contains 26 letters; the French 23; the Hebrew, the Chaldee, Syriac, and Samaritan, 22 each; the Arabic 28; the Perſian 31; the Turkiſh 33; the Georgian 36; the Coptic 32; the Muſcovite 43; the Greek 24; the Latin 22; the Sclavonic 27; the Dutch 26; the Spaniſh 27; the Italian 20; the Ethiopic and Tartarian, each 202; the Indians of Bengal 21; the Barameſe 19. The Chineſe have, properly ſpeaking, no alphabet, except we call their whole language by that name; their letters are words, or rather hieroglyphics, amounting to about 80,500.

Among the European nations I find none who can pretend any right to the diſcovery of letters. All of them derived the art from the Romans, excepting only the Turks, who had it from the Arabians. The Romans never laid claim to the diſcovery; but confeſſed that they derived their knowledge from the Greeks, and the latter owned that they had it from the Phœnicians; who, as well as their coloniſts the Carthaginians, ſpoke a dialect of the Hebrew ſcarcely varying from the original.

The Coptic, or Egyptian, reſembles the Greek in moſt of its characters, and is therefore to be referred to the ſame original.

The Chaldee, Syriac, and latter Samaritan, are dialects of the Hebrew, without any conſiderable deviation, or many additional words.

The Ethiopic differs more from the Hebrew, but leſs than the Arabic; yet theſe languages have all iſſued from the ſame ſtock, as the ſimilarity of their formation, and the numberleſs words common to them, ſufficiently evince. The Perſic is very nearly allied to the Arabic.

It appears that all the languages in uſe amongſt men that have been conveyed in alphabetical characters, have been the languages of people connected ultimately or immediately with the Hebrews, who have handed down the earlieſt ſpecimens of writing to poſterity; and we have therefore the greateſt reaſon to believe, that their method of writing, as well as their language, was derived from the ſame ſource.

All the alphabets in the world cannot be derived from one original; becauſe there is a variety of alphabets uſed in different parts of Aſia, which vary in name, number, figure, order and power, from the Phœnician, ancient Hebrew, or Samaritan. In ſeveral of theſe alphabets alſo there are marks for ſounds peculiar to the language of the eaſt, which are not neceſſary to be employed in the notation of the languages of Europe.

None of the alphabets to the eaſt of Perſia have any connection with the Phœnician or its derivatives, except where the Arabic letters have been introduced by the conqueſts of the Mahometans.

The foundation of all the Indian characters are thoſe called *ſhanſcrit*, or *ſungſkrit*, which ſignifies ſomething brought to perfection, in contradiſtinction to *prakrit*, which ſignifies vulgar or unpoliſhed. Hence the refined and religious language and characters of India are called *Sungſkrit*, and the more vulgar mode of writing and expreſſion *Prakrit*. From the Shanſcrit are derived the ſacred characters of Thibet, the Caſhmirian, Bengaleſe, Malabaric, and Tamoul; the Singaleſe, Siameſe, Maharattan, Concanee, &c.

From the ſame ſource we may derive the Tangutic or Tartar characters, which are ſimilar, in their great outlines, to the Shanſcrit; though it is not eaſily determined which is derived from the other. The common Tartar is generally read, like the Chineſe, from top to bottom.

There are, however, ſeveral alphabets uſed in different parts of Aſia, entirely different, not only from the Shanſcrit and all thoſe derived from it, but alſo from the Phœnician and thoſe which proceed from it. Some of which are the alphabet of Pegu, the *Batta* characters uſed in the iſland of Sumatra, and the *Barman* or *Boman* characters uſed in ſome parts of Pegu.

The names and powers of the letters of which theſe alphabets are compoſed differ entirely from the Phœnician, or thoſe derived from them. It is impoſſible to aſſimilate their forms, and indeed it is by no means eaſy to conceive how the 50 letters of the Shanſcrit language could be derived from the Phœnician alphabet, which conſiſted originally only of 13; though it is certain, that by far the greater number of alphabets now in uſe are derived from the ancient Hebrew, Phœnician, or Samaritan.

From the ancient Hebrew proceeded the Chaidal, or ſquare Hebrew; the round Hebrew; and what is called the *running hand of Rabbins*.

The Pelaſgian gave birth to the Etruſcan, Eugubian, or Umbrian, Oſcan, Samnite, and Ionic Greek, written from the left.

From the Chaldaic, or ſquare Hebrew, are derived the Syriac, and the antient and modern Arabic.

The Syriac is divided into the Eſtrangelo and Mendæan, and the modern Arabic has given riſe to the Perſian and Turkiſh.

From the ancient Arabic are derived the Kufic or Oriental, the Mauritanic or Occidental; the African or Saracen, and the Mooriſh.

The Ionic Greek gave riſe to the Arcadian, Latin, ancient Gauliſh, ancient Spaniſh, ancient Gothic, Coptic, Ethiopic, Ruſſian, Illynian or Sclavonic, Bulgarian and Armenian.

From the Roman are derived the Lombardic, Viſigothic, Saxon, Gallican, Franco-Gallic or Merovingian, German, Caroline, Capetian, and modern Gothic.

The Punic letters are ſometimes called Tyrian, and were much the ſame with the Carthaginian or Sicilian. The Punic language was at firſt the ſame with the Phœnician; it is nearly allied to the Hebrew, and has an affinity with the Chaldee and Syriac. Some remains of it are to be met with in the Malteſe.

The Pelaſgi were likewiſe of Phœnician original; and, according to Sanconiatho, the Dioſcuri and Cabiri wrote the firſt annals of the Phœnician hiſtory, by order of Taaut the inventor of letters.

They made ſhips of burthen, and being caſt upon the coaſt near mount Caſius, about 40 miles from Peluſium, where they built a temple in the ſecond generation after the deluge related by Moſes, they were called *Pelaſgi* from their paſſing by ſea, and wandering from one country to another.

Herodotus informs us, that the Pelaſgi were deſcendants of the Phœnician Cabiri, and that the Samothracians received and practiſed the Cabiric myſteries from them.

The Pelaſgic alphabet prevailed in Greece till the time of Deucalion, when the Pelaſgi were driven out of Theſſaly or Oenotria by the Hellenes; after which ſome of them ſettled at the mouth of the Po, and others at Croton, now Cartona in Tuſcany.

Their alphabet conſiſted of 16 letters, and the Tyrrhenian alphabet, brought into Italy before the reign of that prince, conſiſted of no more than 13.

Deucalion is ſaid to have reigned about 820 years after the deluge, and 1529 before the Chriſtian æra.

That the Tyrrheni, Tyrſeni, or Hetruſci, ſettled in Italy long before this period, appears from the teſtimony of Herodotus, who informs us, that a colony went by ſea from Lydia into Italy under Tyrrhenus; and Dionyſius of Halicarnaſſus proves that many authors called them Pelaſgi. He then cites Hellanicus Leſbicus, an author ſomewhat more ancient than Herodotus, to prove, that they were firſt called *Pelaſgi Tyrrheni*; and when they paſſed into Italy, they ſettled in that part of it called *Etruria*.

Their emigration took place about the year of the world 2011, or 1993 years before the Chriſtian æra, which is 350 years before the Pelaſgi left Greece. Several Roman authors alſo ſpeak of this Lydian colony; and Horace compliments his patron Mæcenas upon his Lydian deſcent:

Lydorum quicquid Etruſcos
Incoluit fines, nemo generoſior eſt te.

The Etruſcan letters are Pelaſgic, and ſeveral of the Etruſcan inſcriptions are written in the Pelaſgic language.

The Roman letters are Ionic. The Oſcan language was a dialect of the Etruſcan; their characters are nearer the Ionic or Roman than the Etruſcan. There is alſo very little difference between the Pelaſgian, Etruſcan, and moſt antient Greek letters, which are placed from right to left.

The Arcadians were ancient Greeks, and uſed the Ionic letters; but at what time they began to write from left to right is not known, as their chronology is very uncertain.

The Etruſcan, Oſcan, and Samnite alphabets, are derived from the Pelaſgic; they differ from each other more in name than in form, but a far greater number are derived from the Ionic Greek; viz. the Arcadian, the Latin or Roman, and the others already enumerated. The Runic is derived from the Gothic.

According to Dionyſius of Halicarnaſſus, the firſt Greek colony which came into Italy conſiſted of Arcadians under the conduct of Oenotrus the ſon of Lycaon, and fifth in deſcent from Phoroneus the firſt king of Argos, who reigned about 566 years before the taking of Troy, and 1750 years before the Chriſtian æra.

Theſe Oenotrians were called Aborigines; and after they had been engaged for many years in a war with the Siculi, entered into an alliance with a colony of the Pelaſgi, who came out of Theſſaly into Italy, after having been driven from the former country. About 1476 B. C. another colony of the Pelaſgi, who had been driven out of Theſſaly by the Coretes and Leleges, arrived in Italy, where they aſſiſted the Aborigines to drive out the Siculi; poſſeſſing themſelves of the greateſt part of the country between the Tiber and Liris, and building ſeveral cities.

Solinus and Pliny tell us, that the Pelaſgi firſt carried letters into Italy; and the latter diſtinguiſhes between the Pelaſgi and the Arcades: ſo the letters firſt carried into Italy were not the Ionic Greek, but thoſe more ancient Pelaſgi characters, which the Pelaſgi carried with them before Deucalion and Cadmus are ſaid to have come into Bœotia and Theſſaly.

The ſtory of Cadmus is much involved in fable; but it is agreed by moſt of the ancients, that the children of Agenor, viz. Cadmus, Europa, Phœnix, and Cilix, carried with them a colony, compoſed of Phœnicians and Syrians, into Aſia Minor, Crete, Greece, and Lybia, where they introduced letters, muſic, poetry, and other arts, ſciences, and cuſtoms, of the Phœnicians.

Dionyſius enumerates the following Greek colonies which came into Italy: 1. The Aborigines under Oenotrus from Arcadia. 2. The Pelaſgic colony which came from Hœmonia or Theſſaly. 3. Another Arcadian colony, which came with Evander from Pallantium. 4. Thoſe who came from Peloponneſus with Hercules; and, 5. Thoſe who came with Æneas from Troy.

It is not eaſy to diſcover when the Ionic way of writing from left to right was introduced into Italy; but it is certain, that it did not univerſally prevail even in Greece till ſeveral ages after it was found out.

The Athenians did not comply with it till the year of Rome 350; nor was it practiſed by the Samnites even in the ſixth century of that city, or 230 years before Chriſt: for M. Gæbelin, Vol. VI. pl. 2. gives us the Samnite alphabet of that century, wherein the letters are placed from right to left; although the Ionic way of writing prevailed in ſome parts of Italy in the third century of Rome. "In time, ſays Pliny, the tacit conſent of all nations agreed to uſe the Ionic letters. The Romans conſented to this mode about the time of Tarquinius Priſcus their fifth king."

After the Romans had eſtabliſhed the uſe of the Ionic letters, they ſeem not to have acknowledged the Pelaſgian and Etruſcan to have been Greek alphabets: the moſt learned of them knew none older than the Ionic, as appears from the Greek Farneſe inſcriptions of Herodes Atticus.

The ancient Gauliſh letters are derived from the Greek, and their writing approaches more nearly to the Gothic than that of the Romans: this appears by the monumental inſcription of Gordian, meſſenger of the Gauls, who ſuffered martyrdom in the third century with all his family. The Gauliſh characters were generally uſed by that people before the conqueſt of Gaul by Cæſar; but after that time the Roman letters were gradually introduced.

The ancient Spaniards uſed letters nearly Greek before their intercourſe with the Romans.

The ancient Gothic alphabet was very ſimilar to the Greek, and is attributed to Ulphilas, biſhop of the Goths, who lived in Mæſia about 370 years after Chriſt. He tranſlated the bible into the Gothic tongue. This circumſtance might have occaſioned the tradition of his having invented theſe letters; but it is probable that theſe characters were in uſe long before this time.

The Runic alphabet is derived from the ancient Gothic.

The Coptic letters are derived immediately from the Greek. Some have confounded them with the ancient Egyptian; but there is a very material difference between them. The Ethiopic alphabet is derived from the Coptic.

The alphabet proceeding from that of the Scythians, eſtabliſhed in Europe, is the ſame with what St. Cyril calls the *Servien*.

The Ruſſian, Illyrian or Sclavonic, and the Bulgarian, are all derived from the Greek.

The Armenian letters differ very much from the Greek, from which they are derived, as well as from the Latin.

With regard to the alphabets derived from the Latin, the Lombardic relates to the manuſcripts of Italy; the Viſigothic to thoſe of Spain; the Saxon to thoſe of England; the Gallican and Franco-Gallic or Merovingian to the manuſcripts of France; the German to thoſe of that country; and the Caroline, Capetian, and Modern Gothic, to all the countries of Europe who read Latin.

The firſt ſix of theſe alphabets are before the age of Charlemagne, the laſt three poſterior to it.

They are more diſtinguiſhed by their names than the forms of their characters, and the former indicate all of them to have been of Roman extractions.

The Viſigoths introduced their form of writing into Spain, after having over-run that country; but it was aboliſhed in a provincial ſynod held at Leon in 1091, when the Latin characters were eſtabliſhed for all public inſtruments, though the Viſigothic were uſed in private writings, for three centuries afterwards.

The Gauls, on being ſubjected by the Romans, adopted their manner of writing; but by ſubſequent additions of their own, their characters were changed into what is called the Gallican or *Roman Gallic* mode. This was changed by the Franks into the *Franco-Gallic* or *Merovingian* mode of writing, being practiſed under the kings of the Merovingian race. It took place towards the cloſe of the ſixth century, and continued till the beginning of the ninth.

The German mode of writing was improved by Charlemagne, and this improvement occaſioned another diſtinction in writing by introducing the alphabet named Caroline, which declined in the 12th century, and was ſucceeded in the 13th by the modern Gothic. In France it had degenerated by the middle of the 10th century, but was reſtored in 987 by Hugh Capet, whence it obtained the name of Capetian. It was uſed in England as well as Germany and France.

The modern Gothic, which ſpread itſelf all over Europe in the 12th and 13th centuries, is improperly named, as not deriving its origin from the writing anciently uſed by the Goths. It is, however, the worſt and moſt barbarous way of writing, and originated among the ſchoolmen in the decline of the arts; being indeed nothing elſe than Latin writing degenerated. It began in the 12th century, and was in general uſe, eſpecially among monks and ſchoolmen, in all parts of Europe, till the reſtoration of arts in the 15th century, and continued longer in Germany and the northern nations. Our ſtatute-books are ſtill printed in Gothic letters.

The idea that all the alphabets now mentioned are derived from the Roman, tends to prove the diſtinction of national writing, and is of great uſe in diſcovering the age of manuſcripts: for though we may not be able exactly to determine the time when a manuſcript was written, we may be able nearly to aſcertain its age.

The learned author of Hermes informs us, that to about 20 plain elementary ſounds, we owe that variety of articulate voices which have been ſufficient to explain the ſentiments of ſuch an innumerable multitude as all the paſt and preſent generations of men. Mr. Sheridan ſays, that the number of ſimple ſounds in our tongue are 28; while Dr. Kenrick aſſerts, that we have only 11 diſtinct ſpecies of articulate ſounds, which, even by contraction, prolongation, and compoſition, are increaſed only to the number of 16; every ſyllable or articulate ſound in our language being one of the number. Biſhop Wilkins, and Dr. William Holder ſpeak of 33 ſounds. But the late ingenious and learned John Herries, M. A. has given an elegant ſcale, wherein he proves, that there are exactly 29 ſounds in the Engliſh language.

After the analyſis or decompoſition of language into the elementary ſounds, the next ſtep towards the notation of it by alphabetical characters, would be the delineation of a ſeparate mark ot letter to repreſent each ſound; which marks, though few in number, would admit of ſuch a variety of arrangements and combinations, as might be capable of producing that infinity of articulate ſounds which compoſe the language.

The very numerous combinations of the twenty-four letters, even without any repetition, amount to no fewer than 620,448,401,733,239,439,360,000; and much more than ſufficient to expreſs all the ſounds that ever were articulated by man.

As there are more ſounds in ſome languages than in others, it follows of courſe, that the number of elementary characters, or letters, muſt vary in the alphabets of different languages.

ALPHÆNIX, white barley-ſugar, to which is given an extraordinary name, to render it more valuable. This ſugar, which is thought good for colds, is made of common ſugar, which is boiled until it becomes eaſy to crack, when they pour it upon a marble table, greaſed with oil of ſweet almonds, and mould it into various figures with a braſs crotchet.

ALPHERATZ, in aſtronomy, a fixed ſtar of the third magnitude in Aquarius.

ALPHESERA, in botany, a ſynonime of the plant bryony.

ALPHESTES, in ichthyology, a name given by Geſner to the cinædus.

ALPHETA, in aſtronomy, a fixed ſtar in the lucida coronæ.

ALPHITIDON, in ſurgery, a ſpecies of fracture, by which the bone is broke into a great number of ſmall parts.

ALPHONSIN, in ſurgery, an inſtrument for extracting bullets from gun-ſhot wounds. This inſtrument derives its name from the inventor, Alphonſus Ferrier, a phyſician of Naples. It conſiſts of three branches, which are cloſed by a ring. When cloſed and introduced into the wound, the operator draws back the ring towards the handle, upon which the branches opening take hold of the ball, and then the ring is puſhed from the haft, by which means the branches graſp the ball ſo firmly, as to extract it from the wound.

ALPHOS, in medicine, implies a white or black ſcurf, like ſcales, on the ſkin; which commonly proceeds from a ſcorbutic habit.

ALPINIA, in botany, a genus of the monogynia order, belonging to the monandria claſs of plants; and in the natural method ranking under the ſame order, Scitamineæ. For the characters ſee Syſtem of BOTANY. Of this genus there is but one ſpecies, which is a native of the Weſt Indies, where it grows naturally in moiſt places. The leaves decay every winter, and are puſhed out from the roots in the ſpring, like the ginger and maranta; ſo muſt be managed in the ſame manner as directed for theſe two plants, and may be propagated by parting the roots when the leaves decay.

ALPISTE, or ALPIA, a ſort of ſeed uſed to feed birds with, eſpecially when they are to be nouriſhed for breeding. The Alpiſte ſeed is of an oval figure, of a pale yellow, inclining to an iſabel colour, bright and gloſſy. It is an article of the cornchandlers and ſeedſmens trade.

ALQUIER, a liquid meaſure, uſed in Portugal to meaſure oil, two of which make an almond.

ALQUIFOU, or ARQUIFOU, is a ſort of lead-ore, which, when broken, looks like antimony. It is uſed by the potters to give a green varniſh to their works, and thence is called potter's ore. It is met with in Cornwall, &c. The potters mix a ſmall portion of manganeſe with the alquifou, and then the varniſh or glazing on their ware is of a blackiſh hue.

ALRAMECH, or ARAMECH, a name given to Arcturus by the Arabic aſtronomy.

ALRAUPE, in ichthyology, a ſynonime of the gadus.

ALRUKAK, in the art of medicine, a ſpecies of frankincenſe.

ALRUM, in botany, a name given to the tree which produces the bdellium.

ALSAHARATICA, in botany, a ſynonime of the herb feverfew.

ALSCNEFU, in botany, a ſynonime of the herb wormwood.

ALSEBON, in chemiſtry, ſignifies ſea ſalt.

ALSIMEL, in medicine, a ſynonime of the Indian ſpikenard.

ALSINA, in botany, a ſynonime of the theligonum.

ALSINASTRUM, in botany, the trivial name and alſo a ſynonime of the elatine.

ALSINE, or Chickweed, a genus of the trigynia order, belonging to the pentandria claſs of plants; and, in the natural method, ranking under the 22d order, Caryophyllei. For the characters, ſee Syſtem of Botany. Of this genus a great number of ſpecies are enumerated by botanical writers; but none of them poſſeſs any remarkable properties, except the media, or common chickweed, with white bloſſoms, which is ſo well known as to need no particular deſcription.

This ſpecies affords a ſtriking inſtance of what is called the *ſleep of plants:* for, every night, the leaves approach in pairs, ſo as to include within their upper ſurfaces the tender rudiments of the new ſhoots; and the uppermoſt pair but one at the end of the ſtalk are furniſhed with longer leaf-ſtalks than the others; ſo that they can cloſe upon the terminating pair, and protect the end of the branch.

The young ſhoots and leaves, when boiled, can hardly be diſtinguiſhed from ſpring ſpinach. They are deemed refrigerating and nutritive, and an excellent food for perſons of a conſumptive habit of body.

ALSTONIA, in botany, a genus of the monogynia order, belonging to the hexandria claſs of plants. For the characters, ſee Syſtem of Botany. There is but one ſpecies, the theaformis, a native of America.

ALSTROEMERIA, in botany, a genus of the monogynia order, belonging to the hexandria claſs of plants; and, in the natural method, ranking under the 11th order, Sarmentaceæ. For its characters, ſee Syſtem of Botany. There are five ſpecies, natives of Italy and Peru.

ALT, in muſic, a term applied to the high notes in the ſcale.

ALTAIC Chain, a range of mountains which bounds Aſia on the ſouth.

ALTAR, a place upon which ſacrifices were anciently offered to ſome deity.

The heathens at firſt made their altars only of turf; afterwards they were made of ſtone, of marble, of wood, and even of horn, as that of Apollo in Delos.

Altars differed in figure as well as in materials. Some were round, others ſquare, and others triangular. All of them were turned towards the eaſt, and ſtood lower than the ſtatues of the gods; and were generally adorned with ſculpture, repreſenting either the gods to whom they were erected, or their ſymbols.

The height of their altars differed according to the various gods to whom they ſacrificed.

According to Servius, thoſe altars, ſet apart for the honour of the celeſtial gods, were placed on a tall pile of building; and for that reaſon were called *altaria*, from the words *alta* and *ara*, " a high elevated altar."

Thoſe appointed for the terreſtrial gods were laid on the ſurface of the earth, and called *aræ*.

And, on the contrary, they dug into the earth and opened a pit for thoſe of the infernal gods, which they called βοθροι λακκοι, ſcrobiculi. But this diſtinction is not generally obſerved: the beſt authors frequently uſe *ara* as a general word, under which are included the altars of the celeſtial and terreſtrial, as well as thoſe of the infernal gods. Witneſs Virgil, En. 12. v. 201.

> *Tango aras, medioſque ignes, & numina teſtor,*
> *Nulla dies pacem hanc Italis, nec fœdera rumpet.*
>
> " I touch the ſacred altars, touch the flames,
> " And all thoſe powers atteſt, and all their names;
> " Whatever chance befel on either ſide,
> " No term of time this union ſhall divide."

Where *aræ* plainly includes *altaria*; for whatever we make of Daphnis, Phœbus was certainly a celeſtial god. So Cicero, pro Quint. *Aras delubraque Hecates in Græcia vidimus.*

The Greeks alſo diſtinguiſhed two ſorts of altars; that whereon they ſacrificed to the gods was called βωμος, and was a real altar, different from the other whereon they ſacrificed to the heroes, which was ſmaller, and called εσχαρα.

Pollux makes this diſtinction of altars in his Onomaſticon; he adds, however, that ſome poets uſed the word εσχαρα for the altar whereon ſacrifice was offered to the gods.

The Septuagint verſion does ſometimes alſo uſe the word εσχαρα, for a ſort of little low altar, which may be expreſſed in Latin by *craticula*; which implies a hearth rather than an altar.

Before temples were in uſe, altars were erected in groves, highways, and on the tops of mountains; and the name, enſign, or character, of the deity to whom they were conſecrated, engraved on the front or face of them.

In the great temples of ancient Rome there were ordinarily three altars: The firſt was placed in the ſanctuary, at the foot of the ſtatue of the divinity, upon which incenſe was burnt and libations offered; the ſecond was before the gate of the temple, upon which they ſacrificed the victims; and the third was a portable altar, upon which were placed the offering and the ſacred veſſels.

Beſides theſe uſes of altars, the ancients ſwore upon them, and ſwore by them, in making alliances, confirming treaties of peace, and other ſolemn occaſions. Altars alſo ſerved as places of refuge to all thoſe who fled to them, for whatever crime they might have committed.

Altars are doubtleſs as ancient as ſacrifices themſelves; conſequently their origin is not much later than that of the world.

Altars, in the patriarchal times, were very rude. The altar which Jacob ſet up at Beth-el was nothing but a ſtone, which ſerved him inſtead of a bolſter; that of Gideon, a ſtone before his houſe: and the firſt which God commanded Moſes to erect was probably of earth, or unpoliſhed ſtones, without any iron; for if any uſe was made of that metal, the altar was declared impure.

The principal altars of the Jews were, The altar of *incenſe*; that of *burnt-offering*; and the *altar*, or *table, for the ſhew-bread*.

The *altar of incenſe* was a ſmall table of ſhittim-wood, covered with plates of gold, of one cubit in length, another in width, and two in height. At the four corners, were four kinds of horns, and all round a little border or crown over it.

This was the altar hidden by Jeremiah before the captivity; and upon it the officiating prieſt offered, every morning and evening, incenſe of a particular compoſition.

The *altar of burnt offerings* was made of ſhittim-wood, and carried upon the ſhoulder of the prieſts by ſtaves of the ſame wood overlaid with braſs.

In the time of Moſes, this altar was five cubits ſquare and three high; but in Solomon's temple it was much larger, being 20 cubits ſquare and 10 in height. It was covered with braſs; and at each corner was a horn or ſpire, wrought out of the ſame wood with the altar, to which the ſacrifices were tied. Within the hollow was a grate of braſs, on which the fire was made; through it fell the aſhes, and were received in a pan below. At the four corners of the grate were four rings and four chains, which kept it up at the horns. This altar was placed in the open air, that the ſmoke of the burnt-offerings might not ſully the inſide of the tabernacle.

The *altar*, or *table*, for the *ſhew-bread*, was likewiſe of ſhittim-wood, covered with plates of gold, having a little border round it, adorned with ſculpture. It was two cubits long, one wide, and one and an half in height. Upon this table, which ſtood in the holy of holies, were put every ſabbath-day, 12 loaves, with ſalt and incenſe.

The Jewiſh altars, after their return from the captivity, and the building of the ſecond temple, were in ſome reſpects different from thoſe deſcribed above. That of burnt-offerings was a large pile, built of unhewn ſtone, 32 cubits ſquare at the bottom, and 24 ſquare at the top. The aſcent was by a gentle riſing, 32 cubits in length, and 16 in breadth.

Altar is alſo uſed among Chriſtians for the communion-table.

In the primitive church, the altars were only of wood; as being frequently to be removed from place to place. But the council of Paris, in 509, decreed that no altar ſhould be built but of ſtone. At firſt there was but one altar in each church; but the number ſoon increaſed; and from the writings of Gregory the Great, who lived in the ſixth century, we learn, that there were ſometimes in the ſame church 12 or 13.

In the cathedral of Magdeburg there are no leſs than 49 altars.

The altar is ſometimes ſuſtained on a ſingle column, as in the ſubterraneous chaples of St. Cecilia, at Rome, &c. and ſometimes by four columns, as the altar of St. Sebaſtian of Crypta Arenaria; but the cuſtomary form is, to be a maſſive of ſtone-work, ſuſtaining the altar-table.

Theſe altars bear a reſemblance to tombs: to this purpoſe, we read in church hiſtory, that the primitive Chriſtians chiefly held their meeting at the tombs of the martyrs, and celebrated the myſteries of religion upon them; for which reaſon, it is a ſtanding rule to this day in the church of Rome never to build an altar, without incloſing the relics of ſome ſaint in it.

ALTAR Thane, or Altariſt, in old law-books, an appellation given to the prieſt or parſon of a pariſh, to whom the the altarage belonged.

ALTARAGE, in law, altars erected in virtue of donations, before the Reformation, within a parochial church, for the purpoſe of ſinging of maſs for deceaſed friends.

Altarage likewiſe ſignifies the profits ariſing to the prieſt on account of the altar.

ALTARIST, in eccleſiaſtical hiſtory, denotes the vicar of a church: figuratively implying, that the altar procured him a livelihood. The word is uſed in modern church hiſtory for a chaplain.

ALTASRIF, in medical hiſtory, denotes the fundamentals of the Arabian principles of the art of healing.

ALTAVELA, in ichthyology, ſignifies a particular ſpecies of the aquila marina kind, common in the markets of the Mediterranean, and very good for food.

ALTERANTS, or ALTERATIVE *Medicines*, ſuch as correct the bad qualities of the blood and other humours, without occaſioning any ſenſible evacuation.

ALTERATION, in phyſics, the act of changing the circumſtances and manner of a thing; its general nature and appearance remaining the ſame. Or, an accidental and partial change in a body; without proceeding ſo far as to make the ſubject quite unknown, or to take a new denomination thereupon. By this *alteration* is diſtinguiſhed from *generation* and *corruption*; thoſe terms expreſſing an acquiſition or loſs of the eſſential qualities of a thing.

ALTERCATION, a debate or conteſt between two friends or acquaintance. The word comes from *altercari*, which anciently ſignified, to converſe, or hold diſcourſe together.

ALTERN-BASE, in trigonometry, a term uſed in contradiſtinction to the true baſe. Thus in oblique triangles, the true baſe is either the ſum of the ſides, and then the *difference* of the ſides is called the *altern-baſe*; or the true baſe is the difference of the ſides, and then the *ſum* of the ſides is called the *altern-baſe*.

ALTERNATE, in a general ſenſe, a term applied to ſuch perſons or things as ſucceed each other by turns.

ALTERNATE, in heraldry, is ſaid in reſpect of the ſituation of the quarters. Thus the firſt and fourth quarters, and the ſecond and third, are uſually of the ſame nature, and are called *alternate quarters*.

ALTERNATE, in botany, ſignifies when the leaves or branches of plants ariſe higher on oppoſite ſides alternately.

ALTERNATION, in its primary ſenſe, denotes a ſucceſſion by turns.

ALTERNATION is ſometimes uſed to expreſs the different changes or alterations of orders in any number of things propoſed; which is alſo called *permutation*, and eaſily found by continual multiplication of all the numbers, beginning at unity.

ALTERNATIVE is particularly uſed for the choice of two things propoſed. In this ſenſe we ſay, to take the *alternative* of two propoſitions.

ALTHÆA, MARSHMALLOW, a genus of the polyandria order, belonging to the monodelphia claſs of plants; and, in the natural method, ranking under the 37th order, *Columniferæ*. For the characters, ſee Syſtem of BOTANY. There are three ſpecies of this plant, viz.

1. The vulgaris, or common marſhmallow, a native of Britain; it is a perennial plant, and has an annual ſtalk, which periſhes every autumn. 2. The hirſuta, or hairy marſhmallow, is a native of Spain and Portugal. 3. The cannabina, or ſhrubby marſhmallow, is a native of Hungary and Iſtria. Though the firſt ſort is found naturally in ſalt marſhes, it will thrive when tranſplanted into any ſoil, or in any ſituation; however, it will always grow larger in moiſt than in dry ſoil. If the ſeeds of the ſecond ſpecies are ſown in April, the plants will flower in July, and carry ripe ſeed in September. The ſeeds of the cannabina ought alſo to be ſown where the plants are to remain, and have a ſheltered ſituation and a dry ſoil, otherwiſe they will not live through the winter.

The hirſuta, or hairy marſhmallow, is the only ſpecies uſed in medicine. The whole plant, eſpecially the root, abounds with a mild mucilage. It has the general virtues of an emollient medicine; and proves ſerviceable in a thin acrimonious ſtate of the juices, and where the natural mucus of the inteſtines is abraded. It is chiefly recommended in ſharp defluxions upon the lungs, hoarſeneſs, dyſenteries; and likewiſe in nephritic and calculous complaints; not, as ſome have ſuppoſed, that this medicine has any peculiar power of diſſolving or expelling the calculous; but as, by lubricating and relaxing the veſſels, it procures a more free and eaſy paſſage. The root is ſometimes employed externally for ſoftning and maturating hard tumours; chewed, it is ſaid to give eaſe in difficult dentition of children.

This root gave name to an officinal ſyrup, decoction, and ointment; and was likewiſe an ingredient in the compound powder of gum tragacanth, and the oil and plaſter of mucilages. But of all theſe formulæ the ſyrup alone is now retained.

ALTIMETRY, the art of meaſuring altitudes or heights, whether acceſſible or inacceſſible.

ALTIN, a money of account in Muſcovy, worth three *copecs*; one hundred of which make a ruble, worth about 4s. 6d. ſterling.

ALTINCAR, among mineraliſts, a ſpecies of factitious ſalt uſed in the fuſion and purification of metals.

It is a ſort of flux powder, and divers ways of preparing it are given by Libavius.

ALTITUDE, in a general ſenſe, implies, height or diſtance from the ground meaſured upward.

The method of taking conſiderable terreſtrial altitudes, of which thoſe of mountains are the greateſt, by means of the barometer, is very eaſy and expeditious. It is done by obſerving, on the top of the mountain, how much the mercury has fallen below what it was at the foot of the mountain.

ALTITUDE *of the Eye*, in perſpective, is a right line let fall from the eye, perpendicular to the geometrical plane.

ALTITUDE, in aſtronomy, is the diſtance of a ſtar, or other point, in the mundane ſphere, from the horizon.

This altitude may be either *true* or *apparent*. If it be taken from the rational or real horizon, the altitude is ſaid to be true or real; if from the apparent or ſenſible horizon, the altitude is apparent. Or rather, the apparent altitude is ſuch as it appears to our obſervation; and the *true* is that from which the refraction has been ſubtracted.

The true altitudes of the ſun, fixed ſtars, and planets, differ but very little from the apparent altitudes; becauſe of their great diſtance from the centre of the earth, and the ſmallneſs of the earth's ſemidiameter, when compared thereto. But the difference between the true and apparent altitude of the moon is about 52′.

ALTITUDE *Inſtrument*, or *Equal Altitude Inſtrument*, is that uſed to obſerve a celeſtial object when it has the ſame altitude on the eaſt and weſt ſides of the meridian.

ALTO *et Baſſo*, or *in Alto & in Baſſo*, in law, ſignifies the abſolute reference of all differences, ſmall and great, high and low, to ſome arbitrator or indifferent perſon.

ALTO *Relievo*, ſynonimous with RELIEVO.

ALTO *Ripieno*, in muſic, the tenor of the grand chorus which ſings and plays only now and then in ſome particular places.

ALTOLIZOIM, in chemiſtry, denotes the latum paracelſi, reduced to an oil, ſometimes called fel terræ, or bitter ſalt.

ALTUMAL, in commerce, a low method of phraſeology, to communicate crafty dealings to perſons of the ſame trade.

ALVAH, ſuppoſed by ſome to be the name of the wood wherewith Moſes ſweetened the waters of Marah, Exod. ch. xv. ver. 25. The name of this wood is not found in Scripture; but the Mahometans give it that of *alvah*, and pretend to trace its hiſtory from the patriarchs before the flood. Joſephus, on the contrary, ſays, that Moſes uſed the wood which he found next lying before him.

ALVARID, in antient hiſtory, ſignifies the ſame as of the preſent Spaniſh magiſtracy called Alcaida.

ALVARISTS, in church hiſtory, a ſectuary of religious profeſſors, partly Jeſuits and partly Janſeniſts.

ALUCITÆ, in entomology, a ſubdiviſion in the Linnæan ſyſtem of the genus of phalæna, or nocturnal butterflies, comprizing eight ſpecies.

ALUCO, in ornithology, a ſynonime of the church or white owl.

ALUDELS, in chemiſtry, earthen pots without bottoms, inſerted into each other, and uſed in ſublimations.

ALVEARIUM, in anatomy, the bottom of the concha or hollow of the outer ear.

ALVEARIUM alſo ſignifies a bee-hive. The word is formed of *alveus*, a channel or cavity; in alluſion to the *alveoli*, or cells in bee-hives.

Some of the ancients uſe alſo the word *alvearium* for a bee-houſe, more uſually called among us *apiary*.

ALVEARIUM is ſometimes alſo uſed figuratively, to denote a collection. In which ſenſe, *alvearium* amounts to much the ſame with what we otherwiſe call *theſaurus, cornucopia*, or the like.

ALVEOLI, or ALVEOLUS, in anatomy, the ſockets wherein the teeth are ſet in the jaw. See Syſtem of ANATOMY.

ALVEOLI, in natural hiſtory, implies the holes wherein bees depoſit their honey in the combs.

ALUESEN, in botany, a ſynonime of hogs fennel.

ALVEOLUS, in natural hiſtory, the name of the waxen cells in bee-hives. Alſo the name of a ſea-foſſil of a conic figure, compoſed of a number of cells, like bee-hives, joined into each other, with a pipe of communication.

ALVEUS, is a general word for any channel wherein a liquid can flow: and therefore is often met with in the writings of various authors of antiquity, particularly on the ſubjects of Aſtronomy, Anatomy, and Navigation.

In Roman antiquity, we find the legend of Romulus and Remus being expoſed in a ſmall alveus, made of the rind or bark of an elm tree.

ALUM, a clear and tranſparent ſaline matter, uſually ſold in large maſſes, of a very auſtere and aſtringent taſte, uſeful in medicine, and in various arts.

Moſt of the alum to be met with is artificially prepared by chemical operations, though ſometimes a ſmall quantity is produced naturally. This native alum is mixed with heterogeneous matters, or effloreſces in various forms upon the ores during calcination. It rarely occurs in a cryſtallized ſtate, though thus it is ſaid to be met with in Egypt, Sardinia, Spain, Bohemia, and other places. It is alſo found in the waters, impregnated with fixed air, but very ſeldom in fountains or hot medicated waters.

There are ſeveral kinds of alum to be met with; but theſe differ from one another only in being mixed with ſome ſalts which are not of the aluminous kind. That called the Roman alum has been conſidered as preferable to any other. This is uſually met with in ſmall chryſtals, and has a reddiſh colour, moſt probably owing to a ſmall quantity of calx of iron, which, however, does not in the leaſt impair its qualities. The other kinds of alum contain a portion either of vitriolated tartar or ſal ammoniac, according to the nature of the alkali uſed in its preparation.

This ſalt is extremely uſeful in the art of dyeing; as by means of it a great number of colours are fixed and rendered permanent upon cloth, which otherwiſe would either not adhere in any degree, or only for a very ſhort time. It conſtitutes the baſis of crayons, which generally conſiſt of the earth of alum finely powdered and tinged for the purpoſe. In the preparation of Pruſſian blue, it prevents the baſis of martial vitriol, which is ſoluble in acids, from being precipitated by the ſuperfluous alkali employed in the preparation of that pigment; that is, the alkali which is not ſaturated by the colouring matter. As this baſis adheres more ſtrongly than the clay to the vitriolic acid, and would form a green by the mixture of its yellowneſs, the white earth of alum likewiſe, according to its quantity, dilutes the darker colours, even black itſelf, and produces an infinite number of ſhades. It is alſo of uſe in making of candles; for being mixed with the tallow, it gives it an hardneſs and conſiſtence which it has not naturally. Wood or even paper ſufficiently ſoaked in a ſolution of alum does not eaſily take fire, the latter of which is for that reaſon very properly employed in preſerving gun-powder, as it alſo excludes the moiſture of the air. Paper impregnated with alum is uſeful in whitening ſilver, and ſilvering braſs without heat. Alum is alſo of uſe in tanning, where it aſſiſts in reſtoring the coheſion of the ſkins almoſt entirely deſtroyed by the lime.

In medicine it is of conſiderable uſe as an aſtringent and tonic. It is reckoned particularly ſerviceable for reſtraining hemorrhages, and immoderate ſecretions from the blood; but leſs proper in inteſtinal fluxes. In violent hemorrhages, it may be given in doſes of 15 or 20 grains, and repeated every hour or half hour till the bleeding abates: in other caſes ſmaller doſes are more adviſable; large ones being apt to nauſeate the ſtomach, and occaſion violent conſtipations of the bowels.

It is uſed alſo externally, in aſtringent and repellent lotions and collyria. Burnt alum taken internally has been highly extolled in caſes of colic. In ſuch inſtances, when taken to the extent of a ſcruple for a doſe, it has been ſaid gently to move the belly, and give very great relief from the ſevere pain.

Its officinal preparations are, for internal uſe, *pulvis ſtypticus*, and *aqua ſtyptica* for external applications, the *aqua aluminis*, and *coagulum aluminis* and *alumen uſtum*; which laſt is no other than the alum dried by fire, or freed from the watery moiſture, which, like other ſalts, it always retains in its cryſtalline form.

By the loſs of its water it becomes ſharper, ſo as to act as a ſlight eſcharotic: and it is chiefly with this intention that it is employed in medicine, being very rarely taken internally.

The manufacture of alum was firſt invented in the year 1608, and ſucceſſively practiſed in England, meeting with great encouragement in Yorkſhire, where it was firſt made, from Lord Sheffield, and other gentlemen of that county. King James I. by advice of his miniſtry, aſſumed the monopoly of it to himſelf, and therefore prohibited the importation of foreign alum; and in 1625, the importation of it was further prohibited by the proclamation of Charles I.

Alum *Works*, places where alum is prepared, and manufactured in quantities for ſale. They differ from alum-mines, as in the former an artificial alum, and in the latter natural alum, is produced.

ALVIDUCA, in medicine, imply thoſe remedies which are of a laxative or purgative nature.

ALVUS, in anatomy, a term uſed for the belly in general, but more frequently applied to the bowels.

AL-UZZA, in mythology, an ancient Arabian idol, which was demoliſhed by Mahomet in the 8th year of the Hegira.

ALWAIDII, a ſect of Mahometans who believe all great crimes to be unpardonable.

ALYPIAS, or Alypon, among phyſicians, denotes a ſpecies of turbith, uſed as a preſcription for purging the bile.

ALYPUM, a ſynonymous word for dogs-bane, ſpurge and globularia, in botanical deſcriptions of plants.

ALYSSUM, Allyson, or Allysoides, madwort; (from αλυσσω; *to be mad*; becauſe it was believed to have the property of curing madneſs) a genus of the filiculoſa order, belonging to the tetradynamia claſs of plants; and, in the natural method, ranking under the 39th order, *Siliquoſa*. For the characters, ſee Syſtem of Botany.

Of this genus, Linnæus enumerates 19 ſpecies; but none of them are remarkable either for beauty, or any other property, except the halimifolium, or madwort with whole ſpear-ſhaped leaves.

Though theſe plants are natives of the ſouthern parts of Europe; yet, if planted on a dry, lean, or rubbiſhy ſoil, they will endure our ſevereſt winters in the open air. They may alſo be propagated by cuttings, which ought to be planted in April or May, and are very likely to take root, if kept ſhaded in the heat of the day, and gently refreſhed with water.

ALYTARCHA, a prieſt of Antioch in Syria, who, in the games inſtituted in honour of the gods, preſided over the officers who carried rods to clear away the crowd and keep order.

In the Olympic games, the alytarches had the ſame command, and obliged every perſon to preſerve order and decency.

ALZAGIAT, in medical authors, generally imports vitriolic acids.

ALZUM, in botany, implies the tree which produces the bdellium gum; and is a ſynonime of aldum, the proper name of that tree.

AMA, in eccleſiaſtical writers, denotes a veſſel wherein wine, water, or the like, was held, for the ſervice of the euchariſt. In this ſenſe the word is alſo written amula; and frequently hama, and hamula.

Ama is ſometimes alſo uſed for a wine-meaſure, as a caſk, pipe, or the like.

AMABYR, a cuſtom which formerly prevailed in ſeveral parts of England and Wales, being a ſum of money paid to the lord when a maid was married within his lordſhip. The word is old Britiſh, and ſignifies "the price of virginity."

AMADOW, a kind of black-match, tinder, or touch-wood, which comes from Germany. It is made of a ſort of large muſhrooms, or ſpungy excreſcences, which commonly grow on old trees, eſpecially oaks, aſh, and firs. This ſubſtance being boiled in common water, and afterwards dried and well beaten, is then put into a ſtrong lye prepared with ſalt-petre, after which it is again put to dry in an oven. Some give to the amadow the name of *Pyrotechnical Spunge*, becauſe of its aptneſs to take fire.

AMADOWRY, a kind of cotton which comes from Alexandria, by way of Marſeilles.

AMAIN, in the ſea-language, a term importing to lower ſomething at once. Thus to *ſtrike amain*, is to lower, or let fall, the top-ſails; to *wave amain*, is to make a ſignal, by waving a drawn ſword, or the like, as a demand that the enemy ſtrike their top-ſails.

AMALGAM, or Amalga, mercury united with ſome metal.

AMALGAMATION, the operation of making an amalgam, or mixing mercury with any metal.

For the combination of one metal with another, it is generally ſufficient that one of them be in a ſtate of fluidity. Mercury being always fluid, is therefore capable of amalgamation with other metals without heat; nevertheleſs, heat conſiderably facilitates the operation.

To amalgamate without heat requires nothing more than mixing the two metals together in a mortar; but the metal to be united with the mercury ſhould be previouſly divided into very thin plates or grains. When heat is uſed (which is always moſt effectual, and with ſome metals indeſpenſably neceſſary), the mercury ſhould be heated till it begins to ſmoke, and the grains of metal made red-hot before they are thrown into it. If it be gold or ſilver, it is ſufficient to ſtir the fluid with an iron rod for a little while, and then throw it into a veſſel filled with water. This amalgam is uſed for gilding or ſilvering on copper, which is afterwards expoſed to a degree of heat ſufficient to evaporate the mercury.

Amalgamation with lead or tin is effected by pouring an equal weight of mercury into either of theſe metals in a ſtate of fuſion, and ſtiring with an iron rod. Copper amalgamates with great difficulty, and iron not at all.

AMALTHÆA, the name of the Cumæan Sibyl, who offered to Tarquinius Superbus nine books, containing the Roman deſtinies, and demanded 300 pieces of gold for them. He derided her; whereupon ſhe threw three of them into the fire; and returning, aſked the ſame price for the other ſix; which being denied, ſhe burnt three more; and returned, ſtill demanding the ſame price. Upon which Tarquin conſulting the pontifs, was adviſed to buy them. Theſe books were in ſuch eſteem, that two magiſtrates were created to conſult them upon extraordinary occaſions.

Amalthæa, in pagan mythology, the daughter of Meliſſus, king of Crete, and the nurſe of Jupiter, whom ſhe fed with goat's milk and honey. According to others, Amalthæa was a goat which Jupiter tranſlated into the ſky, with her two kids, and gave one of her horns to the daughter of Meliſſus, as a reward for the pains they had taken in attending him. This horn is ſaid to have had the peculiar property of furniſhing them with whatever they wiſhed for; and was thence called the *cornucopia*, or horn of plenty.

The following is a tranſlation of the deſcription given by Ovid of this fiction:

> On Ida's ſummit, in a ſhady grove,
> The Naid Amalthæa foſter'd Jove.
> A goat ſhe had, the faireſt of the ſort;
> Two friſking kids about their mother ſport.
> With lofty wreath'd horns, her temples nod;
> Her dugs were worthy to ſuſtain a God!
> Great Jove ſhe ſuckl'd, of old Rhea born,
> And in the pious office broke her horn;
> As playful in a rifled oak ſhe toſt
> Her heedleſs head, and half its honor's loſt!
> Fair Amalthæa took it off the ground,
> With apples fill'd it, and with garlands bound,

Which to the ſmiling infant ſhe convey'd:
He, when the ſcepter of the gods he ſway'd,
When bold he ſeiz'd his father's vacant throne,
And reign'd the tyrant of the ſkies alone;
Bid his rough nurſe the ſtarry heavens adorn,
And gratefully in the zodiac, fix'd her horn.

AMARANTE, or **Amaranth**, an order of knighthood, inſtituted in Sweden by queen Chriſtina, in 1645, at the cloſe of an annual feaſt, celebrated in that country, called *Wirtſchaft*. This feaſt was ſolemnized with entertainments, balls, maſquerades, and the like diverſions, and continued from evening till the next morning. That princeſs, thinking the name too vulgar, changed it into that of the *feaſt of the gods*, in regard each perſon here repreſented ſome deity as it fell to his lot. The queen aſſumed the name of *Amarante*; that is, unfading, or immortal. The young nobility, dreſſed in the habit of nymphs and ſhepherds, ſerved the gods at the table. At the end of the feaſt, the queen threw off her habit, which was covered with diamonds, leaving it to be pulled in pieces by the maſques; and, in memory of ſo gallant a feaſt, founded a military order, called in Swediſh *geſcilchafft*, into which all that had been preſent at the feaſt were admitted, including 16 lords and as many ladies, beſides the queen. Their device was the cypher of *Amarante*, compoſed of two A's, the one erect, the other inverted, and interwoven together; the whole incloſed by a laurel crown, with this motto, *Dolce nella memoria.*

AMARANTHOIDES, in botany, the trivial name of a ſpecies of illecebrum.

AMARANTHUS, (of α privative, and μαραινω, *to wither*, becauſe the flower of this plant when cropped does not ſoon wither) **Amaranth**, or **Flower-Gentle**, a genus of the pentandria order, belonging to the monœcia claſs of plants; and, in the natural method, ranking under the 54th order, *Miſcelaneæ*. For the charácters, ſee Syſtem of **Botany**.

Of this genus Linnæus enumerates 19 ſpecies; the moſt remarkable of which are. 1. The tricolor, or three-coloured amaranthus. This has been long cultivated in gardens, on account of the beauty of its variegated leaves, which are of three colours, green, yellow, and red; and very elegantly mixed. When the plants are in full vigour, the leaves are large, and cloſely ſet from the bottom to the top of the ſtalks, and the branches form a ſort of pyramid; ſo that there is not a more beautiful plant than this when it is in full luſtre. 2. The melancholicus, bicolor, or two-coloured amaranthus. 3. The caudata, with very long hanging cylindrical ſpikes, a native of America. 4. The maximus, or tree-like amaranthus. 5. The ſanguineus, a native of the Bahama iſlands. It is an eſculent plant, and bears fine flowers. 6. The oleraceus, with obtuſe indented leaves. This has no beauty; but it is uſed by the Indians as a ſubſtitute to cabbage.

The two firſt of theſe ſpecies being tender, require ſome art and care to bring them to perfection in Britain, by a ſucceſſion of hot-beds, with proper waterings, airings, and ſhadings.

AMARYLLIS, **Lily-asphodel**, a genus of the monogynia order, belonging to the hexandria claſs of plants; and, in the natural method, ranking under the 9th order, *Spathaceæ*. For the characters, ſee Syſtem of **Botany**.

The principal ſpecies are, 1. The lutea, or autumnal narciſſus. This is uſually ſold by gardeners, along with colchicums, for autumnal ornaments to gardens. Although there is but one flower in each cover, yet there is a ſucceſſion of flowers from the ſame root, eſpecially when they are ſuffered to remain three or four years unremoved. The roots are bulbous, and ſhaped like thoſe of the narciſſus; ſo are proper ornaments for ſuch borders as are planted with cyclamens, ſaffron, autumnal crocus, colchicums, and ſuch low autumnal flowers. 2. The formoſiſſima, or jacobæa lily, produces its flowers two or three times in a year, without being regular to any ſeaſon. 3. The farnienſis, or Guernſey lily, is ſuppoſed to have come originally from Japan, but has been many years cultivated in the gardens of Guernſey and Jerſey; in both which places they ſeem to thrive as well as if it was their native country, and from theſe iſlands their roots are ſent annually to the curious in moſt parts of Europe. 4. The regina, or belladonna lily, is a native of Portugal. This kind, if properly managed, will ſometimes put out two or three ſtems, growing near three feet high, and produce many flowers in each umbel, which make a fine appearance during the month of October. 5. The zeylanica, or Ceylon lily, is a native of the Weſt Indies, and uſually flowers in June. 6. The Orientalis, or lily daffodil, with leaves ſhaped like a tongue. This is a native of the Cape of Good Hope.

The firſt ſort is very hardy, and will thrive in almoſt any ſoil or ſituation; but will ſucceed beſt in a freſh light dry ſoil, and not too near the dripping of trees, or too near walls. Theſe roots may be tranſplanted any time from May to the end of July; after which it will be too late to remove them. The jacobæa ought to be kept in a moderate ſtove all winter; in which caſe it will ſend forth plenty of offsets, that will produce vigorous plants. The roots of the Guernſey lily are generally brought over in June and July; but the ſooner they are taken out of the ground after the leaves decay, the better: for although the roots which are taken up when their flower-ſtems begin to appear, will flower; yet their flowers will not be ſo large, nor will their roots be near ſo good after, as thoſe which were removed before they ſent forth fibres. The other ſpecies of the amaryllis may eaſily be raiſed by taking care to ſhelter them in a ſtove from the winter's cold.

AMASONIA, in botany, a genus of the angio-ſpermia order, belonging to the didynamia claſs of plants; for the characters ſee Syſtem of **Botany**. The ſeed is an ovate unilocular nut, the length of the calyx.

AMATORII **Musculii**, in anatomy, a term ſometimes uſed for the obliquus ſuperior and obliquus inferior muſcles of the eye, as theſe muſcles aſſiſt in ogling or drawing the eye ſideways.

AMAUROSIS, in medicine, a deprivation of ſight, the eye remaining fair and ſeemingly unaffected. A perfect amauroſis is when the blindneſs is total; when there is ſtill a power of diſtinguiſhing light from darkneſs, the diſeaſe is called by M. de St. Ives an *imperfect amauroſis*. There is a periodical ſort which comes on inſtantaneouſly, continues for hours, or days, and then diſappears. Mr. Hey, ſurgeon at Leeds, mentions ſeveral caſes of patients afflicted with the amauroſis who were relieved by being electrified.

AMAZONS, in antiquity, a nation of female warriors, who founded an empire in Aſia Minor, upon the river Thermodoon, along the coaſts of the Black Sea. They are ſaid to have formed a ſtate out of which men were excluded. What commerce they had with that ſex, was only with ſtrangers; they killed all their male children; and cut off the right breaſts of their females, to make them more fit for the combat. But Dr. Bryant, in his Analyſis of Ancient Mythology, explodes this account as fabulous; and obſerves, that they were in general Cuthite colonies from Egypt and Syria, who formed ſettlements in different countries, and that they derived their name from *zon*, the ſun, which was the national object of worſhip. Vol. iii. p. 463. It has indeed been controverted even among ancient writers, whether ever there really were ſuch a nation as that of the Amazons. Strabo, Palæphatus, and others, deny it. On the contrary, Herodotus, Pauſanius, Diodorus Siculus, Trogus Pompeius, Juſtin, Pliny, Mela, Plutarch, &c. expreſsly aſſert it.

M. Petit, a French phyſician, publiſhed a Latin diſſertation in 1685, to prove that there was really a nation of Amazons; it contains abundance of curious inquiries, relating to their habit, their arms, the cities built by them, &c. Others of the moderns alſo maintain, that their exiſtence is ſufficiently proved by the teſtimony of ſuch of the hiſtorians of antiquity as are moſt worthy of credit; by the monuments which many of them have mentioned; and by medals, ſome of which are ſtill remaining.

We read of Scythian Amazons in Herodotus; of Lybian Amazons, in Diodorus Siculous; and of German Amazons, in Lucius Florus. Later geographers and travellers alſo ſpeak of Mingrelian and Georgian Amazons; Amazons in South America, in Monomotopa, in the Philippine iſlands, in Denmark, &c.

The Amazons of South America lived on the banks of the great river which bears their name, and made the greateſt figure in hiſtory. They are repreſented as having been governed and led to war only by their queen. No men were permitted to live among them; though thoſe of ſome neighbouring nations were ſuffered to viſit them, at a certain ſeaſon, for the ſake of procreation. The females iſſuing from this commerce were bred up with care, and inſtructed in what related to war and government; but the males were ſent away into the country of their fathers.

Some modern geographers and travellers mention Amazons ſtill in being. John de los Sanctos, a Portugueſe Capuchin, in his deſcription of Æthiopia, ſpeaks of a race of Amazons in Africa; Æneas Silvius gives us a very preciſe account of a republic of real Amazons, in Bohemia, which laſted nine years; founded by the courage of a maid named Valaſca.

Amazon is alſo applied, in a figurative ſenſe, to bees, becauſe among thoſe inſects the females alone are commonly ſuppoſed to bear ſway.

M. Warder has publiſhed a work under the title of the True Amazons, or the Commonwealth of **Bees**.

Amazonian *Habit*, in antiquity, denotes a dreſs formed in imitation of the Amazons.

AMAZONIUS, in medicine, ſignifies remedies taken againſt vomiting.

AMBA, an Abyſſinian or Ethiopic word, ſignifying a rock. The Abyſſinians give names to each of their rocks, as *amba-dorho*, the rock of a hen, &c. The moſt remarkableof theſe ocks is called *amba-geſhen*. It is prodigiouſly ſteep, in the form of a caſtle built of free-ſtone, and almoſt impregnable. Its ſummit is about half a Portugueſe league in breadth, and the circumference at the bottom about half a day's journey. The aſcent at firſt is eaſy; but grows afterwards ſo ſteep, that the Abaſſine oxen, which will otherwiſe clamber like goats, muſt be craned up, and let down with ropes. Here the princes of the blood were formerly confined, in low cottages, amongſt ſhrubs and wild cedars, with an allowance barely ſufficient to keep them alive.

Amba, in a botanical ſenſe, implies a ſynonyme of the mango tree.

AMBACHT, in topography, denotes a kind of juriſdiction or territory, the poſſeſſor whereof has the adminiſtration of juſtice, both in *alto* and *baſſo*; or of what is called in the Scots law, a power of pit and gallows; i. e. a power of drowning and hanging. In ſome ancient writers, ambacht is particularly uſed for the chief magiſtracy of a city.

AMBIABA, the name of a tree in Brazil, called by the Indians tipioca.

AMBARVALIA, in antiquity, a ceremony among the Romans, when, in order to procure from the gods an happy harveſt, they conducted the victims thrice round the corn-fields in proceſſion, before ſacrificing them. Ambervalia were either of a private or public nature: the private were performed by the maſter of a family; and the public by the prieſts, who officiated at the ſolemnity, called *fratres ovales*. The prayer preferred on this occaſion, the formula of which we have in Cato, *de Re Ruſtica*, cap. cxlii. was called *carmen ambervale*. At theſe feaſts they ſacrificed to Ceres a ſow, a ſheep, and a bull or heifer, whence they took the name of *ſuovetaurilia*. The method of celebrating them was, to lead a victim round the fields, while the peaſants accompanied it, and one of their number, crowned with oak, hymned forth the praiſes of Ceres, in verſes compoſed on purpoſe. This feſtival was celebrated twice a-year; at the end of January, according to ſome, or in April, according to others; and for the ſecond time, in the month July.

AMBARVALIS Flos, a botanical term for milkwort.

AMBASSADOR, or Embassador, a public miniſter ſent from one ſovereign prince, as a repreſentative of his perſon, to another.

Ambaſſadors are either ordinary or extraordinary. Ambaſſador in ordinary, is he who conſtantly reſides in the court of another prince, to maintain a good underſtanding, and look to the intereſt of his maſter. Till about 200 years ago, ambaſſadors in ordinary were not heard of: all, till then, were ambaſſadors extraordinary; that is, ſuch as are ſent on ſome particular occaſion, and who retire as ſoon as the buſineſs is diſpatched.

By the law of nations, none under the quality of a ſovereign prince can ſend or receive an ambaſſador. At Athens, ambaſſadors mounted the pulpit of the public orators, and there opened their commiſſion, acquainting the people with their errand. At Rome, they were introduced to the ſenate, and delivered their commiſſions to the fathers.

Ambaſſadors ſhould never attend any public ſolemnities, as marriages, funerals, &c. unleſs their maſter have ſome intereſt therein: nor muſt they go into mourning on any occaſions of their own, becauſe they repreſent the perſon of the prince.

By the civil law, the moveable goods of an ambaſſador, which are accounted an acceſſion to his perſon, cannot be ſeized on, neither as a pledge, or for payment of a debt, nor by order or execution of judgment, nor by the king's or ſtate's leave where he reſides, as ſome conceive; for all actions ought to be far from an ambaſſador, as well that which toucheth his neceſſaries, as his perſon: if, therefore, he hath contracted any debt, he is to be called upon kindly; and if he refuſes, then letters of requeſt are to go to his maſter. Neither can any of the ambaſſador's domeſtic ſervants, that are regiſtered in the ſecretaries of ſtate's office, be arreſted in perſon or goods; if they are, the proceſs ſhall be void. and the parties ſuing out and executing it, ſhall ſuffer and be liable to ſuch penalties and corporal puniſhment as the lord chancellor, or either of the chief juſtices, ſhall think fit to inflict. Yet, ambaſſadors cannot be defended when they commit any thing againſt that ſtate, or the perſon of the prince, with whom they reſide; and, if they are guilty of treaſon, felony, &c. or any other crime againſt the law of nations, they loſe the privilege of an ambaſſador, and may be ſubject to puniſhment as private aliens.

AMBE, in ſurgery, the name of an inſtrument for reducing diſlocated bones. In anatomy it implies ſuperficial jutting out of a bone.

AMBER Succinum, or Karabe, in natural hiſtory, a ſolid, hard, ſemipellucid, bituminous ſubſtance, of a particular nature, of uſe in medicine, and in ſeveral of the arts. It has been called *ambra* by the Arabians, and *electrum* by the Greeks.

Amber has been of great repute in the world from the earlieſt times. Many years before Chriſt it was in eſteem as a medicine; and Plato, Ariſtotle, Herodotus, Æſchylus, and others, have commended its virtues. In the times of the Romans it became in high eſteem as a gem; and, in the luxurious reign of Nero, immenſe quantities of it were brought to Rome, and uſed for ornamenting works of various kinds.

The moſt remarkable property of this ſubſtance is, that when rubbed, it draws or attracts other bodies to it; and this, it is obſerved, it does, even to thoſe ſubſtances which the ancients thought it had an antipathy to; as oily bodies, drops of water, human ſweat, &c. Add to this, that, by the friction, it is brought to yield light pretty copiouſly in the dark; whence it is reckoned among the native phoſphori.

Amber aſſumes various figures in the ground, as that of a pear, an almond, a pea, &c.

In amber there have been ſaid to be letters found very well formed; and even Hebrew and Arabic characters. Within ſome pieces, leaves, inſects, &c. have likewiſe been found included; which ſeems to indicate, either that the amber was originally in a fluid ſtate, or that having been expoſed to the ſun, it was once ſoftened, and rendered pliable to leaves, inſects, &c. which came in its way.

It is obſerved by the inhabitants of thoſe places where amber is produced, that all animals, whether terreſtrial, aerial, or aquatic, are extremely fond of it, and that pieces of it are frequently found in their excrements. The bodies of inſects, found buried in amber, are viewed with admiration by all the world; but of the moſt remarkable of theſe, many are to be ſuſpected as counterfeit; the great price at which beautiful ſpecimens of this kind ſell, having tempted ingenious cheats to introduce animal bodies in ſuch artful manners, into ſeemingly whole pieces of amber, that it is not eaſy to detect the fraud.

Of thoſe inſects which have been originally incloſed in amber, ſome are plainly ſeen to have ſtruggled hard for their liberty, and even to have left their limbs behind them in the attempt; it being no unuſual thing to ſee, in a maſs of amber that contains a ſtout beetle, the animal wanting one, or perhaps two of its legs; and thoſe legs left in different places, nearer that part of the maſs from which it has travelled.

This may, in ſome meaſure, account for the common accident of finding legs, or wings of flies, without the reſt of their bodies, in pieces of amber; the inſects having, when entangled in the yet ſoft and viſcid matter, eſcaped, at the expence of leaving thoſe limbs behind them.

Gold and ſilver, as well as iron, are found in various ſhapes immerſed in amber; and the latter is often ſeen eroded, and, ſometimes, in the ſtate of vitriol; it is not impoſſible but that copper, and the other metals, may be alſo ſometimes immerſed in it in the ſame ſtate: hence the bluiſh and greeniſh colours frequently found in pieces of amber.

Naturaliſts have been greatly divided as to the origin of this ſubſtance, and what claſs of bodies it belongs to; ſome referring it to the vegetable, others to the mineral, and ſome even to the animal kingdom. Pliny deſcribes it as "a reſinous juice, oozing from aged pines and firs, (others ſay from poplars, whereof there are whole foreſts on the coaſt of Sweden) and diſcharged thence into the ſea, where, undergoing ſome alteration, it is thrown, in this form, upon the ſhores of Pruſſia, which lie very low. He adds, that it was hence the ancients gave it the denomination *ſuccinum*; from *ſuccus*, juice."

It is certain that all amber is of the ſame origin, and probably that which is found in the ſea has been waſhed thither out of the cliffs. The ſea-amber is uſually finer to the eye than the foſſile; but the reaſon is, that it is diveſted of that coarſe coat with which the other is covered while in the earth.

There are ſeveral indications which diſcover where amber is to be found. The ſurface of the earth is covered with a ſoft ſcaly ſtone; and vitriol in particular always abounds there, which is ſometimes found white, ſometimes reduced into a matter, like melted glaſs, and ſometimes figured like petrified wood.

Amber of the fineſt kind has been found in England. It is frequently thrown on the ſhores of Yorkſhire, and many other places, and found even in our clay-pits: the pits dug for tile-clay, between Tyburn and Kenſington gravel-pits, and that behind St. George's Hoſpital at Hyde-park-corner, have afforded fine ſpecimens.

Poland, Sileſia, and Bohemia, are famous for the amber dug up there at this time. Germany affords great quantities of amber, as well dug up from the bowels of the earth, as toſſed about on the ſhores of the ſea and rivers there. Saxony, Miſnia, and Sweden, and many other places in this track of Europe, abound with it. Denmark has afforded, at different times, ſeveral quantities of foſſile amber; and the ſhores of the Baltic abound with it. But the countries lying on the Baltic afford it in the greateſt abundance of all; and of theſe the moſt plentiful country is Pruſſia, and the next Pomerania. Pruſſia was, as early as the times of Theodoric the Goth, famous for amber. This article alone brings his Pruſſian majeſty a very conſiderable revenue annually. The amber of Pruſſia is not only found on the ſea-coaſts, but in digging; and though that of Pomerania is generally brought from the ſhores, yet people who dig, on different occaſions, in the very heart of the country, at times find amber.

Amber has a ſubacrid reſinous taſte, and fragrant aromatic ſmell, eſpecially when diſſolved. It differs from the other bituminous ſubſtances in this, that it yields by diſtillation a volatile acid ſalt, which none of the others do; otherwiſe it affords the ſame ſort of principles as them, viz. an acid phlegm, an oil that gradually becomes thicker as the diſtillation is continued; and when the operation is finiſhed, there remains a black caput mortuum in the retort. When boiled in water, it neither ſoftens or undergoes any ſenſible alteration. Expoſed to the fire in an open veſſel, it melts into a black maſs very like a bitumen: it is partly ſoluble in ſpirit of wine, and likewiſe in ſome eſſential oils; but it is with difficulty that the expreſſed ones are brought to act upon it; the ſtrongeſt ſorts of fixed alkaline lixivia almoſt totally diſſolve it.

This ſubſtance is principally of two colours, white and yellow. The white is the moſt eſteemed for medicinal purpoſes, as being not only more odoriferous, but containing the greateſt quantity of volatile ſalt; though the yellow is moſt valued by thoſe who manufacture beads and other toys with it, by reaſon of its tranſparency. When once amber has been melted, it irrecoverably loſes its beauty and hardneſs.

Amber in ſubſtance has been much recommended in medicine. The forms in which it is prepared are, a tincture, a ſalt, and an oil, for the preparation and uſes of which ſee Syſtem of PHARMACY.

Amber Tree, the Engliſh name of a ſpecies of ANTHOSPERMUM.

AMBERGREASE, **Ambergris**, or **Grey Amber**, in natural hiſtory, is a ſolid, opake, aſh-coloured, inflammable ſubſtance, variegated like marble, remarkably light, rugged and uneven in its ſurface, and has a fragrant odour when heated. It does not efferveſce with acids; it melts freely over the fire, into a kind of yellow roſin; and is hardly ſoluble in ſpirit of wine.

It is found ſwimming on the ſea, or the ſea-coaſt, or in the ſand near the ſea-coaſt; eſpecially in the Atlantic Ocean, on the ſea-coaſt of Braſil, and that of Madagaſcar; on the coaſt of Africa, of the Eaſt Indies, China, Japan, and the Molucca Iſlands; but moſt of the ambergris which is brought to England comes from the Bahama Iſlands, from Providence, &c. where it is found on the coaſt.

It is alſo ſometimes found in the abdomen of whales, in lumps of various ſhapes and ſizes, weighing from half an ounce to an hundred and more pounds. An American fiſherman from Antigua found, ſome years ago, about 52 leagues ſouth-eaſt from the Windward Iſlands, a piece of ambergris in a whale, which weighed about 130 pounds, and ſold for 500l. ſterling.

There have been many different opinions concerning the origin of this ſubſtance.

It has been ſuppoſed to be a foſſile bitumen or naphtha, exuding out of the bowels of the earth in a fluid form, and diſtilling into the ſea, where it hardens and floats on the ſurface. But having been frequently found in the belly of whales, it has by others been conſidered as entirely an animal production.

That ambergris is found either upon the ſea and ſea-coaſt, or in the bowels of whales, is a matter of fact univerſally credited. But it has never been examined into and determined, whether the ambergris found upon the ſea and ſea-coaſt is the ſame as that found in the whale, or whether they are different from one another? Whether that found on the ſea or ſea-coaſt has ſome properties, or conſtituent parts, which that found in the whale has not? And laſtly, Whether that found in the whale is ſuperior or inferior in its qualities and value to the former?

The uſe of ambergris in Europe is now nearly confined to perfumery, though it has formerly been recommended in medicine by ſeveral eminent phyſicians. Hence the Eſſentia Ambræ Hoffmanni, Tinctura Regia Cod. Pariſini, Trochiſci de Ambra Ph. Wurtemberg, &c.

In Aſia and part of Africa ambergris is not only uſed as a medicine and a perfume, but likewiſe in cookery, by adding it to ſeveral diſhes as a ſpice. A great quantity of it is alſo conſtantly bought by the pilgrims who travel to Mecca; probably to offer it there, and make uſe of it in fumigations, in the ſame manner as frankincenſe is uſed in Catholic countries.

The Turks make uſe of it as an aphrodiſiac. Our perfumers add it to ſcented pillars, candles, balls or bottles, gloves and hair-powder; and its eſſence is mixed with pomatums for the face and hands, either alone or mixed with muſk, &c. though its ſcent to ſome perſons is very offenſive.

Ambergris may be known to be genuine by its fragrant ſcent when a hot needle or pin is thruſt into it, and its melting like fat of an uniform conſiſtence; whereas the counterfeit will not yield ſuch a ſcent, nor prove of ſuch a fat texture.

AMBERING, in perfumery, denotes the ſcenting of any ſubſtance with amber.

AMBETTUWAY, in botany, the name of a tree, the leaves of which, when boiled in wine, are ſaid to create an appetite, and is uſed by the people in Guinea with that intention.

AMBIDEXTER, a perſon who can uſe both hands with the ſame facility, and for the ſame purpoſes, that the generality of people do their right hand only. As to the natural cauſe of this faculty, ſome, as Hœfer, attribute it to an extraordinary ſupply of blood and ſpirits from the heart and brain, which furniſh both hands with the neceſſary ſtrength and agility: others, as Nicholas Maſſa, to an erect ſituation of the heart, inclining neither to the right hand or left; and others to the right and left ſubclavian arteries being of the ſame height and the ſame diſtance from the heart, by which the blood is propelled with equal force to both hands.

Many think, that, were it not for education and habit, all mankind would be ambidexters; and in fact, we frequently find nurſes obliged to be at a good deal of pains before they can bring children to forego the uſe of their left hands. How far it may be an advantage to be deprived of half our natural dexterity, may be doubted. It is certain, there are infinite occaſions in life, where it would be better, could it be acquired, to have an equal uſe of both hands.

Various inſtances occur in hiſtory, where the left hand has been exerciſed in preference to the right. But by the laws of the ancient Scythians, people were enjoined to exerciſe both hands alike; and Plato enjoins ambidexterity to be obſerved and encouraged in his republic.

Ambidexter, as a law phraſe, ſignifies a juror, who accepts money of both parties, on a promiſe of giving his verdict for each; an offence for which he is liable to be impriſoned, for ever excluded from a jury, and to pay ten times the ſum he accepted.

AMBIENT, a term uſed for ſuch bodies, eſpecially fluids, as encompaſs others on all ſides: thus, the air is frequently called an ambient fluid, becauſe it is diffuſed round the earth.

AMBIGENÆ Oves, in the heathen ſacrifices, an appellation given to ſuch ewes as, having brought forth twins, were ſacrificed with their two lambs, one on each ſide. We find them mentioned among other ſacrifices to Juno.

AMBIGENAL Hyperbola, a name given by Sir Iſaac Newton to one of the triple hyperbolas of the ſecond order, having one of its infinite legs falling within an angle formed by the aſſymptotes, and the other without.

AMBIGU denotes an irregular or promiſcuous manner of laying out a table, that indicates no regular meal.

AMBIGUITY, a defect of language, whereby words are rendered ambiguous.

AMBIGUOUS, a term applied to a word or expreſſion which may be taken in different ſenſes. The reſponſes of the ancient oracles were always ambiguous.

AMBIT, in geometry, is the ſame with what is otherwiſe called the perimeter of a figure.

Ambit was particularly uſed, in antiquity, to denote a ſpace of ground to be left vacant betwixt one building and another. By the laws of the twelve tables, houſes were not to be built contiguous, but an ambit or ſpace of 2½ feet was to be left between each, for fear of fire.

The ambitus of a tomb or monument denoted a certain number of feet, in length and breadth, around the ſame, within which the ſanctity aſſigned to it was limited. The whole ground wherein a tomb was erected, was not to be ſecreted from the common uſes; for this reaſon, it was frequent to inſcribe the ambit on it, that it might be known how far its ſanctity extended.

AMBITION, *ambitio*, is generally uſed for an immoderate or illegal purſuit of power.

In the ſtrict meaning, however, of the word, it ſignifies the ſame with the *ambitus* of the Romans.

Ambition, in the former, and more uſual ſenſe, is one of thoſe paſſions that is never to be ſatiſfied. It ſwells gradually with ſucceſs, and every acquiſition ſerves but as a ſpur to further attempts.

"If a man, (ſays a celebrated writer) could at once accompliſh all his deſires, he would be a miſerable creature; for the chief pleaſure of this life is to wiſh and deſire. Upon this account, every prince, who aſpires to be deſpotic, aſpires to die of wearineſs. Searching every kingdom for the man who has the leaſt comfort in life, Where is he to be found? In the royal palace. What! his majeſty? Yes; eſpecially if he be deſpotic."

AMBITUS, in Roman antiquity, the ſetting up for ſome magiſtracy or office, and formally going round the city to ſolicit the intereſt and votes of the people.

Ambitus differed from ambition, as the former lies in the act, the latter in the mind.

Ambitus was of two kinds; one lawful, the other infamous. The firſt, called alſo *ambitus popularis*, was when a perſon offered his ſervice to the republic frankly, leaving it to every body to judge of his pretenſions as they found reaſonable.

The means and inſtruments here made uſe of were various. 1. *Amici*, or friends, under different relations, including *cognati, affines, neceſſarii, familiares, vicini, tribules, clientes, municipes, ſodales, collegæ*. 2. *Nomenclatura*, or the calling and ſaluting every perſon by his name; to which purpoſe, the candidates were attended with an officer, under the denomination of *interpres*, or *nomenclator*. 3. *Blanditia*; or obliging perſons, by ſerving them, or their friends, patrons, or the like, with their vote and intereſt on other occaſions. 4. *Prenſatio*; the ſhaking every perſon by the hand, offering him his ſervice, friendſhip, &c. The ſecond kind was that wherein force, cajoling, money, or other extraordinary influence, was made uſe of. This was held infamous, and ſeverely puniſhed, as a ſource of corruption and other miſchiefs.

Ambitus, in muſic, denotes the modification of each tone, whether ſharp, flat, or natural; or, in other words, is the extent from flat to ſharp.

In the plain chant this word is again uſed; but the ambitus of perfect modes is only of one octave therein; thoſe that exceed it, are called ſuperfluous modes; and thoſe that do not reach it, are called diminiſhed, or leſſened modes.

AMBIX is a ſynonymous term for alembic.

AMBLE, or **Ambling**, in horſemanſhip, a peculiar pace by which a horſe's two legs of the ſame ſide move at the ſame time.

AMBLYGON, in geometry, denotes an obtuſe-angled triangle, or a triangle, one of whoſe angles conſiſts of more than 90 degrees.

AMBLYOPY, among phyſicians, ſignifies an obſcuration of the ſight, ſo that objects at a diſtance cannot be clearly diſtinguiſhed.

AMBO, or Ambon, a kind of pulpit or deſk, in the ancient churches, where the prieſts and deacons ſtood to read or ſing part of the ſervice, and preach to the people; called alſo *analogium.* The ambo was aſcended by ſteps; which occaſioned that part of the office performed there to be called the *gradual.*

Beſides the goſpel, which was read at the top of the ambo, and the epiſtle, which was read a ſtep lower, they likewiſe publiſhed from this place the acts of the martyrs, the commemoration of departed ſaints, and the letters of peace and communion ſent by one church to another: here, too, converts made a public profeſſion of their faith; and biſhops, their defence, when accuſed: treaties alſo were ſometimes concluded, and the coronations of emperors and kings performed, in the ſame place.

The modern reading-deſks and pulpits have been generally ſubſtituted to the ancient ambos; though, in ſome churches, remains of the ambos are ſtill ſeen.

AMBONUM, in natural hiſtory, denotes the prominent tubercles on many ſtones expoſed to the open air.

AMBREADA, thus they call the falſe amber, which the Europeans uſe in their trade with the negroes on the coaſt of Africa, and particularly on the river Senegal.

AMBRONES, a Gauliſh people, who lived near the foot of the Alps, between Switzerland and Provence. They invaded the Roman territories in conjunction with the Cimbri and Tentones; but were defeated with great ſlaughter by Marius, about 101 years before Chriſt.

AMBROSE, or St. Ambroſe in the Wood, an order of religious, who uſe the Ambroſian office, and wear an image of that ſaint engraven on a little plate: in other reſpects they conform to the rule of the Auguſtins.

AMBROSIA, in heathen antiquity, denotes the ſolid food of the gods, in contradiſtinction from the drink, which was called nectar. It had the appellation ambroſia, (compounded of the particle *α*, and βροτος, immortal) as being ſuppoſed to render thoſe immortal who fed on it.

Ovid tells us the horſes of the ſun feed upon ambroſia inſtead of graſs.

> *Ambroſiam per gramine habent.*
> Met. lib. ii. v. 214.

And, deſcribing the deification of Æneas, he ſays;

> *Luſtratum genitrix divino corpus odore*
> *Unxit, et ambroſia cum dulci nectare miſta*
> *Contigit os, fecitque decum.*
> Id. lib. xiv. v. 605.

> His better part by luſtral waves refin'd,
> Wore pure, and nearer to the ætherial mind,
> With gums of fragrant ſcent the goddeſs ſtrews,
> And on his features breathes ambroſial dews:
> Thus deified——

Ambrosia is alſo a ſplendid kind of title, given by ſome phyſicians to certain alexipharmic compoſitions, of extraordinary virtue. The name was particularly given to a famous antidote of Philip of Macedon, againſt all poiſons, bites, and ſtings of venomous creatures, as well as many internal diſeaſes.

Ambrosia, a genus of the pentandria order, belonging to the monœcia claſs of plants; and, in the natural method, ranking under the 49th order, *compoſitæ-nucamentaceæ.* Of this genus five ſpecies are enumerated; but neither have any properties worthy of notice. For the characters ſee Syſtem of Botany.

AMBROSIAN Office, or Rite, in church hiſtory, a particular formula of worſhip in the church of Milan, which takes its name from St. Ambroſe, who inſtituted that office in the fourth century. Each church originally had its particular office; and when the pope, in after-times, took upon him to impoſe the Roman office upon all the weſtern churches, that of Milan ſheltered itſelf under the name and authority of St. Ambroſe; from which the ambroſial ritual has prevailed.

AMBROSIN, in middle-age writers, denotes a coin ſtruck by the lords or dukes of Milan, whereon was repreſented St. Ambroſe on horſeback, with a whip in his right hand. The occaſion of this coinage is ſaid to have been a viſion of that ſaint, who appeared to the Milaneſe general in 1339, during the time of battle; but this viſion muſt be conſidered as fabulous.

AMBROSINIA, in botany, a genus of the polyandria order belonging to the gynandria claſs of plants.

AMBRY, a place in which were formerly depoſited all utenſils neceſſary for houſe-keeping. In the ancient abbeys and priories, there was an office under this denomination, in which all charities were laid up and diſtributed to the poor.

AMBUBAJÆ, in Roman antiquity, were immodeſt women, who came from Syria to Rome, where they lived by proſtitution, and by playing on the flute: the word is derived from the Syriac *abub,* which ſignifies a flute; although others make it to come from *am* and *Baiæ,* becauſe theſe proſtitutes often retired to *Baiæ.* According to Cruquius, theſe women uſed likewiſe to ſell paint for ornamenting the face, &c.

AMBUBEIA, in botany, a trivial name of the wild ſuccory.

AMBULANT, or Ambulatory. They give in France the name of *ambulant commiſſioners* to thoſe commiſſioners, or clerks of the king's farms, who have no ſettled office; but viſit all the offices within a certain diſtrict, to ſee that nothing be done in them againſt the king's right and the intereſt of the farm.

Ambulant is alſo uſed to denote thoſe brokers at Amſterdam, or exchange agents, who have not been ſworn before the magiſtrates. They tranſact brokerage buſineſs, but their teſtimony is not received in the courts of juſtice.

AMBULATION, a ſynonymous term for exerciſe, by walking on foot a conſiderable time.

Ambulation, among ſurgeons, ſignifies the firſt ſymptom of a mortification.

AMBULATORY, a term anciently applied to ſuch courts, &c. as were not fixed to any certain place; but held ſometimes in one place, and ſometimes in another. In oppoſition to ſtationary courts. The court of parliament was anciently ambulatory; ſo alſo were the courts of king's bench, &c.

AMBURBIUM, in Roman antiquity, a proceſſion, made by the Romans round the city and pomœrium, in which they led a victim, and afterwards ſacrificed it, in order to avert ſome calamity that threatened them.

AMBURY, or Anbury, a term among farriers, ſignifying a tumor, wart, or ſwelling, which is ſoft to the touch, and full of blood.

This diſorder of horſes is cured by tying a horſe-hair very hard about its root; and, when it has fallen off, which commonly happens in about eight days, ſtrewing ſome powder of verdigris upon the part, to prevent the return of the complaint. If the tumor be ſo low that nothing can be tied about it, they cut it out with a knife, or elſe burn it off with a ſharp hot iron; and, in ſinew parts, where a hot iron is improper, they eat it away with oil of vitriol, or white ſublimate.

Many farriers boaſt of a ſecret which infallibly cures all kinds of protuberances of this kind; the receipt for which is this:

Take three ounces of green vitriol and one ounce of white arſenic; beat them to a coarſe powder, and put them into a crucible; place the crucible in the midſt of a charcoal fire, ſtirring the ſubſtance, but carefully avoiding the poiſonous ſteams; when the whole grows reddiſh, take the crucible out of the fire; and, when cool, break it and take out the matter at the bottom; beat this to powder in a mortar, and add to four ounces of this powder five ounces of album rhoſis; make the whole into an ointment, and let it be applied cold to warts; rubbing them with it every day. They will by this means fall off gently and eaſily, without leaving any ſwellings. It is beſt to keep the horſe quiet, and without working, during the cure. What ſores remain on the parts which the ſwellings fall off from, may be cured with the common application called the *counteſs's ointment.*

AMBUSCADE, or Ambush, in military affairs, properly denotes a place where ſoldiers may lie concealed till they find an opportunity to ſurpriſe the enemy.

AMEA, in botany, a medicinal plant not enumerated by Linnæus. It is found in ſeveral parts of Africa, particularly the coaſt of Guinea, where the negroes uſe it with ſucceſs to ſtop bleeding at the noſe.

AMEDIANS, or Amedei, in church hiſtory, a congregation of religious in Italy, ſo called from their profeſſing themſelves *amantes Deum,* lovers of God; or rather *amati Deo,* beloved of God. They wore a grey habit and wooden ſhoes, had no breeches, and girt themſelves with a cord. They had 28 convents; and were united by Pope Pius V. partly with the Ciſtercian order, and and partly with that of the Soccolanti, or wooden-ſhoe wearers.

AMELLUS, Starwart, a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ-oppoſitifoliæ.* Of this there are two ſpecies. 1. The lynchitis, with one flower on each footſtalk. This is a native of the Cape of Good Hope. It is a perennial plant, riſing about three feet high, ſpear-ſhaped leaves placed oppoſite, by ſingle naked flower-ſtalks, each ſupporting one violet-coloured flower, having a yellow diſk, which is ſucceeded by oblong ſeeds. 2. The umbellatus, with flowers growing in umbels, is a native of Jamaica. The firſt is eaſily propagated, either by cuttings planted in the ſummer-months, or by ſeeds ſown on a moderate hot-bed in the ſpring, but the plants require a ſlight ſhelter in winter. The ſecond is much more tender, and therefore requires to be preſerved in a ſtove during the winter ſeaſon.

AMEN, ſignifies *true, faithful, certain.* It is made uſe of likewiſe to affirm any thing, and was a ſort of affirmation uſed often by our Saviour: Αμην, Αμην, λεγω υμιν, i. e. *Verily, Verily, I ſay unto you.* Laſtly, it is underſtood as expreſſing a wiſh; as

Amen, So be it, Numb. v. 22. or an affirmation, *Amen, yes I believe it,* 1 Cor. xiv. 16. The Hebrews and the five books of Pſalms, according to their way of diſtributing them, with the words *amen, amen*; which the Septuagint have tranſlated, *γενοιτο, γενοιτο*; and the Latins *fiat, fiat.*

The Greek and Latin churches have preſerved this word in their prayers, as well as *alleluiah* and *hoſanna*; becauſe they obſerved more energy in them than in any terms which they could uſe in their own languages. At the concluſion of the public prayers, the people anſwered with a loud voice, Amen; and St. Jerom ſays, that at Rome when the people anſwered Amen, the ſound of their voices was like a clap of thunder: *In ſimilitudinem cæleſtis tonitrui Amen reboat.* The Jews aſſert that the gates of heaven are open to him who anſwers *Amen* with all his might.

AMENABLE, in law, implies a right to bring a perſon that has offended, to abide by the juriſdiction of the court; or in other words, to be dealt with according to law.

In many caſes, a married woman is freed from the puniſhment due to felonious tranſactions, wherein her huſband was a principal, merely becauſe ſhe is ſuppoſed to be amenable, or under the government of her huſband.

AMEND, or AMENDE, in the French cuſtoms, a pecuniary puniſhment impoſed by a judge for any crime, falſe proſecution, or groundleſs appeal.

AMENDE *Honourable,* an infamous kind of puniſhment inflicted in France upon traitors, parricides, or ſacrilegious perſons, in the following manner: the offender being delivered into the hands of the hangman, his ſhirt is ſtripped off, a rope put about his neck, and a taper in his hand; then he is led into court, where he muſt beg pardon of God, the king, the court, and his country. Sometimes the puniſhment ends here; but at others it is only a prelude to death, or baniſhment to the galleys.

AMENDE *Honourable,* is a term alſo uſed for making recantation in open court, or in preſence of the perſon injured.

AMENDMENT, in a general ſenſe, denotes ſome alteration or change made either in a perſon, or thing, for the better.

AMENDMENT, in law, the correction of an error committed in a proceſs, which may be amended after judgment, unleſs the error lies in giving judgment; which in caſe it is not amendable, yet the party is at liberty to bring a writ of error. A bill may be amended on the file at any time before the plea is pleaded; but not afterwards, without a motion for leave of the court.

AMENDMENT *of a Bill,* in parliament, is ſome alteration made in the firſt draught of it.

AMENTUM, in botany, the name of a ſpecies of calyx, conſiſting of valves, and hanging down in different directions from the caulis. Common oats afford a good example of the amentum. This word imports the ſame as Amentaceous.

AMENTUM, in Roman antiquity, a thong tied about the middle of a javelin or dart, and faſtened to the fore-finger, in order to recover the weapon as ſoon as it was diſcharged. The ancients made great uſe of the amentum, thinking it helped to enforce the blow. It alſo denotes a latchet for their ſandals.

AMERADE, a kind of officers among the Saracens, anſwering to the governors of provinces among the Europeans. The name is originally the ſame with that of emir.

AMERCEMENT, or AMERCIAMENT, in law, a pecuniary puniſhment impoſed on offenders at the diſcretion of the court.

AMERICAN NIGHT-SHADE, a ſynonyme of Phytolacca.

AMERICAN GROUND-NUT, a ſynonyme of Arrachis.

AMETHYST, in natural hiſtory, a tranſparent gem of a purple colour, which ſeems compoſed of a ſtrong blue and a deep red; and, according as either of thoſe prevails, affording different tinges of purple, ſometimes approaching to violet, and ſometimes even fading to a pale-roſe colour.

Though the amethyſt is generally of a purple colour, it is nevertheleſs ſometimes found naturally colourleſs, and may at any time be eaſily made ſo by putting it into the fire; in which pelucid or colourleſs ſtate, it ſo reſembles the diamond that the want of hardneſs ſeems the only way of diſtinguiſhing it.

Some derive the name amethyſt from its colour, which reſembles wine mixed with water; whilſt others, with more probability, think it got its name from its ſuppoſed virtue of preventing drunkenneſs; an opinion which, however imaginary, prevailed to that degree among the ancients, that it was uſual for great drinkers to wear it about their necks. The amethyſt is ſcarce inferior to any gem in the beauty of its colour; and in its pureſt ſtate is of the ſame hardneſs, and at leaſt of equal value, with the ruby and ſapphire.

It is found of various ſizes, from the bigneſs of a ſmall vetch, to an inch and an half in diameter, and often to much more than that in length. Its ſhape is extremely various, ſometimes roundiſh, ſometimes oblong, and at others flatted, at leaſt on one ſide; but its moſt common appearance is in a cryſtalliform figure, conſiſting of a thick column, compoſed of four plants, and terminated by a flat and ſhort pyramid, of the ſame number of ſides; or elſe, of a thinner and longer hexangular column; and ſometimes of a long pyramid, without any column. It makes the gayeſt figure in the laſt of theſe ſtates, but is hardeſt and moſt valuable in the roundiſh and pebble-like form.

The amethyſt is found in the Eaſt and Weſt Indies, and in ſeveral parts of Europe; the oriental ones, at leaſt ſome of the finer ſpecimens, being ſo hard and bright as to equal any of the coloured gems in value. However, by far the greater number of amethyſts fall infinitely ſhort of theſe; as all the European ones, and not a few of thoſe brought from the Eaſt and Weſt Indies, are very little harder than common cryſtal.

Counterfeit or Fictitious AMETHYST. Spars and cryſtals tinged red and yellow, &c. are ſold for amethiſts. The falſe ones come from Germany, are tinged by vapours in the mines, and contain ſome lead.

AMETHYST, in heraldry, a term for the purple colour in the coat of a nobleman, in uſe with thoſe who blazon with precious ſtones, inſtead of metals and colours. This, in a gentleman's eſcutcheon, is called *Purpure*; and in thoſe of ſovereign princes, *Mercury.*

AMETHYSTEA, or AMETHYST, in botany, a genus of the monogynia order, belonging to the diandria claſs of plants; and, in the natural method, ranking under the 42d order, *Verticillatæ.* There is only one known ſpecies.

This plant is a native of Siberia. It is an annual plant, with an upright ſtalk, which riſes about a foot high. Towards the top it puts forth two or three lateral branches, garniſhed with ſmall trifid leaves, ſawed on their edges, of a very dark green colour. It flowers in June or July, and produces in ſmall umbels at the extremities of the branches. The colour is a fine blue, and the leaves immediately under the umbel, make a fine appearance. The ſeeds ſhould be ſown in autumn, where they are to remain, as they do not thrive when tranſplanted.

AMETHYSTINE, is applied, in antiquity, to a kind of purple garment dyed of the hue of amethyſt. In this ſenſe amethyſtine differed from *Tyrian* as well as from *hyacinthine* purple, being a kind of medium between both.

AMGAILAM, or AMGAILA, in medicine, implies a ſynonyme of the Acanthian root, uſed in cardiac and ſtomachic compoſitions.

AMIA, in ichthyology, the name of a very large ſea fiſh, the ſame as the glaucus or leccia; it is of the ſalmon ſpecies and common to the Mediterranean. It is the ſcomber of Linnæus. The thunny is ſometimes called by this name.

AMIANTHUS, or EARTH-FLAX, in natural hiſtory, a fibrous, flexile, elaſtic, mineral ſubſtance, conſiſting of ſhort, abrupt, and interwoven filaments. It is found in Germany, in the ſtrata of iron ore, ſometimes forming veins of an inch in diameter. Its fibres are ſo flexible that cloth has been made of them, and the ſhorter filaments that ſeparate in the waſhing of the ſtone may be made into paper in the common manner.

Amianthus is claſſed by Mr. Kirwan in the muriatic genus of earths, becauſe it contains about a fifth part of magneſia. Its other conſtituents are, flint, mild calcareous earth, barytes, clay, and a very ſmall proportion of iron. It is fuſible *per ſe* in a ſtrong heat, and alſo with the common fluxes. It differs from aſbeſtos in containing ſome ponderous earth.

AMICABLE, in a general ſenſe, denotes any thing done in a friendly manner, or to promote peace.

AMICABLE *Benches,* in Roman antiquity, were, according to Pitiſcus, lower and leſs honourable ſeats allotted for the *judices pedanei,* or inferior judges, who, upon being admitted of the emperor's council, were dignified by him with the title *amici.*

AMICABLE *Numbers,* ſuch as are mutually equal to the ſum of one another's aliquot parts. Thus the numbers 284 and 220 are amicable numbers: for the aliquot parts 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, of 220, are together equal to the other numbers 284; and the aliquot parts 1, 2, 4, 71, 142, of 284, are together equal to 220.

AMICITIA, in law, denotes a holding of lands rent-free during the pleaſure of the donor.

AMICTUS, in Roman antiquity, was any upper garment worn over the tunica.

AMICTUS, among eccleſiaſtical writers, the uppermoſt garment anciently worn by the clergy; the other five being the alba, ſingulum, ſtola, manipulus, and planeta. The amictus was a linen garment, of a ſquare figure, covering the head, neck, and ſhoulders, and buckled or claſped before the breaſt. It is ſtill worn by the religious abroad.

AMICULUM, in Roman antiquity, a woman's upper garment, which differed from the palla. It was worn both by matrons and courtezans.

AMICUS CURIÆ, a law term, to denote a byſtander who informs the court of a matter in law that is doubtful or miſtaken.

AMIDA, or AMIDAS, an idol of the Japaneſe, who has many temples erected to it in the iſland of Japan, of which the principal is at Jedo. The Japaneſe have ſuch a confidence in it, that they hope to attain eternal felicity by the frequent invocation of its name. One of the figures of this idol is repreſented at Rome.

AMIDSHIPS, a nautical expreſſion, implies the middle of a ſhip, either with regard to length or breadth. Thus, "the enemy boarded us amidſhips," that is to ſay, midway between ſtem and ſtern. Or, "Put the helm amidſhips," i. e. in the middle between the two ſides.

AMIESTES, in commerce, ſignifies the cottons (wrought) imported from the Eaſt Indies.

AMILICTI, in the Chaldaic theology, denote a kind of intellectual powers, or perſons in the divine hierarchy. The amilicti are repreſented as three in number; and conſtitute one of the tryads, in the third order of the hierarchy.

AMINEUM Acetum, in medical preſcriptions, denotes white wine vinegar.

AMIRANTE, in the Spaniſh polity, a great officer of ſtate, anſwering to our lord high-admiral.

AMITTERE Legem Terræ, among lawyers, a phraſe importing the loſs of liberty of ſwearing in any court: the puniſhment of a champion overcome or yielding in battle, of jurors found guilty in a writ of attaint, and of a perſon outlawed.

AM-KAS, in hiſtory, a name given to a ſpacious ſaloon in the palace of the Great Mogul, where he gives audience to his ſubjects, and where he appears on ſolemn feſtivals with extraordinary magnificence. His throne is ſupported by ſix large ſteps of maſſy gold, ſet with rubies, emeralds, and diamonds, eſtimated at 60,000,000 l.

AMMA, or Hamma, among eccleſiaſtical writers, a term uſed to denote an abbeſs or ſpiritual mother.

AMMAN, or Ammant, in the German and Belgic policy, a judge who has the cognizance of civil cauſes. It is alſo uſed among the French for a public notary, or officer, who draws up inſtruments and deeds.

AMMANIA, in botany, a genus of the monogynia order, belonging to the tetrandria claſs of plants; and in the natural method ranking under the 17th order, Calycanthemæ. For the characters ſee Syſtem of Botany. Of this genus there are three ſpecies, all natives of warm climate; but they have neither beauty or any remarkable property.

AMMI, Biſhop's-weed: a genus of the digynia order, belonging to the pentandria claſs of plants; and ranking, in the natural method, under the 45th order, *Umbellatæ*.

There are three ſpecies. 1. The majus, or common biſhop's-weed, the ſeeds of which are uſed in medicine. 2. The glaucifolium, or ſpear biſhop's-weed. 3. The copticum, or Egyptian biſhop's-weed.

The firſt is an annual plant; and propagated by ſeeds ſown in autumn, where the plants are to remain. They flower in June, and ripen in Auguſt. The ſecond ſort is perennial, and very hardy.

The ſeeds of the ammi copticum are ſmall, ſtriated, of a reddiſh brown colour, and have a warm pungent taſte, and a pleaſant ſmell approaching to that of origanum. They are recommended as ſtomachic, carminative, and diuretic; but have long been ſtrangers to the ſhops. The ſeeds of the ammi majus, which are uſed in their place, are much weaker both in taſte and ſmell, and without the origanum flavour of the other.

AMMINEA Uva, in botany, a trivial name for the wild or hedge vine found in Italy.

AMMITES, or Ammonites, in mineralogy, ſignifies a rough free ſtone found in Germany, compoſed of ſeveral globular ſhaped petrefactions of ſand.

AMMOCHRYSOS, from *αμμος*, *ſand*, and *χρυσος*, *gold*, a name given to a ſtone very common in Germany, and ſeeming to be compoſed of a golden ſand. It is of a gold colour, and its particles are very gloſſy. It is generally ſo ſoft that it may be rubbed to a powder in the hand. It is uſed only as ſand to ſtrew over writing.

There is another kind of it leſs common, but much more beautiful, conſiſting of the ſame ſort of gloſſy ſpangles, but of a bright red, like vermillion.

AMMODYTES, or Sand-eel, in ichthyology, a genus of fiſhes belonging to the order of apodes. This fiſh reſembles an eel, and ſeldom exceeds a foot in length. The head of the ammodytes is compreſſed, and narrower than the body; the upper jaw is larger than the under; the body is cylindrical, with ſcales hardly perceptible. There is but one ſpecies, the tobianus, or launce, a native of Europe. This fiſh gathers itſelf into a circle, and pierces the ſand with its head in the centre.

Ammodytes, in zoology, a ſerpent, of a ſand colour, of the viper kind.

AMMON, or Hammon, in heathen mythology, the name of the Egyptian Jupiter, worſhipped under the figure of a ram.

Bacchus having ſubdued Aſia, and paſſing with his army through the deſarts of Africa, was in great want of water: but Jupiter, his father, aſſuming the ſhape of a ram, led him to a fountain, where he refreſhed himſelf and his army; in gratitude for which favour, Bacchus built there a temple to Jupiter, under the title of *Ammon*, from the Greek *αμμος*, which ſignifies *ſand*, alluding to the ſandy deſart where it was built. In this temple was an oracle of great note, which Alexander the Great conſulted, and which laſted till the time of Theodoſius.

Hammon, the god of the Egyptians, was the ſame with the Jupiter of the Greeks; for which reaſon theſe latter denominate the city which the Egyptians call No-Hammon, or the habitation of Ammon, Dioſpolis, or the city of Jupiter. He is thought to be the ſame with Ham, who peopled Africa, and was the father of Mizraim, the founder of the Egyptians.

The temple of Jupiter Ammon was famous for its oracle. Lucan brings his hero, the great Cato, to conſult the oracle of Jupiter Ammon, whoſe temple he thus deſcribes:

Ventum erat ad templum, Lybicis quod gentibus unum
Inculti garamantes habent: ſtat corniger illic
Jupiter, ut memorant, ſed non aut fulmina vibrans,
Aut ſimilis noſtro, ſed tatis, cornibus Ammon.

— — — — — — —

Pauper ad huc deus eſt, nullis violata per ævum
Divinitiis delubra tenens; morumque priorum
Numen Romano templum defendit ab auro.

Luc. lib. 9. v. 514.

Now to the ſacred temple they draw near,
Whoſe only altars Lybian lands revere:
There, but unlike the Jove by Rome ador'd,
A form uncouth ſtands Heaven's Almighty Lord.
No regal enſigns grace his potent hand,
Nor ſhakes he there the lightning's flaming brand;
But, ruder to behold, a horned ram,
Belies the God, and Ammon is his name.

— — — — — — —

There plain and poor, and unprofan'd, he ſtood,
Such as, to whom, our great forefathers bow'd:
A god of pious times, and days of old,
That keeps his temple free from Roman gold.

AMMONIAC, a concrete gummy reſinous juice, brought from the Eaſt Indies, uſually in large maſſes, compoſed of little lumps or tears, of a milky colour, but ſoon changing, upon being expoſed to the air, of a yellowiſh hue.

There is no certain account of the plant which affords this juice; the ſeeds uſually found among the tears reſemble thoſe of the umbelliferous claſs.

It has been alleged, that it is an exudation from a ſpecies of the Ferula, another ſpecies of which produces the aſſafœtida.

Ammoniac has a nauſeous ſweet taſte, followed by a bitter one; and a peculiar ſcent ſomewhat like galbanum: it ſoftens in the mouth, and grows of a whiter colour when chewed. It will burn away in flame: and is in ſome meaſure ſoluble in water or vinegar, with the latter of which it aſſumes the appearance of milk; but the reſinous part, amounting to about one half, ſubſides on ſtanding.

Ammoniac is an uſeful deobſtruent, and frequently preſcribed for opening obſtructions of the abdominal viſcera, and in hyſterical diſorders occaſioned by a deficiency of the menſtrual evacuations. It is likewiſe ſuppoſed to deterge the pulmonary veſſels; and proves of conſiderable ſervice in ſome kinds of aſthmas, where the lungs are oppreſſed by viſcid phlegm: in this inſtance, a ſolution of gum ammoniac in vinegar of ſquills proves a medicine of great efficacy, though very unpleaſant. In obſtinate cholics proceeding from viſcid matter lodged in the inteſtines, this gummy reſin has produced happy effects, after the purges and the common carminatives had been uſed in vain. Ammoniac is moſt commodiouſly taken in the form of pills; about a ſcruple may be given every night, or oftener. Externally, it ſoftens and ripens hard tumours: a ſolution of it in vinegar ſtands recommended by ſome for reſolving even ſchirrhous ſwellings. A plaſter made of it and ſquill-vinegar is recommended in white ſwellings. A dilute mixture of the ſame is likewiſe rubbed on the parts, which are alſo fumigated with the ſmoak of juniper-berries. It is prepared with a ſolution of it in pennyroyal water, and called from its milky colour, *lac ammoniaci*.

Sal Ammoniac, a volatile ſalt, of which there are two kinds, ancient and modern. The ancient ſort, deſcribed by Pliny and Dioſcorides, was a native ſalt, generated in thoſe large inns or caravanſeras where the crowd of pilgrims, coming from the temple of Jupiter Ammon, uſed to lodge; who, in thoſe parts, travelling upon camels, and thoſe creatures when in Cyrene, a province of Egypt, where that celebrated temple ſtood, urining in the ſtables, or (ſay ſome) in the parched ſands, out of this urine, which is remarkably ſtrong, aroſe a kind of ſalt, denominated Ammoniac.

Since the ceſſation of theſe pilgrimages, no more of this ſalt has been produced there.

The characters of the ancient ſal ammoniac are, that it cools water, turns aqua fortis into aqua regia, and conſequently diſſolves gold.

The modern ſal ammoniac is entirely factitious.

AMMONITÆ, or Ammonis-cornu, in natural hiſtory, is the ſame as Cornu Ammonis.

AMMONITES, a people dſcended from Ammon the ſon of Lot. The Ammonites deſtroyed thoſe giants which they called Zamzummins (Deut. ii. 19—21.), and ſeized upon their country. God forbad Moſes, and, by him the children of Iſrael, to attack the Ammonites; becauſe he did not intend to give their lands unto the Hebrews. Before the Iſraelites entered the land of Canaan, the Amorites had by conqueſt got great part of the countries belonging to the Ammonites and Moabites. This Moſes retook from the Amorites, and divided between the tribes of Gad and Reuben.

In the time of Jephtha, the Ammonites declared war againſt the Iſraelites (Judges xi.), under pretence that they detained a great part of the country which had formerly been theirs before the Amorites poſſeſſed it.

Jephtha declared, that as this was an acquiſition which the Iſraelites had made in a juſt war, and what they had taken from the Amorites, who had long enjoyed it by right of conqueſt, he was under no obligation to reſtore it. The Ammonites were not ſatisfied with this reaſon; wherefore Jephtha gave them battle and defeated them.

The Ammonites and Moabites generally united whenever there was any deſign ſet on foot of attacking the Iſraelites.

After the death of Othniel, the Ammonites and Amalekites joined with Eglon king of Moab to oppreſs the Hebrews; whom they ſubdued, and governed for the ſpace of 18 years, till they were delivered by Ehud the ſon of Gera, who ſlew Eglon king of Moab. Some time after this, the Ammonites made war againſt the Iſraelites, and greatly diſtreſſed them. But theſe were at laſt delivered by the hands of Jephtha; who having attacked the Ammonites, made a very great ſlaughter among them. In the beginning of Saul's reign, (1 Sam. xi.) Naaſh king of the Ammonites having ſat down before Jabeſh-gilead, reduced the inhabitants to the extremity of demanding a capitulation. Naaſh anſwered, that he would capitulate with them upon no other conditions than their ſubmitting to have every one his right eye plucked out, that ſo they might be made a reproach to Iſrael: but Saul coming ſeaſonably to the relief of Jabeſh, delivered the city and people from the barbarity of the king of the Ammonites.

David had been the king of Ammon's friend; and after the death of this prince, he ſent embaſſadors to make his compliments of condolence to Hanun his ſon and ſucceſſor; who, imagining that David's ambaſſadors were come as ſpies to obſerve his ſtrength, and the condition of his kingdom, treated them in a very injurious manner (2 Sam. x. 4.) David revenged this indignity thrown upon his ambaſſadors, by ſubduing the Ammonites, the Moabites, and the Syrians their allies.

Ammon and Moab continued under the obedience of the kings David and Solomon; and, after the ſeparation of the ten tribes, were ſubject to the kings of Iſrael till the death of Ahab in the year of the world 3107. Two years after the death of Ahab, Jehoram his ſon, and ſucceſſor of Ahaziah, defeated the Moabites (2 Kings iii.) but it does not appear that this victory was ſo complete as to reduce them to his obedience. At the ſame time, the Ammonites, and other people, made an irruption upon the lands belonging to Judah; but were forced back and routed by Jehoſhaphat (2 Chr. xx. 1, 2.). After the tribes of Reuben, Gad, and the half-tribe of Manaſſeh, were carried into captivity by Tiglath-pileſer in the year 3264, the Ammonites and Moabites took poſſeſſion of the cities belonging to theſe tribes. Jeremiah (xlix. 1.) reproaches them for it. The ambaſſadors of the Ammonites were ſome of thoſe to whom this prophet preſented the cup of the Lord's fury, and directed to make bonds and yokes for themſelves; exhorting them to ſubmit themſelves to Nebuchadnezzar, and threatening them, if they did not, with captivity and ſlavery. Ezekiel (xxv. 4. 10) denounces their entire deſtruction; and tells them God would give them up to the people of the eaſt, who ſhould ſet their palaces in their country, ſo that there ſhould be no more mention of the Ammonites among the nations. It is believed that theſe misfortunes happened to the Ammonites in the fifth year after the taking of Jeruſalem, when Nebuchadnezzar made war againſt all the people that dwelt upon the confines of Judea, in the year of the world 3420.

AMMUNITION, a general name for all warlike proviſions; but more particularly powder and ball.

Ammunition and arms, untenſils of war, gun-powder, &c. if imported without licence from his Majeſty, are, by the laws of England, forfeited, in triple the value. And again, ſuch licence obtained, except for furniſhing his Majeſty's public ſtores, is to be void, and the offender to incur a premunire, and to be diſabled to hold any office from the crown.

AMMUNITION *Bread, Shoes, &c.* ſuch as are ſerved out to the ſoldiers of an army or garriſon.

AMNESTY, in matters of policy, denotes a pardon granted by a prince to his rebellious ſubjects, uſually with ſome exceptions: ſuch was that granted by Charles II. at his reſtoration. The word is formed from the Greek *αμνεστια*, the name of an edict of this kind, publiſhed by Thraſibulus, on his expelling the tyrants out of Athens.

AMNIOS, in anatomy, a thin pellucid membrane, which ſurrounds the fœtus in the womb.

AMNÆ, AMNA, or AMNIS, in medical diſtinctions, imports, a kind of ſpring water, which is ſo much impregnated with limy acid, or tinged with white, as to reſemble milk and water. From this kind of mineral ſpring, greater virtues are derived.

AMNIMODAR, in aſtrology, implies the planet, which ruled the hour of nativity in caſting up the events that are feigned to be deduced by the impoſters who pretend to that ſcience.

AMNITES, in mineralogy, ſignifies the Hammites or ſpawn ſtone. It was formerly conjectured, that this ſtone was produced from fiſh ſpawn; but the idea is now deſervedly exploded, as it is found to be a dropping or ſand petrefaction.

AMOEBÆUM, in ancient poetry, a kind of poem repreſenting a diſpute between two perſons, who are made to anſwer each other alternately: ſuch are the third and ſeventh of Virgil's eclogues.

AMOGLOSSUS, in ichthyology, is the ſame as the ſpecies of the ſoal fiſh, called the lantern, which is reckoned a delicious taſted fiſh.

AMOMI, in commerce, is a Dutch term, for what we call the Jamaica, or long pepper.

AMOMUM, GINGER, a genus of the monogynia order, belonging to the monandria claſs of plants. For the characters ſee Syſtem of BOTANY. Of this genus there are four ſpecies:

1. The zingiber, or common ginger, is a native of the Eaſt, and alſo of ſome parts of the Weſt Indies; where it grows naturally without culture. The roots are jointed, and ſpread in the ground: they put out many green reed-like ſtalks in the ſpring, which ariſe to the height of two feet and an half, with narrow leaves. The flower-ſtems ariſe by the ſide of theſe, immediately from the root; theſe are naked; ending with an oblong ſcaly ſpike. From each of theſe ſcales is produced a ſingle blue flower, whoſe petals are but little lower than the ſquamous covering.

2. The zerumbet, or wild ginger, is a native of India. The roots are larger than thoſe of the firſt, but are jointed in the ſame manner.

3. The cardamomum, or cardamom, is likewiſe a native of India; but little known in this country, except by its ſeeds, which are uſed in medicine.

4. The grana paradiſi ſpecies is likewiſe a native of the Eaſt Indies. It is more grateful, and conſiderably more pungent, than cardamoms.

The dried roots of the firſt ſpecies are of great uſe in the kitchen, as well as in medicine, and furniſh a conſiderable export from ſome of the American iſlands. The green roots, preſerved as a ſweetmeat, are preferable to every other kind.

Ginger is a very uſeful ſpice, in cold flatulent cholics, and in laxity and debility of the inteſtines; it does not heat ſo much as thoſe of the pepper kind, but its effects are much more durable. The cardamoms and grains of paradiſe have the ſame medicinal qualities with ginger. In Jamaica, the common people employ it in baths and fomentations with good ſucceſs, in complaints of the viſcera, in pleuriſies, and in obſtinate and continued fevers.

AMOMUM *Verum*, or *True Amomum*, is a round fruit, about the ſize of a middling grape; containing, under a membranous cover, a number of ſmall rough angular ſeeds, of a blackiſh brown colour on the outſide, and whitiſh within; the ſeeds are lodged in three diſtinct cells; thoſe in each cell are joined cloſely together, ſo as that the fruit, upon being opened, appears to contain only three ſeeds. Ten or twelve grow together in a cluſter; and adhere without any pedicle, to a woody ſtalk about an inch long; each fruit is ſurrounded by ſix leaves, in form of a cup; and the part of the ſtalk void of fruit is clothed with leafy ſcales. The huſks, leaves, and ſtems, have a light grateful ſmell, and a moderately warm aromatic taſte; the ſeeds, freed from the huſks, are in both reſpects much ſtronger; their ſmell is quick and penetrating, their taſte pungent, approaching to that of camphor.

AMOMUM *Vulgare*, the ſame as SISON.

AMORÆANS, a ſect or order of gemaric doctors, or commentators on the Jeruſalem Talmud. The Amoræans ſucceeded the Miſchnic doctors. They ſubſiſted 250 years; and were ſucceeded by the Seburæans.

AMORCE, in military matters, implies a fine clear-grained powder of rapid inflammation.

AMORE, in ichthyology, are of three kinds, all natives of Weſt Indian ſeas. 1. Amore pixuma. 2. Amore guaca. 3. Amore tinga. They are all eaten, but the firſt is the beſt.

AMORITES, a people deſcended from Amorrhæus, according to the Septuagint and Vulgate; Emoræus, according to other expoſitors; Hæmori, according to the Hebrew; or Emorite, according to our verſion of the bible; who was the fourth ſon of Canaan. Gen. x. 16.

The Amorites firſt of all peopled the mountains lying to the weſt of the Dead Sea. They had likewiſe eſtabliſhments to the Eaſt of the ſame ſea, between the brooks of Jabbock and Arnon, from whence they forced the Ammonites and Moabites. Numb. xiii. 30. xxi. 29. Joſh. v. 1. and Judges xi. 19, 20. Moſes made a conqueſt of this country from their kings Sihon and Og, in the year of the world 2553.

The prophet Amos, (ii. 9) ſpeaking of the gigantic ſtature and valour of the Amorites, compares their height with that of cedars, and their ſtrength with that of an oak. The name Amorite is often taken in Scripture for all Canaanites in general. The lands which the Amorites poſſeſſed on this ſide Jordan were given to the tribe of Judah, and thoſe which they enjoyed beyond this river, were diſtributed between the tribes of Reuben and Gad.

AMORPHA, False Indigo, a genus of the decandria order, belonging to the diadelphia claſs of plants; and, in the natural method, ranking under the 32d order, Papilionaceæ. For the characters ſee Syſtem of Botany.

Of this there is only one known ſpecies, a native of Carolina, where the inhabitants formerly made from it a coarſe kind of indigo, whence the plant took its name. It riſes, with many irregular ſtems, to the height of 12 or 14 feet. The leaves are late in the ſpring before the foliage is fully diſplayed. The ends of their branches are generally deſtroyed by the froſt; or, if they recover it, they have the appearance of being dead. They ſhew their leaves about the middle of May, which are of a pleaſant green colour, very large, beautifully pinnated, the ſolioles being arranged along the ſtalk by pairs, and terminate by an odd one. The flowers are of a purple colour, and ſhow themſelves in perfection the beginning of July. They grow in ſpikes, ſeven or eight inches long, at the ends of the branches, and are of a ſingular ſtructure. The ſeeds of this plant were firſt ſent to England by Mr. Mark Cateſby in 1724, from which many plants were raiſed in the gardens near London.

The amorpha is moſt readily propagated by ſeeds, which ought to be procured annually from America. It may alſo be propagated by laying down the young branches, which in one year will make good roots; and may then be taken off, and planted in the places where they are deſigned to remain.

AMORTIZATION, in law, the alienation of lands or tenements to a corporation or fraternity and their ſucceſſors.

AMOS, a canonical book of the Holy Scriptures; the prophecy is recorded as the work of one of the minor prophets, who was a herdſman at Tekoa, a ſmall town about twelve miles from Jeruſalem. The prophet remonſtrates with the Iſraelites firſt, and then the Samaritans, concerning the evils of their ways; and laſtly, pronounces God's judgment againſt each nation: and cloſes his works with the glad tidings of the kingdom of Chriſt.

AMOVING, in law, implies the removal of an unſociable inhabitant from one part of the realm to another, at the diſcretion of the court, or the pleaſure of the king.

By the ſtat. 1 W. and M. c. 9, papiſts were amoved (removed) out of London and Weſtminſter, and a circuit of ten miles round each.

AMPANA, in botany, a trivial name given to the boraſſus of Linnæus.

AMPER, or Ampor, a dialect term, which vulgarly implies a tumor or ſwelling.

AMPELIS, the vine, in botany, the ſame as Vitis.

Ampelis, the chatterer, in ornithology, a genus of birds belonging to the order of paſſeres; the diſtinguiſhing characters of which are, that the tongue is furniſhed with a rim or margin all round, and the bill is conical and ſtrait.

There are ſeven ſpecies, all natives of foreign countries, except the garrulus, which is a native both of Europe and the Weſt Indies. In the former, the native country of theſe birds is Bohemia; from whence they wander over the reſt of Europe, and were once ſuperſtitiouſly conſidered as preſages of a peſtilence.

They appear annually, in the northern parts of this kingdom, in February; and feed on the berries of the mountain-aſh. They are gregarious; feed on grapes, where vineyards are cultivated; are eaſily tamed; and eſteemed delicious food.

This ſpecies is about the ſize of the black-bird: the bill is ſhort, thick, and black; on the head is a ſharp-pointed creſt reclining backwards: the lower part of the tail is black; the end of a rich yellow: the quill feathers are black, the three firſt tipt with white; the ſix next have half an inch of their exterior margin edged with fine yellow, the interior with white.

They have horny appendages from the tips of ſeven of the ſecondary feathers, of the colour and gloſs of the beſt red wax.

AMPELITES, Canal, Cannel-coal, Candle-coal, or Black Silk Coal, a hard, opaque, foſſile, inflammable ſubſtance, of a black colour. It does not effervеſce with acids. The ampelites, though much inferior to jet in many reſpects, is yet a very beautiful foſſil; and, for a body of ſo compact a ſtructure, remarkably light. Examined by the microſcope, it appears compoſed of innumerable very ſmall and thin plates, laid cloſely and firmly on one another; and full of very ſmall ſpecks of a blacker and more ſhining matter than the reſt, which is evidently a purer bitumen than the general maſs. Theſe ſpecks are equally diffuſed over the different parts of the maſſes.

It is dug in many parts of England, and France. It makes a very briſk fire, flaming violently for a ſhort time, and after that continuing red and glowing hot a long time; and finally is reduced into a ſmall proportion of grey aſhes, the greater part of its ſubſtance having flown off in the burning. It is capable of a very high and elegant poliſh; and, in the countries where it is produced, is turned into a vaſt number of toys, which bear all the nicety of turning, and paſs for jet.

AMPHERES, in antiquity, a kind of veſſels wherein the rowers plied two oars at the ſame time, one with the right hand and the other with the left.

AMPHIATHROSIS, in anatomy, a term for ſuch junctures of bones as have an evident motion, but different from the diarthroſis, &c.

AMPHIARAUS, in pagan mythology, a celebrated prophet, who poſſeſſed part of the kingdom of Argos. He was believed to excel in divining by dreams, and is ſaid to be the firſt who divined by fire.

Amphiaraus knowing, by the ſpirit of prophecy, that he ſhould loſe his life in the war againſt Thebes, hid himſelf in order to avoid engaging in that expedition: but his wife Eriphyle, being prevailed upon by a preſent, diſcovered the place in which he had concealed himſelf; ſo that he was obliged to accompany the other princes who marched againſt Thebes. This proved fatal to him; for the earth being ſplit aſunder by a thunder-bolt, both he and his chariot were ſwallowed up in the opening.

Amphiaraus, after his death, was ranked among the gods; temples were dedicated to him; and his oracle, as well as the ſports inſtituted to his honour, were very famous.

AMPHIBIA, in zoology, the name of Linnæus's third claſs of animals; including all thoſe which live partly in water and partly on land. The characters of this claſs are: that they have either a naked, or elſe a ſcaly body, with no grinders, or dentes molares, their teeth all ſharp and pointed, and without radiated fins: their heart has but one ventricle, and they reſpire through their lungs.

This claſs is divided into three orders, namely; 1. Reptiles. 2. Serpents. 3. Swimming Amphibia. It comprehends 24 genera and 289 ſpecies.

It is not certain whether the animals commonly called *amphibious*, live moſt in the water or on land. If we conſider the words *αμφι* (*utrinque*, both ways), and *βιος* (*vita*, life), from which the term *amphibious* is derived; we ſhould underſtand, that animals having this title, ſhould be capable of living as well by land, or in the air, as by water; or of dwelling in either conſtantly at will: but it will be difficult to find any animal that can fulfil this definition, as being equally qualified for either. An ingenious naturaliſt, divides them into two orders, viz. 1. Such as enjoy their chief functions by land, but occaſionally go into the water. 2. Such as chiefly inhabit the water, but occaſionally go aſhore. That this diviſion is judicious will appear from the following obſervation:

Otters, beavers, and ſome kinds of rats, go occaſionally into the water for their prey, but cannot remain very long under water.

Frogs, how capable ſoever of remaining in the water, yet cannot avoid living on land; and if a frog be thrown into a river, he makes to the ſhore as faſt as he can.

The lizard kind, ſuch as may be called water-lizards, are all obliged to come to land, in order to depoſit their eggs, to reſt, and to ſleep. Even the crocodiles, who dwell much in rivers, ſleep and lay their eggs on ſhore; and, while in the water, are compelled to riſe to the ſurface to breathe; yet, from the texture of his ſcaly covering, he is capable of remaining in the water longer by far than moſt other amphibious animals.

The hippopotamus, who wades into the lakes or rivers, is a quadruped, and remains under the water a conſiderable time; yet its chief reſidence is upon land, and he muſt come on ſhore for reſpiration.

The teſtudo, or ſea-tortoiſe, though it goes out to ſea, and is often found far from land, yet being a reſpiring animal, cannot remain long under water.

Among the amphibious animals which chiefly inhabit the waters, but occaſionally go on ſhore, are, eels and water ſerpents, or ſnakes of every kind. It is their form that qualifies them for loco-motion on land, and they know their way back to the water at will; for by their ſtructure they have a ſtrong periſtaltic motion, by which they can go forward at a pretty good rate: whereas all other kinds of fiſh, whether vertical or horizontal, are incapable of a voluntary loco-motion on ſhore; and therefore, as ſoon as ſuch fiſh are brought out of the water, after having flounced a while, they lie montionleſs, and ſoon die.

All land animals have lungs, and can live no longer than while theſe are inflated by the ambient air, and alternately compreſſed for its expulſion; that is, while reſpiration is duly carried on, by a regular inſpiration and exſpiration of air.

In like manner, the fiſh in general have, inſtead of lungs, gills or branchiæ; and as in land animals the lungs have a large portion of the maſs of blood circulating through them, which muſt be ſtopped if the air has not a free ingreſs and egreſs into and from them; ſo, in fiſh, there is a great number of blood-veſſels that paſs through the branchiæ, and a great portion of their blood circulates through them, which muſt in like manner be totally ſtopped, if the branchiæ are not perpetually wet with water. So that, as the air is to the lungs in land animals a conſtant aſſiſtant to the circulation; ſo is the water to the branchiæ of thoſe of the rivers and ſeas: for when theſe are out of the water, the branchiæ very ſoon grow criſp and dry, the blood-veſſels are ſhrunk, and the blood is obſtructed in its paſſage; ſo, when the former are immerſed in water, or otherwiſe prevented from having reſpiration, the circulation ceaſes, and the animal dies.

Again, as land animals would be deſtroyed by too much maceration in water, ſo fiſhes would, on the other hand, be ruined by too much exſiccation; the latter being, from their general ſtructure and conſtitution, made fit to bear, and live in, the water; the former, by their conſtitution and form, to breath and dwell in the air.

AMPHIBIOUS, in natural hiſtory, imports much the ſame meaning as Amphibia; but may be defined generally to imply a term applied to a ſort of animals which live both upon land and in the water, i. e. which breathe the air, but paſs part of their time in the water, as affording them their chief food.

AMPHIBLESTROIDES, in anatomy, denotes a tunic, or coat of the eye, more uſually called the retina.

AMPHIBOLOGY, in grammar and rhetoric, a term uſed to denote a phraſe that admits of two different interpretations.

AMPHIBRACHYS, in ancient poetry, the name of a foot conſiſting of three ſyllables, whereof that in the middle is long, and the other two ſhort; ſuch is the word ăbīrĕ.

AMPHICOME, in natural hiſtory, a kind of figured ſtone, of a round ſhape, but rugged, and beſet with eminences, celebrated on account of its uſe in divination. The word is originally Greek, αμφικομη, *q. d. utrinque comata*, or "hairy on all ſides." This ſtone is alſo called *Erotylos*, Ερωτυλος, *Amatoria*, probably on account of its ſuppoſed power of creating love. The amphicome is mentioned by Democritus and Pliny, though little known among the moderns. Mercatus takes it for the ſame with the *lapis lumbricatus*, of which he gives a figure.

AMPHICTYONS, in Grecian antiquity, an aſſembly compoſed of deputies from the different ſtates of Greece; and reſembling, in ſome meaſure, the diet of the German empire.

The ſtated terms terms of their meeting was in ſpring and autumn; the ſpring meeting was called Εαρινη Πυλαια, that in autumn Μετοπωρινη. On extraordinary occaſions, however, they met at any time of the year, or even continued ſitting all the year round.

Philip of Macedon uſurped the right of preſiding in the aſſembly of the Amphictyons, and of firſt conſulting the oracle which was called Προμαντεια.

AMPHIDROMIA, a feaſt celebrated by the ancients on the fifth day after the birth of a child.

AMPHIDRYON, in eccleſiaſtical writers, denotes the veil or curtain which was drawn before the door of the bema in ancient churches.

AMPHIMACER, in ancient poetry, a foot conſiſting of three ſyllables, whereof the firſt and laſt are long, and that in the middle ſhort; ſuch is the word cāſtĭtās.

AMPHION, in mythology, the ſon of Jupiter and Antiope; who, according to the poets, made the rocks follow his muſic; and at his harp the ſtones of Thebes danced into walls and a regular city.

AMPHIMALLUM, in church hiſtory, denotes the wool-fleece, or coat of the biſhops; figuratively alluding to the garment of innocence, neceſſary for the ſhepherd of the flock.

AMPHIBNEUMA, in medicine, ſignifies the difficulty of reſpiration in pleuretic fevers, and other diſeaſes of the lungs.

AMPHIPOLES, in antiquity, the principal magiſtrates of Syracuſe. They were eſtabliſhed by Timoleon in the 109th Olympiad, after the expulſion of the tyrant Dyoniſius. They governed Syracuſe for the ſpace of 300 years: and Diodorus Siculus aſſures us they ſubſiſted in his time.

AMPHIPII, in Grecian antiquity, ſoldiers who, in war, uſed two horſes without ſaddles, and were dextrous enough to leap from one to the other.

AMPHIPORÆ, in the naval affairs of the ancients, were veſſels with a prow at each end. They were uſed chiefly in rapid rivers and narrow channels, where it was not eaſy to tack about.

AMPHIPROSTYLE, in the architecture of the ancients, a temple which had four columns in the front, and as many in the aſpect behind.

AMPHISBÆNA, in zoology, a genus of ſerpents belonging to the order of amphibia ſerpentes, ſo called from the falſe notion of its having two heads, becauſe it moves with either end foremoſt.

The head of the amphiſbæna is ſmall, ſmooth, and blunt; the noſtrils are very ſmall; the eyes are minute and blackiſh; and the mouth is furniſhed with a great number of ſmall teeth. The body is cylindrical, about a foot long, and divided into about 200 annular convex ſegments, like thoſe of a worm; and it has about 40 longitudinal ſtreaks, of which 12 on each ſide are in the form of ſmall croſſes like the Roman X; the anus is a tranſverſe ſlit; and the laſt ring, or ſegment of the belly, has eight ſmall papillæ, forming a tranſverſe line before the anus; the tail, i. e. all the ſpace below the anus, is ſhort, conſiſting of 30 annular ſegments, without being marked with the croſs-lines, and is thick and blunt at the point. The colour of the whole animal is black, variegated with white; but the black prevails moſt on the back, and the white on the belly. It has a great reſemblance to a worm, living in the earth, and moving equally well with either end foremoſt. There are but two ſpecies:

1. The fuliginoſa, which anſwers exactly to the above deſcription, and is found in Libya, and in different parts of America.

2. The alba, which is totally white, is a native of both the Indies, and is generally found in ant-hillocks. The bite of the amphiſbæna is reckoned to be mortal by many authors; but as it is not furniſhed with dog-fangs, the uſual inſtruments of conveying the poiſon of ſerpents, later writers eſteem it not to be poiſonous. They feed upon ants and earth-worms, but particularly the latter.

Amphisbæna Aquatica, a name given by Bertrutius, Albertus, and ſeveral other authors, to that long and ſlender inſect, called by others the ſeta aquatica, and vermis ſetarius. It has the name amphiſbæna, from its going backwards or forwards with equal eaſe and celerity. The uſual ſize is four or five inches long, and about the thickneſs of a large hair.

AMPHISCII, among geographers, a name applied to the people who inhabit the torrid zone. The Amphiſcii, as the word imports, have their ſhadows one part of the year towards the north, and the other towards the ſouth, according to the ſun's place in the ecliptic. They are alſo called Aſcii.

AMPHISMILA, or Amphismela, in ſurgery, a two-edged knife.

AMPHITAPAA, in antiquity, a cloth with a rug or knap on each ſide.

AMPHITANE, in natural hiſtory, a ſtone ſaid to attract gold as the loadſtone does iron. Pliny ſays it was found in that part of the Indies where the native gold lay ſo near the ſurface of the earth, as to be turned up in ſmall maſſes among the earth of ant-hills; and deſcribes it to have been of a ſquare figure, and of the colour and brightneſs of gold. The deſcription plainly points out a well-known foſſil, called, by Dr. Hill, *pyricubium*: this is common in the mines of moſt parts of the world; but neither this, nor any other ſtone, was ever ſuppoſed, in our times, to have the power of attracting gold.

AMPHITHEATRE, in antiquity, a ſpacious edifice, built either round or oval, with a number of riſing ſeats, upon which the people uſed to behold the combats of gladiators, of wild beaſts, and other ſports.

Amphitheatres were at firſt only of wood; and it was not till the reign of Auguſtus, that Statilius Taurus built one, for the firſt time, of ſtone. The loweſt part was of an oval figure, and called *arena*, becauſe, for the convenience of the combatants, it was uſually ſtrewed with ſand; and round the arena were vaults, ſtyled *caveæ*, in which were confined the wild beaſts appointed for the ſhows.

Above the caveæ was erected a large circular periſtyle, or podium, adorned with columns. This was the place of the emperors, ſenators, and other perſons of diſtinction.

The rows of benches were above the podium. Their figure was circular; and they were entered by avenues, at the end of which were gates called *vomitoriæ*.

The Theatre was built in orm of a ſemicircle, only exceeding a juſt ſemicircle by one fourth part of the diameter; and the amphitheatre was nothing elſe but a double theatre, or two theatres joined together: ſo that the longeſt diameter of the amphitheatre was to the ſhorteſt as 1½ to 1.

There are amphitheatres ſtill ſtanding at Rome, at Pola, at Niſmes, &c. The amphitheatre of Veſpaſian, called the *coliſeum*, and that at Verona, in Italy, are the moſt celebrated now remaining of all antiquity. Remains of amphitheatres are ſhown alſo at Arles, Bourdeaux, &c. The amphitheatre of Veſpaſian is computed to have been capable of holding 87,000 ſpectators.

Amphitheatre, in gardening, certain diſpoſitions of trees and ſhrubs on the ſides of hilly places, which, if the hill or riſing be naturally of a circular figure, always have the beſt effect. They are formed of ever-greens, ſuch as hollies, phillereys, laureſtines, bays, and ſuch plants, obſerving to plant the ſhorteſt growing trees in the front, and thoſe which will be the talleſt behind, ſuch as pines, firs, cedars, &c.

Amphitheatres are alſo ſometimes formed of ſlopes on the ſides of hills, covered only with turf; and, when well kept, they are a great ornament to large gardens.

AMPHITHURA, in antiquity, ſignified the veil which divided the chancel from the reſt of the church.

AMPHITRITE, αμφιτριτη, from *circumferendo*, in the heathen mythology, the wife of Neptune, and goddeſs of the ſea, ſometimes taken for the ſea: alſo the name of a ſmall naked ſea inſect, ſomewhat reſembling a quill.

AMPHITRYON, in mythology, ſon of Alcæus, leſs known by his own exploits than from his wife Alcmena's adventure.

AMPHODONTA, in zoology, a deſignation given to animals which have teeth in both jaws, i. e. upper and under.

AMPHORA, in antiquity, a liquid meaſure among the Greeks and Romans. The Roman amphora contained 48 ſextaries, equal to about ſeven gallons one pint Engliſh wine-meaſure; and the Grecian or Attic amphora contained one-third more.

Amphora was alſo a dry meaſure uſed by the Romans, and contained about three buſhels.

Amphora, among the Venetians, is the largeſt meaſure uſed for liquids, containing about 16 quarts.

AMPHORARIUM Vinum, in antiquity, denotes that which is drawn or poured into *amphoræ* or pitchers; by way of diſtinction from *vinum doliare*, or caſk wine. The Romans had a method of keeping wine in *amphoræ*, for many years, to ripen, by faſtening the lids tight down with pitch or gypſum, and placing them either in a ſituation where the ſmoke came, or under ground.

AMPHOTEROPLON, in civil law, denotes a naval inſurance on ſhipping, in outward bound, and returning voyages, generally diſtinguiſhed from Heteroplon, or voyages only inſured for the outfit, or export deſtination.

AMPHOTIDES, in antiquity, a kind of armour or covering for the ears, worn by the ancient pugiles, to prevent their adverſaries from laying hold of thoſe parts.

AMPLEXATIO, in alchemy, denotes the connexion or union of the philoſophical mercury, as male and female; the former red, the latter white.

AMPLIATION, in a general ſenſe, denotes the act of enlarging or extending the compaſs of a thing.

On a medal of the emperor Antoninus Pius, we find the title *ampliator civium* given him, on account of his having extended the *jus civitatis*, or rights of citizens, to many ſtates and people before excluded that privilege.

Ampliation, in Roman antiquity, was the deferring to paſs ſentence in certain cauſes. This the judge did by pronouncing the word *amplius*; or by writing the letters N. L. for *non liquet*; thereby ſignifying, that, as the cauſe was not clear, it would be neceſſary to bring further evidence.

AMPLIFICATION, in rhetoric, part of a diſcourſe or ſpeech, wherein a crime is aggravated, a praiſe or commendation heightened, or a narration enlarged, by an enumeration of circumſtances; ſo as to excite the proper emotions in the ſouls of the auditors. Such is the paſſage in Virgil, where, inſtead of ſaying merely that Turnus died, he amplifies the circumſtances of his death.

> *—Aſt illi ſolvuntur frigore membra,*
> *Vitaque cum gemitu fugit indignata ſub umbras.*

Elegant ſpeakers make amplification to be the ſoul of diſcourſe.

AMPLITUDE, in aſtronomy, an arch of the horizon, intercepted between the eaſt or weſt point and the centre of the ſun, or a planet, at its riſing or ſetting; and ſo is either north and ſouth, or ortive and occaſive.

Magnetical Amplitude, the different riſing or ſetting of the ſun, from the eaſt or weſt points of the compaſs. It is found by obſerving the ſun at his riſing and ſetting, by an amplitude-compaſs.

AMPOTIS, in natural hiſtory, ſignifies the receſs or ebb of the tide. Hence phyſicians, from the great Hippocrates, call an abatement of any diſorder, an ampotis or receſs.

AMPULLA, in antiquity, a round big-bellied veſſel, which the ancients uſed in their baths, to contain oil for anointing their bodies. Alſo the name of a cup for drinking out of at table.

Ampulla, among eccleſiaſtical writers, denotes one of the ſacred veſſels uſed at the altars. Ampullæ were alſo uſed for holding the oil uſed in chriſmation, conſecration, coronation, &c.

Knights of St. Ampulla, belong to an order inſtituted by Clovis I. king of France; at the coronation they bear up the canopy, under which the ampulla is carried in proceſſion.

AMPUTATION, in ſurgery, the cutting off a limb, or any part from the body. For the method ſee Syſtem of Surgery.

AMSEGETES, in ancient law books, denoted thoſe whoſe lands abutted on the king's highway.

AMTRUSTIO, in ancient charters, denotes a ſworn fidelity from the tenant to his lord.

AMULET, a charm, or pretended preſervative againſt miſchief, witchcraft, or diſeaſes.

Amulets were made of ſtone, metal, ſimples, animals, and in a word of every thing that imagination ſuggeſted.

Sometimes they conſiſted of words, characters, and ſentences, ranged in a particular order, and engraved upon wood, &c. and worn about the neck, or ſome other part of the body.

At other times they were neither written or engraved; but prepared with many ſuperſtitious ceremonies, great regard being uſually paid to the influence of the ſtars. The Arabians have given to this ſpecies of amulet the name of Talisman.

All nations have been fond of amulets: the Jews were extremely ſuperſtitious in the uſe of them, to drive away diſeaſes; and the Miſna forbids them, unleſs received from an approved man who had cured at leaſt three perſons before by the ſame means.

Among the Chriſtians of the early times, amulets were made of wood, or ribbands with a text of Scripture written on them, as preſervatives againſt diſeaſes. They are now very properly exploded, and looked upon fictions to impoſe upon mankind, which in truth they certainly were.

AMULETIC *Medicines*, implies medical ſuperſtition.

AMUND, in antiquity, denotes a perſon of age, and fully inſtructed.

AMURCA, in pharmacy, denotes a drying medicine.

AMYGDALUS, the Almond and Peach, a genus of the monogynia order, belonging to the icoſandria claſs of plants; and, in the natural method, ranking under the 36th order, Pomaceæ. For the characters, ſee Syſtem of Botany.

There are enumerated ſeveral ſpecies, 1. The Communis, or Common Almond, a native of Africa, will grow to near 20 feet high; and whether planted ſingly in an open place, or mixed with others in clumps, ſhrubbery-quarters, &c. ſhews itſelf one of the fineſt flowering trees in nature. The white flowering almond, well known in our nurſeries, is a variety of this ſpecies, and is cultivated for the ſake of the flowers and the fruit.

2. The Nana, Dwarf Almond, is a native of Aſia Minor. Of this ſhrub there are two ſorts, the ſingle and the double. Both grow to about four or five feet high, and are in the firſt eſteem as flowering ſhrubs.

3. The Perſica, or Peach, is ſaid to be a native of Europe; but of what place is not known. Cultivation has produced many varieties of this fruit; of which the following are the moſt eſteemed.

1. The White Nutmeg.
2. The Red Nutmeg.
3. The Early Purple.
4. The Small Mignon.
5. The White Magdalen.
6. The Yellow Alberge.
7. The Large French Mignon.
8. The Beautiful Chevreuſe.
9. The Red Magdalen.
10. The Chancellor.
11. Smith's Newington.
12. The Montauban.
13. The Malta.
14. The Vineuſe.
15. The Bellegarde.
16. The Bourdine.
17. The Roſſanna.
18. The Admirable.
19. The Old Newington.
20. The Royal.
21. The Rambouillet.
22. The Portugal.
23. The Late Admirable.
24. The Nivette.
25. Venus's Nipple.
26. The late Purple.
27. The Perſique.
28. The Catharine.
29. The Monſtrous Pavy.
30. The Bloody Peach.

The White Nutmeg is the firſt peach in ſeaſon, it being often in perfection by the end of July. The leaves are doubly ſerrated, the flower large, and of a pale colour; the fruit is white, ſmall, and round; the fleſh too is white, parts from the ſtone, and has a ſugary, muſky flavour.

The Red Nutmeg hath yellowiſh green leaves, with ſerpentine edges, which are ſlightly ſerrated. The flowers are large, open, and of a deep bluiſh-colour. The fruit is larger and rounder than the former, and is of a bright vermilion next the ſun, but more yellow on the other ſide. The fleſh is white, except next the ſtone, from which it ſeparates, and has a rich muſky flavour. It ripens juſt after the white nutmeg.

The Early Purple hath ſmooth leaves, terminated in a ſharp point. The flowers are large, open, and of a lively red. The fruit is large, round, and covered with a fine deep red coloured down. The fleſh is white, red next the ſtone, and full of a rich vinous juice. Ripens about the middle of Auguſt.

The Small Mignon hath leaves ſlightly ſerrated, and the flowers ſmall and contracted. The peach is round, of a middling ſize, tinged with darkiſh red on the ſunſide, and is of a pale yellowiſh colour on the other. The fleſh is white, parts from the ſtone, where it is red, and contains plenty of a vinous, ſugary juice. Ripens rather before the former.

The White Magdalen hath long, ſhining, pale-green leaves, deeply ſerrated on the edges, and the wood is moſt black at the pith. The fruit is round, large, of a yellowiſh-white colour, except on the ſunny ſide, where it is ſlightly ſtreaked with red. The fleſh is white to the ſtone, from which it ſeparates, and the juice is pretty well flavoured. Ripe at the end of Auguſt.

The Yellow Alberge hath deep red, middle-ſized flowers: the peach is ſmaller than the former, of a yellow colour on the ſhady ſide, and of a deep red on the other. The fleſh is yellow, red at the ſtone, and the juice is ſugary and vinous.

The Great French Mignon hath large, finely ſerrated leaves, and beautiful red flowers. The fruit is large, quite round, covered with a fine ſattiny down, of a browniſh red colour on the ſunny ſide, and of a greeniſh yellow on the other. The fleſh is white, eaſily parts from the ſkin, and is copiouſly ſtored with a ſugary high-flavoured juice. Ripe near the middle of Auguſt.

The Beautiful Chevreuſe hath plain leaves, and ſmall contracted flowers. The fruit is rather oblong, of a middling ſize, of a fine red colour next the ſun, but yellow on the other ſide. The fleſh is yellowiſh, parts from the ſtone, and is full of a rich ſugary juice. ripens a little after the former.

The Red Magdalen hath deeply ſerrated leaves, and large open flowers. The fruit is large, round, and of a fine red next the ſun. The fleſh is firm, white, ſeparates from the ſtone, where it is very red: the juice is ſugary, and of an exquiſite rich flavour. Ripe at the end of Auguſt.

The Chancellor hath large, ſlightly ſerrated leaves. The peach is about the ſize of the Beautiful Chevreuſe, but rather rounder. The ſkin is very thin, of a fine red on the ſunny ſide; the fleſh is white and melting, parts from the ſtone, and the juice is very rich and ſugary. It ripens with the former.

The leaves of Smith's Newington are ſerrated, and the flowers are large and open. The fruit is of a middle ſize, of a fine red on the ſunny ſide; the fleſh white and firm, but very red at the ſtone, to which it ſticks cloſely, and the juice has a pretty good flavour. Ripens with the former.

The Montauban hath ſerrated leaves, and large open flowers.
The

The fruit is about the ſize of the former, of a purpliſh red next the ſun, but of a pale one on the ſhady ſide. The fleſh is melting and white even to the ſtone, from which it ſeparates. The juice is rich, and well flavoured. It ripens a little before the former.

The Malta hath deeply ſerrated leaves, and the flowers are large and open. The fruit is almoſt round, of a fine red next the ſun, marbled with a deeper red, but the ſhady ſide is of a deep green. The fleſh is fine, white, except at the ſtone, from which it parts, where it is of a deep red; the juice is a little muſky, and agreeable. It ripens at the end of Auguſt, or beginning of September.

The Vineuſe hath large deep green leaves, and full bright red flowers. The fruit is round, of a middle ſize; the ſkin is thin, all over red; the fleſh fine and white, except at the ſtone, where it is very red, and the juice is copious and vinous. Ripe in the middle of September.

The Bellegarde hath ſmooth leaves, and ſmall contracted flowers. The fruit is very large, round, and of a deep purple colour next the ſun. The fleſh is white, parts from the ſtone, where it is of a deep red, and the juice is rich and excellent. It ripens early in September.

The Bourdine hath large, fine green, plain leaves, and ſmall fleſh-coloured contracted flowers. The fruit is round, of a dark red next the ſun; the fleſh white, except at the ſtone, where it is of a deep red, and the juice is rich and vinous. Ripens with the former.

The Roſſanna hath plain leaves, and ſmall contracted flowers. The fruit is rather longer than the alberge, and ſome count it only a variety of the latter. The fleſh is yellow, and parts from the ſtone, where it is red; the juice is rich and vinous. Ripe early in September.

The Admirable hath plain leaves, and ſmall contracted flowers, which are of a pale red. The fruit is very large and round; the fleſh is firm, melting, and white, parts from the ſtone, and is there red; and the juice has a ſweet, ſugary, high vinous flavour. Ripe early in September.

The Old Newington hath ſerrated leaves, and large open flowers. The fruit is large, of a fine red next the ſun; the fleſh is white, ſticks cloſe to the ſtone, where it is of a deep red, and the juice has an excellent flavour. It ripens juſt after the former.

The Royal has plain leaves, and ſmall contracted flowers. The fruit is about the ſize of the admirable, and reſembles it, except that it has ſometimes a few knobs or warts. The fleſh is white, melting, and full of a rich juice; it parts from the ſtone, and is there of a deep red. Ripe about the middle of September.

The Rambouillet hath leaves and flowers like the royal. The fruit is rather round than long, of a middling ſize, and deeply divided by a furrow. It is of a bright yellow on the ſhady ſide, but of a fine red on the other. The fleſh is melting, yellow, parts from the ſtone, where it is of a deep red, and the juice is rich and vinous. Ripe with the former.

The Portugal hath plain leaves, and large open flowers. The fruit is large, ſpotted, and of a beautiful red on the ſunny ſide. The fleſh is firm, white, ſticks to the ſtone, and is there red. The ſtone is ſmall, deeply furrowed, and the juice is rich and ſugary. Ripe towards the end of September.

The Late Admirable hath ſerrated leaves, and browniſh red ſmall contracted flowers. The fruit is rather large and round, of a bright red next the ſun, marbled with a deeper. The fleſh is of a greeniſh white, and ſticks to the ſtone, where it hath ſeveral red veins; the juice is rich and vinous. Ripe about the middle of September.

The Nivette hath ſerrated leaves, and ſmall contracted flowers. The fruit is large and roundiſh, of a bright red colour next the ſun, but of a pale yellow on the ſhady-ſide. The fleſh is of a greeniſh-yellow, parts from the ſtone, where it is very red, and is copiouſly ſtored with a rich juice. It ripens about the middle of September.

Venus's Nipple hath fine ſerrated leaves, and roſe-coloured, ſmall contracted flowers, edged with carmine. The fruit is of a middling ſize, and has a riſing like a breaſt. It is of a faint red on the ſun-ſide, and on the ſhady one of a ſtraw-colour. The fleſh is melting, white, ſeparates from the ſtone, where it is red, and the juice is rich and ſugary. Ripens late in September.

The Late Purple hath large, ſerrated leaves, which are variouſly contorted, and the flowers are ſmall and contracted. The fruit is round, large, of a dark red on the ſunny-ſide, and yellowiſh on the other. The fleſh is melting, white, parts from the ſtone, where it is red, and the juice is ſweet and high-flavoured. Ripens with the former.

The Perſique hath large, very long indented leaves, and ſmall contracted flowers. The fruit is large, oblong, of a fine red next the ſun; the fleſh firm, white but red at the ſtone, juicy, and of a high pleaſant flavour. The ſtalk has frequently a ſmall knot upon it. Ripe late in September.

The Catharine hath plain leaves, and ſmall flowers. The fruit is large, round, of a very dark red next the ſun. The fleſh white, firm, ſticks cloſe to the ſtone, and is there of a deep red. The juice is rich and pleaſant. It ripens early in October.

The Monſtrous Pavy hath large, very ſlightly ſerrated leaves, and large, but rather contracted flowers. The fruit is round, and very large, whence its name. It is of a fine red on the ſunny ſide, and of a greeniſh-white on the other. The fleſh is white, melting, ſticks cloſe to the ſtone, and is there of a deep red. It is pretty full of juice, which in dry ſeaſons is ſugary, vinous, and agreeable. Ripe towards the end of October.

The peach-tree has hitherto been planted againſt a wall; and if they are well managed, by this advantage, they are ſucceeded by very good fruit.

The Bloody Peach hath rather large, ſerrated leaves, which turn red in autumn. The fruit is of a middling ſize, the ſkin all over of a dull red, and the fleſh is red down to the ſtone. The fruit is but dry, and the juice rather ſharp and bitteriſh. It ſeldom ripens well in England, but is well worth cultivating notwithſtanding, for the fruit bake and preſerve excellent well.

The Nectarine, according to Linnæus, is only a variety of the peach, its having a ſmooth coat being only an accident originally. Of this alſo many varieties are now cultivated; and the following are ſome of the moſt eſteemed: 1. The Elruge. 2. The Newington. 3. The Scarlet. 4. The Roman. 5. The Murrey. 6. The Italian. 7. The Golden. 8. The Temple's.

The Elruge hath large ſerrated leaves, and ſmall flowers. The fruit is of a middling ſize, of a dark purple colour next the ſun, and of a greeniſh yellow on the ſhady ſide. The fleſh parts from the ſtone, and has a ſoft, melting, good flavoured juice. Ripe early in Auguſt.

The Newington hath ſerrated leaves, and large open flowers. The fruit is pretty large, of a beautiful red on the ſunny ſide, but of a bright yellow on the other. The fleſh ſticks to the ſtone, is there of a deep red colour, and the juice has an excellent rich flavour. Ripe towards the end of Auguſt.

The Scarlet is rather leſs than the former, of a fine ſcarlet colour next the ſun, but fades to a pale red on the ſhady ſide. It ripens near the time of the former.

The Roman, or cluſter red Nectarine, hath plain leaves, and large flowers. The fruit is large, of a deep red towards the ſun, but yellowiſh on the ſhady ſide. The fleſh is firm, ſticks to the ſtone, and is there red; the juice is rich, and has an excellent flavour. Ripe about the end of Auguſt.

The Murrey is a middling-ſized fruit, of a dirty red colour on the ſunny ſide, and yellowiſh on the ſhady one. The fleſh is firm, and tolerably well flavoured. It ripens early in September.

The Italian Nectarine hath ſmooth leaves and ſmall flowers; the fruit is red next the ſun, but yellowiſh on the other ſide; fleſh firm, adheres to the ſtone, where it is red, and when ripe, which is early in September, has an excellent flavour.

The Golden Nectarine has an agreeable red colour next the ſun, bright yellow on the oppoſite ſide; fleſh very yellow, ſticks to the ſtone, where it is of a pale red, has a rich flavour, and ripens in September.

Temple's Nectarine is of a middling ſize, of a fair red next the ſun, of a yellowiſh green on the other ſide; fleſh white near the ſtone, from which it ſeparates; ripens in September, and has a high poignant flavour.

All the above ſpecies are propagated by inoculating them into plum-ſtocks in Auguſt.

There are general rules given for the pruning of peach and nectarine trees; viz. 1. Always to have enough of bearing wood; and, 2. Not to lay in the branches too cloſe to one another.

Sweet almonds are reckoned to afford little nouriſhment; and, when eaten in ſubſtance, are not eaſy of digeſtion, unleſs thoroughly comminuted: Peeled, and eaten ſix or eight at a time, they ſometimes give preſent relief in the heart-burn. But in medicine they are moſtly uſed for making emulſions; and they abound not only with an oil, but likewiſe with a mucilage fit for incorporating oil and water together.

The bitter almonds are not now ſo much uſed as formerly, being found to be very unwholeſome.

As to the peach and nectarine, they are known to be delicious fruits.

Peach-flowers have an agreeable ſmell, and a bitteriſh taſte; diſtilled, without any addition, by the heat of a water-bath, they yield one-ſixth their weight, or more, of a whitiſh liquor, which communicates, to a large quantity of other liquids, a flavour like that of the kernels of fruits. An infuſion, in water, of half an ounce of the freſh-gathered flowers, or a drachm of them when dried, ſweetened with ſugar, proves for children an uſeful laxative and anthelmintic: the leaves of the tree are, with this intention, ſomewhat more efficacious, though leſs agreeable.

The fruit has the ſame quality with the other ſweet fruits, that of abating heat, quenching thirſt, and gently looſening the body.

AMYGDALATE, implies, in medicine, the milk or emulſion extracted from almonds.

AMYGDALOIDES Lapis, in mineralogy, denotes a kind of ſtone, produced from the petrefaction of the ſpine of the echinus marininus, or ſea urchin.

AMYLUM, in commercial manufacture, ſignifies ſtarch.

AMYNTICA Emplastra, in medical preſcriptions, denotes ſtrengthening plaſters.

AMYLACEOUS, from *amylum*, ſtarch; a term applied to the fine flour of farinaceous ſeeds, in which conſiſts their nutritive part.

AMYNTA, in literary hiſtory, a beautiful paſtoral comedy, compoſed by Taſſo; the model of all dramatic pieces wherein ſhepherds are actors.

AMYNTOR, *αμυντωρ*, formed of the verb *αμυνω*, *I defend*, or *avenge*, properly denotes a perſon who defends or vindicates a cauſe.

AMYRALDISM, a name given, by ſome writers, to the doctrine of univerſal grace, as explained and aſſerted by Amyraldus, or Moſes Amyrault, and his followers, among the reformed in France, towards the middle of the 17th century.

The principles of his doctrine were, that God deſires the happineſs of all men, and none are excluded by a divine decree; that none can obtain ſalvation without faith in Chriſt; that God refuſes to none the power of believing, though he does not grant to all his aſſiſtance, that they may improve this power to ſaving purpoſes; and that many periſh through their own fault. Thoſe who embraced this doctrine were called Univerſaliſts.

AMYRIS, in botany, a genus of the monogynia order, belonging to the decandria claſs of plants. For the characters ſee Syſtem of BOTANY. The moſt remarkable ſpecies are:

1. The elemifera, or ſhrub which bears the gum emeli, a native of South America. It grows to the height of about ſix feet, producing trifoliated ſtiff ſhining leaves, growing oppoſite to one another, on footſtalks two inches long. At the ends of the branches grow four or five ſlender ſtalks ſet with many very ſmall white flowers.

2. The gileadenſis, or opobalſamum, is an evergreen ſhrub, growing ſpontaneouſly in Arabia Felix, from whence the opobalſam, or balm of gilead, is procured.

3. Toxifera, or poiſon-wood, is a ſmall tree, with a ſmooth light-coloured bark. Its leaves are winged; the middle rib is ſeven or eight inches long, with pairs of pinnæ one againſt another, on inch-long footſtalks. The fruit hangs in bunches, is ſhaped like a pear, and is of a purple colour, covering an oblong hard ſtone. It grows uſually on rocks, in Providence, Ilathera, and others of the Bahama iſlands.

4. The balſamifera, or roſe-wood, is found on gravelly hills in Jamaica, and others of the Weſt-India iſlands.

From the firſt ſpecies, which is called by the natives of the Braſils, icicariba, is obtained the reſin improperly called gum elemi, or gum lemon. This drug is brought to us from the Spaniſh Weſt Indies, and ſometimes from the Eaſt Indies, in long roundiſh cakes, generally wrapped up in flag leaves. It almoſt totally diſſolves in pure ſpirit, and ſends over ſome part of its fragrance along with this menſtruum in diſtillation.

The ſecond ſpecies yields the balſam of Mecca, of Syria, or of Gilead, which is the moſt fragrant and pleaſant of any of the balſams.

ANA, among phyſicians, denotes a quantity equal to that of the preceding ingredient. It is abbreviated thus, āā, or ā.

ANA, in matters of literature, a Latin termination, adopted into the titles of ſeveral books in other languages. Anas, or books in ana, are collections of the memorable ſayings of perſons of wit and learning.

ANABAPTISM, in the doctrine of modern reformation in religion, imports the whole of the conſtitutional principles of the proteſtant ſectary, uſually denominated anabaptiſts.

ANABAPTISTON, the ſame with ABAPTISTON.

ANABAPTISTS, a name which has been indiſcriminately applied to Chriſtians of very different principles and practices; though many of them object to the denomination, and hold nothing in common, beſides the opinion that baptiſm ought always to be performed by immerſion, and not adminiſtered before the age of diſcretion.

The word Anabaptiſt is compounded of *ανα*, new, and *βαπτιςης*, a baptiſt; and in this ſenſe the Novatians, the Cataphrygians, and the Donatiſts, may be conſidered as a kind of Anabaptiſts in the earlier ages, though not then denoted by this name.

The Engliſh and Dutch Baptiſts do not conſider the denomination as at all applicable to their ſect: by whom the baptiſm appointed by Chriſt is held to be "nothing ſhort of *immerſion, upon a perſonal profeſſion of faith*;" of which profeſſion infants being incapable, and ſprinkling being no adequate ſymbol of the thing intended, the baptizing of proſelytes to their communion, who in their infancy had undergone the ceremony of ſprinkling, cannot, it is urged, be interpreted a repetition of the baptiſmal ordinance.

Anabaptiſts, in a ſtrict and proper ſenſe, appear to be thoſe who not only re-baptize, when they arrive at an adult age, perſons that were baptiſed in their infancy, but alſo, as often as any perſon comes from one of their ſects to another, or as often as any one is excluded from their communion and again received into the boſom of their church, they baptize him. But the opinion common to all the ſects to which the name of Anabaptiſts has been indiſcriminately applied, is that of the invalidity of infant baptiſm, in whatever way adminiſtered: and hence the general denomination of Antipædobaptiſts; which includes Anabaptiſts, Baptiſts, Mennonites, Waterlandians, &c. as diſtinguiſhed by their reſpective peculiarities; though Anabaptiſts ſeem to have been adopted by moſt writers as the general term.

The Anabaptiſts appear to have been little noticed before the time of reformation in Germany. The moſt prudent and rational part of them conſidered it poſſible, by human wiſdom, induſtry, and vigilance, to purify the church from the contagion of the wicked, provided the manners and ſpirit of the primitive Chriſtians could but recover their loſt dignity and luſtre; and ſeeing the attempts of Luther, ſeconded by ſeveral perſons of eminent piety, prove ſo ſucceſsful, they hoped that the happy period was arrived, in which the reſtoration of the church to purity was to be accompliſhed, under the divine protection, by the labours and counſels of pious and eminent men.

Others, far from being ſatisfied with the plan of reformation propoſed by Luther, looked upon it as much beneath the ſublimity of their views; and, conſequently, undertook a more perfect reformation, to found a new church, entirely ſpiritual, and truly divine.

This ſect was ſoon joined by great numbers, whoſe characters and capacities were very different, though their views ſeemed to turn upon the ſame object. Their progreſs was rapid; for, in a very ſhort ſpace of time, their diſcourſes, viſions, and predictions, excited commotions in a great part of Europe, and drew into their communion a prodigious multitude, whoſe ignorance rendered them eaſy victims to the illuſions of enthuſiaſm.

The moſt pernicious faction of all thoſe which compoſed this multitude, was that which pretended that the founders of the new and perfect church, already mentioned, were under the direction of a divine impulſe, and armed againſt all oppoſition, by the power of working miracles. This faction, in the year 1521, began their fanatical work, under the guidance of Munzer, Stubner, and Storck, who were diſciples of Luther; but well knowing that their opinions were ſuch as would receive no ſanction from him, they availed themſelves of his abſence to diſſeminate them in Wittemburgh, and had the addreſs to over-reach the piety of Melancthon. Their principal purpoſe was to gain over the populace, and to form a conſiderable party.

Storck, wanting knowledge, boaſted of inſpiration; and Stubner, who had both genius and erudition, laboured at commodious explications of Scripture. Not content with diſcrediting the court of Rome, and decrying the authority of conſiſtories, they taught, That among Chriſtians, who had the precepts of the goſpel to direct, and the ſpirit of God to guide them, the office of magiſtracy was not only unneceſſary, but an unlawful encroachment on their ſpiritual liberty; that the diſtinctions occaſioned by birth, or rank, or wealth, being contrary to the ſpirit of the goſpel, which conſiders all men as equal, ſhould be entirely aboliſhed; that all Chriſtians, throwing their poſſeſſions into one common ſtock, ſhould live together in that ſtate of equality which becomes members of the ſame family; that, as neither the laws of nature, nor the precepts of the New Teſtament, had placed any reſtraint upon men with regard to the number of wives which they might marry, they ſhould uſe that liberty which God himſelf had granted to the patriarchs.

At firſt they preached, exhorted, admoniſhed, and reaſoned, in a manner that ſeemed proper to impreſs the multitude; and related a great number of viſions and revelations, with which they pretended to have been favoured from above. But when they ſaw that theſe methods of making proſelytes were not attended with ſuch a rapid ſucceſs as they fondly expected, and that the miniſtry of Luther, and other eminent reformers, were detrimental to their cauſe, they then had recourſe to more expeditious meaſures, and madly attempted to propagate their fanatical doctrine by force of arms.

Munzer and his aſſociates, in the year 1525, put themſelves at the head of a numerous army, compoſed, for the moſt part, of the peaſants of Suabia, Thuringia, Franconia, and Saxony, and declared war againſt all laws, government, and magiſtrates of every kind, under the chimerical pretext that Chriſt was now to take the reins of civil and eccleſiaſtical government into his own hands, and to rule alone over the nations. But this ſeditious crowd was routed and diſperſed without much difficulty, by the Elector of Saxony and other princes; and Munzer, their ringleader, ignominiouſly put to death, and his factious counſellors ſcattered abroad in different places.

Many of his followers, however, ſurvived, and propagated their opinions through Germany, Switzerland, and Holland. In the year 1533, a party of them ſettled at Munſter under the direction of two Anabaptiſt prophets, John Matthias, a baker of Haerlem, and John Bockholdt, a journeyman taylor of Leyden.

Having made themſelves maſters of the city, they depoſed the magiſtrates, confiſcated the eſtates of ſuch as had eſcaped, and depoſited the wealth they amaſſed together in a public treaſury, for common uſe. They made preparations of every kind for the defence of the city; and ſent out emiſſaries to the Anabaptiſts in the Low Countries, inviting them to aſſemble at Munſter, which was now dignified with the name of Mount Sion, that from hence they might be deputed to reduce all the nations of the earth under their dominion.

Matthias, who was the firſt in command, was ſoon cut off, in act of frenzy, by the biſhop of Munſter's army; and was ſucceeded by Bockholdt, who was proclaimed by a ſpecial deſignation of Heaven, as he pretended, king of Sion, and inveſted with legiſlative powers, like thoſe of Moſes.

The extravagancies of Bockholdt were too numerous to be recited: it will be ſufficient to add, that the city of Munſter was taken after a long ſiege, and an obſtinate reſiſtance; and Bockholdt, the mock monarch, was puniſhed with a moſt painful and ignominious death.

It muſt be acknowledged, that the true riſe of the numerous inſurrections of this period, ought not to be attributed to religious opinions. The firſt inſurgents groaned under the moſt grievous oppreſſions: they took up arms principally in defence of their civil liberties; and of the commotions that took place. The Anabaptiſt leaders above mentioned ſeem rather to avail themſelves, than to have been the prime movers.

That a great part of the main body, indeed, conſiſted of Anabaptiſts, ſeems indiſputable; and whatever fanaticiſm exiſted among them would naturally be called forth, or be inflamed by the ſituations that occurred, and run riot in its wildeſt ſhapes. At the ſame time it appears from hiſtory, that vaſt numbers were concerned in thoſe inſurrections, of whom it is reported 100,000 fell by the ſword; it is, therefore, reaſonable to conclude, that a great majority of them were not Anabaptiſts.

It is to be remarked, that the Baptiſts or Mennonites in England and Holland are to be conſidered in a very different light from the enthuſiaſts we have been deſcribing: and it appears equally uncandid and invidious, to trace up their diſtinguiſhing ſentiment, as ſome of their adverſaries have done, to thoſe obnoxious characters, and there to ſtop, in order, as it were, to aſſociate with it the ideas of turbulence and fanaticiſm, with which it certainly has no natural connection. Their coincidence with ſome of thoſe oppreſſed and infatuated people, in denying baptiſm to infants, is acknowledged by the Baptiſts: but they diſavow the practice which the appellation of Anabaptiſts implies; and their doctrines ſeem referable to a more ancient and reſpectable origin. They appear ſupported by hiſtory, in conſidering themſelves as the deſcendants of the Waldenſes, who were ſo grievouſly oppreſſed and perſecuted by the deſpotic heads of the Roman hierarchy; and they profeſs an equal averſion to all principles of rebellion on one hand, and to all ſuggeſtions of fanaticiſm on the other.

The denomination of Mennonites, by which they are diſtinguiſhed in Holland, they derive from Menno, the famous man who latterly gave conſiſtence and ſtability to their ſect.

ANABASII, in antiquity, were couriers who were ſent on horſeback, or in chariots, with diſpatches of importance.

ANABASIS, in medicine, implies the riſe and progreſs of a diſorder, from its loweſt to its higheſt pitch. In grammar it denotes to aſcend higher.

ANABASIUS, in botany, ſignifies the uſnea, or hairy moſs-tree, for which it is a trivial name.

ANABATA, in eccleſiaſtical hiſtory, denotes the ſhoulder covering of the ſacerdotal habit; uſually put on when an extraordinary occurrence required the prieſt to notify any thing in the ſuperlative degree, whether good or evil.

ANABATHRA, in ancient writers, denote a kind of ſteps or ladder, whereby to aſcend ſome eminence. In this ſenſe we read of the anabathra of theatres, pulpits, &c. Anabathra appears to have been ſometimes alſo applied to ranges of ſeats riſing gradually over each other.

Anabathra is more particularly applied to a kind of ſtone blocks raiſed by the highway ſides, to aſſiſt travellers in mounting or alighting, before the uſe of ſtirrups was invented.

ANABIBAZON, in aſtronomy, ſignifies the dragon's tail.

ANABLATUM, in botany, a ſynonyme of the dentaria, or tooth-wort.

ANABLEPS, in ichthyology, the trivial name of a ſpecies of cobitis.

ANABOLÆUM, or **Anabole**, in antiquity, a kind of great or upper coat, worn over the tunica.

ANABOLEUS, in antiquity, an appellation given to grooms of the ſtable, or equerries, who aſſiſted their maſters in mounting or diſmounting their horſes. As the ancients had no ſtirrups, they either jumped upon his back, or were aided in mounting by anabolei.

ANABROSIS, in ſurgery, denotes the iſſuing of blood through a hole in a vein worn by corroſion. In modern practice it is termed diabroſis.

ANACA, in ornithology, a name given by the natives of South America, to the Brazilian parroquet.

ANACANDAIA, in amphibiology, ſignifies a Ceylonic term for the bubalinus, or cattle ſerpent, well known to the Dutch in the iſland of Ceylon.

ANACALYPTERIA, according to Suidas, were preſents made to the bride by her huſband's relations and friends when ſhe firſt uncovered her face and ſhowed herſelf to men.

Theſe preſents were alſo called επαυλια: for, among the Greeks, virgins before marriage were under ſtrict confinement, being rarely permitted to appear in public, or converſe with the other ſex; and when allowed that liberty, wore a veil over their faces, termed Καλυπτρον, or Καλυπτρα, which was not left off in the preſence of men till the third day after marriage; whence, according to Heſychius, this day was alſo called anacalypterion.

ANACAMPSEROS, in botany, a ſynonyme of the portulaca and ſeveral other plants.

ANACAMPTERIA, in eccleſiaſtical antiquity, a kind of little edifices, adjacent to churches, deſigned for the entertainment of ſtrangers and poor perſons.

ANACAMPTIC, a name applied by the ancients to that part of optics which treats of reflection, being the ſame with what is now called **Catoptrics**.

ANACARDIUM, or **Cashew-nut Tree**, a genus of the monogynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 12th order, Holoraceæ. For the characters ſee Syſtem of **Botany**.

Only one ſpecies is as yet known to the botaniſts, viz. the occidentale. It grows naturally in the Weſt Indies, and arrives at the height of 20 feet in thoſe places of which it is a native, but cannot be preſerved in Britain without the greateſt difficulty. The fruit of this tree is as large as an orange; and is full of an acid juice, which is frequently made uſe of in making punch. To the apex of this fruit grows a nut, of the ſize and ſhape of a hare's kidney, but much larger at the end which is next the fruit than at the other. The ſhell is very hard; and the kernel, which is ſweet and pleaſant, is covered with a thin film. Between this and the ſhell is lodged a thick, blackiſh, inflammable liquor, of ſuch a cauſtic nature in the freſh nuts, that if the lips chance to touch it, bliſters will immediately follow. The kernels are eaten raw, roaſted, or pickled. The milky juice of this tree will ſtain linen of a good black, which cannot be waſhed out.

ANACATHARSIS, among phyſicians, denotes a purgation by ſpitting, in contradiſtinction to catharſis, a purging downwards.

In divinity this term denotes, a ſatisfactory explication of ſome dark ſentence of Scripture by analogy only.

ANACATHARTIC, in pharmacy, ſignifies a vomit.

ANACEPHALÆOSIS, in rhetoric, the ſame with recapitulation.

ANACHARSIS, in mythology, a famous Scythian philoſopher, converſed with Solon, and lived an auſtere life. Upon his return from his travels through Greece, he attempted to change the ancient cuſtoms of Scythia, and to eſtabliſh thoſe of Greece; which proved fatal to him. The king ſhot him dead in a wood with an arrow. A great many ſtatues were erected to him after his death. He is ſaid to have invented tinder, the anchor, and the potter's wheel; but the latter is mentioned by Homer, who lived long before him.

ANACHIS, in mythology, the name given by the ancient Egyptians to one of the deities that were ſuppoſed to take upon them the care of every mortal at his birth. 1. Anachis, or Neceſſity; 2. Dynamis, or Power; 3. Tyche, or Fortune; 4. Eros, or Charity.

ANACHORET, in church hiſtory, denotes a hermit, or ſolitary monk, who retires from the ſociety of mankind into ſome deſart, with a view to avoid the temptations of the world, and to be more at leiſure for meditation and prayer. Such were Paul, Anthony, and Hilarion, the firſt founders of monaſtic life in Egypt and Paleſtine.

Anachorets, among the Greeks, conſiſt principally of monks, who retire to caves or cells, with the leave of the abbot, and an allowance from the monaſtery; never appearing again in the monaſtery, unleſs on ſolemn occaſions.

ANACHRONISM, in matters of literature, an error with reſpect to chronology, whereby an event is placed earlier than it really happened. The word is compounded of *ανα*, *higher*, and *χρονος*, *time*. Such is that of Virgil, who placed Dido in Africa at the time of Æneas, though in reality ſhe did not come there till 300 years after the taking of Troy. An error on the other ſide, whereby a fact is placed later and lower than it ſhould be, is called a *parachroniſm*.

ANACLASTIC **Glasses**, a kind of ſonorous phials, or glaſſes, chiefly made in Germany, which have the property of being flexible; and emitting a vehement noiſe by the human breath. They are alſo called *vexing glaſſes* by the Germans, *vexier glaſer*, on account of the fright and diſturbance they occaſion by their reſilition.

The anaclaſtic glaſſes are a low kind of phials with flat bellies, reſembling inverted funnels, whoſe bottoms are very thin, ſcarce ſurpaſſing the thickneſs of an onion peel: this bottom is not quite flat, but a little convex. But upon applying the mouth to the orifice, and gently inſpiring, or as it were ſucking out the air, the bottom gives way with a prodigious crack, and of convex becomes concave. On the contrary, upon exſpiring or breathing gently into the orifice of the ſame glaſs, the bottom with no leſs noiſe bounds back to its former place, and becomes gibbous as before.

The anaclaſtic glaſſes firſt taken notice of were in the caſtle of Goldbach; where one of the academiſts *Naturæ Curioſorum*, having ſeen and made experiments on them, publiſhed a piece expreſs on their hiſtory and phenomena. They are all made of a fine white glaſs. It is to be obſerved in theſe, 1. That if the bottom be concave at the time of inſpiration, it will burſt; and the like will happen if it be convex at the time of exſpiration.

2. A ſtrong breath will have the ſame effect even under the contrary circumſtances.

ANACLASTICS, that part of optics which conſiders the refraction of light, and is commonly called *Dioptrics*.

ANACLATICS, or ANACLASTICS, that part of optics which treats of refracted light. It is a very obſolete term.

ANACLETERIA, in antiquity, a ſolemn feſtival celebrated by the ancients, when their kings or princes came of age, and aſſumed the reins of government. It is ſo called, becauſe proclamation being made of this event to the people, they went to ſalute their prince during the anacleteria, and to congratulate him on his new dignity.

ANACLETICUM, in the ancient art of war, was a particular blaſt of the trumpet, by which the fearful and flying ſoldiers were rallied, and re-called to the combat.

ANACLINOPALE, Ανακλινοπαλη, in antiquity, a kind of wreſtling, wherein the champions threw themſelves voluntarily on the ground, and continued the combat by pinching, ſcratching, biting, and other methods of offence. The *Anaclinopale* was contradiſtinguiſhed from the *Orthopale*, wherein the champions ſtood erect. In the *Anaclinopale*, the weaker combatants ſometimes gained the victory.

ANACLINTERIA, in antiquity, a kind of pillows on the dining bed, whereon the gueſts uſed to lean. The ancient tricliniary beds had four pillows, one at the head, another at the feet, a third at the back, and a fourth at the breaſt. That on which the head lay was properly called by the Greeks *ανακλιντηριον*, or *ανακλιντρον*; by the Romans *fulcrum*, ſometimes *pluteus*.

ANACLYPHA, in antiquity, denotes thoſe veſſels adorned with raiſed ſculpture, or baſſo relievo.

ANACOLLEMA, a compoſition of aſtringent powders, applied by the ancients to the head, to prevent defluctions on the eyes.

ANACONDO, in natural hiſtory, is a name given in the Iſle of Ceylon to a very large and terrible rattle-ſnake, which often devours the unfortunate traveller alive; yet, what is moſt extraordinary, it is accounted excellent and delicious food.

ANACREONTIC VERSE, in ancient poetry, a kind of verſe ſo called from its being much uſed by the poet Anacreon. It conſiſts of three feet and an half, uſually ſpondees and iambuſes, and ſometimes anapeſts: ſuch is that of Horace,

Lydia, dic per omnes.

No one has given a juſter character of the writings of Anacreon than the God of Love, as taught to ſpeak by Mr. Cowley:

All thy verſe is ſofter far
Than the downy feathers are,
Of my wings, or of my arrows,
Of my mother's doves and ſparrows:
Graceful, cleanly, ſmooth, or round,
All with Venus' girdle bound.

ANACRISIS, among the ancient Greeks, was uſed for a kind of trial or examination, which the archons, or chief magiſtrates, of Athens, were to undergo before their admiſſion into that office. The *anacriſis* ſtands diſtinguiſhed from the *docimaſia*, which was a ſecond examination, in the forum. The anacriſis was performed in the ſenate-houſe.

ANACRISIS, among civilians, an inveſtigation of truth, interrogation of witneſſes, and inquiry made into any fact.

ANACROSIS, in antiquity, denotes a part of the Pythian ſong, wherein the combat of Apollo and Python are deſcribed. The anacroſis was the firſt part, and contained the preparation to the fight.

ANACYCLUS, in botany, a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and, in the natural method, ranking under the 49th order, compoſitæ-diſcoides. The characters are: The calyx is hemiſpheric and imbricated. The carolla is radiated. The ſtamina conſiſt of five very ſhort capillary filaments, the anthera cylindric and tubular. The piſtillum has an oval germen; a filiform ſtylus; a bifid ſtigma in the hermaphrodites, two ſlender reflected ſtigmata in the females: there is no pericarpium, but the calyx unchanged. The ſeeds are ſolitary, with membranous wings, the receptaculum is chaffy.

ANADAVADÆA, in ornithology, a barbarous name of a ſpecies of alauda.

ANADEMA, among the ancients, denotes an ornament of the head, wherewith victors at the ſacred games had their temples bound.

ANADIPLOSIS, in rhetoric and poetry, ſignifies a repitition of the laſt word of a line, or clauſe of a ſentence, in the beginning of the next: Thus,

Pierides, vos hæc facietis maxima Gallo:
Gallo cujus amor, &c.
Et matutinis accredula vocibus inſtat,
Vocibus inſtat, & aſſiduas jacit ore querelas.

ANADIPLOSIS, in medicine, denotes a return of the paroxiſm,

ANADROMOUS, among ichthyologiſts, a name given to ſuch fiſhes as go from the ſea to the freſh waters at ſtated ſeaſons, and return back again; ſuch as the ſalmon, &c.

ANADUOMENE VENUS, in the Grecian mythology, anſwered to the Sea-Venus in the Roman, and was the appellation given to one of the chief deities of the ſea. The moſt celebrated picture in all antiquity was that of this goddeſs by Apelles; and the famous Venus of Medici is a Sea-Venus.

ANADYSIS, in ancient divinity, denotes the emerſion, or riſing up in baptiſm, contradiſtinguiſhed from immerſion, a going down.

ANÆDEIA, in antiquity, a denomination given to a ſilver ſtool placed in the Areopagus, on which the defendant, or perſon accuſed, was ſeated for examination. The word is Greek, *Αν-εδεια*, which imports, imprudence. The plaintiff, or accuſer, was placed on an oppoſite ſtool called *hybris*, or injury; here he propoſed three queſtions to the party accuſed, to which poſitive anſwers were to be given. The firſt, Are you guilty of this act? The ſecond, How did you commit it? The third, Who were your accomplices?

ANÆSTHESIA, ſignifies a privation of the ſenſes.

ANAGALLIS, PIMPERNEL, a genus of the monogynia order, belonging to the pentandria claſs of plants; and, in the natural method, ranking under the 20th order, Rotaceæ. For the characters, ſee Syſtem of BOTANY. There are four ſpecies of this plant, viz. 1. The arvenſis, or common pimpernel, with a red flower. 2. The fæmina, with a blue flower. 3. The monelli, or narrow-leaved pimpernel. 4. The latifolia, or Spaniſh pimpernel. The firſt ſort is very common in corn fields, and other cultivated places in Britain. The ſecond is ſometimes found wild in the fields, but is not ſo common as the firſt. The third is a beautiful ſmall perennial plant, and produces numbers of fine blue flowers. The fourth is a native of Spain, and likewiſe produces blue flowers.

ANAGALLIS AQUATICA, in botany, a trivial name for the well-known water herb, brook-lime.

ANAGNOSTA, or ANAGNOSTES, in antiquity, a kind of literary ſervant, retained in the families of perſons of diſtinction, whoſe chief buſineſs was to read to them during meals, or at any other time when they were at leiſure. Cornelius Nepos relates of Atticus, that he had always an agnoſtes at his meals. He never ſupped without reading; ſo that the minds of his gueſts were no leſs agreeably entertained than their appetites. The ſame cuſtom, Eginhard obſerves, was kept up by Charlemagne, who at table had the hiſtories and acts of ancient kings read to him. This cuſtom ſeems to have been a relic of that of the ancient Greeks, who had the praiſes of great men and heroes ſung to them while at table. The ancient monks and clergy kept up the like uſage, as we are informed by St. Auguſtin.

ANAGOGIA, in mythology, were ſacrifices to Venus; the ritual of which was obſerved at Eryx in Sicily.

ANAGOGICAL, ſignifies myſterious, tranſporting; and is uſed to expreſs whatever elevates the mind, not only to the knowledge of divine things here, but in the next life. This word is ſeldom uſed, but with regard to the different ſenſes of Scripture. The anagogical ſenſe is, when the ſacred text is explained with a regard to eternal life, the point which Chriſtians ſhould have in view: for example, the reſt of the ſabbath, in the anagogical ſenſe, ſignifies the repoſe of everlaſting happineſs.

ANAGOGY, or ANAGOGE, among eccleſiaſtical writers, the elevation of the mind to things celeſtial and eternal. It is particularly uſed, where words, in their natural or primary meaning, denote ſomething ſenſible, but have a further view to ſomething ſpiritual or inviſible.

ANANOGY, in a more particular ſenſe, denotes the application of the types and allegories of the Old Teſtament to ſubjects of the New; thus called, becauſe, the veil being here drawn, what before was hidden, is expoſed to open ſight.

ANAGRAM (from the Greek *ανα*, *backwards*, and *γραμμα*, *letter*) in matters of literature, a tranſpoſition of the letters of ſome name, whereby a new word is formed, either to the advantage or diſadvantage of the perſon or thing to which the name belongs. Thus, the anagram of Galenus is *angelus*; that of Logica, *caligo*; that of Alſtedius, *ſedulitas*; that of Loraine is *alerion*, on which account it was that the family of Loraine took *alerions* for their armoury.

Calvin, in the title of his *Inſtitutions*, printed at Straſburg in 1539, calls himſelf *Alcuinus*, which is the anagram of Calvinus, and the name of an eminently learned perſon in the time of Charlemagne, who contributed greatly to the reſtoration of learning in that age.

Thoſe who adhere ſtrictly to the definition of an anagram, take no other liberty than that of omitting or retaining the letter H, at pleaſure; whereas others make no ſcruple to uſe E for Æ, V for W, S for Z, and C for K; and *vice verſa*.

Anagrams are ſometimes made out of ſeveral words: ſuch is that on the queſtion put by Pilate to Our Saviour, *Quid eſt veritas?* whereof we have this admirable anagram, viz. *Eſt vir qui adeſt.*

The Cabbaliſts among the Jews are profeſſed anagrammatiſts; the third part of their art, which they call *themuru*, i. e. "changing," being nothing but the art of making anagrams, or of finding hidden and myſtical meanings in names; which they do by changing, tranſpoſing, and differently combining, the letters of thoſe names.

ANAGRAMMATIST, a maker or compoſer of anagrams.

ANAGROS, in commerce, a meaſure for grain uſed in ſome cities of Spain, particularly at Seville; 46 anagros make about 10½ quarters of London.

ANAGYRIS, STINKING BEAN-TREFOIL, a genus of the monogynia order, belonging to the decandria claſs of plants; and, in the natural method, ranking under the 32d order, papilionaceæ. For the characters, ſee Syſtem of BOTANY.

There is but one ſpecies of this plant, namely, the fetida, which grows naturally in the ſouthern parts of Europe. It is a ſhrub which uſually riſes to the height of eight or ten feet, and produces its flowers in April or May. Theſe are of a bright yellow colour, growing in ſpikes, ſomewhat like the laburnum.

ANAGYRIS, or **ANAGYRUS**, the name of a place in Attica, of the tribe Erechtheis, where a fetid plant, called anagyris, probably the ſame with the foregoing, grew in great plenty, (Dioſcorides, Pliny, Stephanus;) and the more it was handled, the ſtronger it ſmelled: hence *commovere anagyrin* (or *anagyrum*) is to bring a misfortune on one's ſelf, (Ariſtophanes.)

ANAITIS, in mythology, a goddeſs of the Armenians: at the rites of the ſacrifice to this infernal deity, the virgins of all ranks proſtituted themſelves by the ſtrict injunction of their parents! no rank or claſs were exempt from the obſervance of this diabolical cuſtom.

ANAK, in Scripture, the father of the Anakims, was the ſon of Arba, who gave his name to Kirjath-arba, or Hebron, Joſh. xiv. 15. Anak had three ſons, Sheſhai, Ahiman, and Talmai, (chap. xv. 14. and Numb. xiii. 22.) who, as well as their father, were giants, and who with their poſterity, all terrible for their fierceneſs and extraordinary ſtature, were called the Anakims; in compariſon of whom the Hebrews, who were ſent to view the land of Canaan, reported that they were but as graſshoppers. Numb. xiii. *ult.* Caleb, aſſiſted by the tribe of Judah, took Kirjath-arba, and deſtroyed the Anakims, (Judges i. 20. and Joſh. xv. 14.) in the year of the world 2559.

ANALECTA, or **ANALECTES**, in antiquity, a ſervant whoſe employment it was to gather up the off-falls of tables.

ANALECTA, *Analects*, in a literary ſenſe, is uſed to denote a collection of ſmall pieces; as eſſays, remarks, &c.

ANALEMMA, in geometry, a projection of the ſphere on the plane of the meridian, orthographically made by ſtraight lines and ellipſes, the eye being ſuppoſed at an infinite diſtance, and in the eaſt or weſt points of the horizon.

ANALEMMA, denotes likewiſe an inſtrument of braſs or wood, upon which this kind of projection is drawn, with an horizon and curſor fitted to it, wherein the ſolſtitial colure, and all circles parallel to it, will be concentric circles; all circles oblique to the eye will be ellipſes; and all circles whoſe planes paſs through the eye will be right lines. The uſe of this inſtrument is to ſhow the common aſtronomical problems; which it will do, though not very exactly, unleſs it be very large.

ANALEPSIS, the augmentation or nutrition of an emaciated body.

ANALEPTICS, reſtorative or nouriſhing medicines.

ANALOGY, in philoſophy, a certain relation and agreement between two or more things, which in other reſpects are entirely different.

There is always an analogy between beings that have ſome conformity or reſemblance to one another; for example, between animals and plants; but the analogy is ſtill ſtronger between two different ſpecies of certain animals.

Analogy enters much into all our reaſoning, and ſerves to explain and illuſtrate. A great part of our philoſophy has no other foundation than analogy.

It is natural to mankind to judge of things leſs known, by ſome ſimilitude, real or imaginary, between them and things more familiar or better known. And if the things compared have really a great ſimilitude in their nature, when there is reaſon to think that they are ſubject to the ſame laws, there may be a conſiderable degree of probability in concluſions drawn from anology.

Thus we may obſerve a ſimilitude between this earth which we inhabit, and the other planets, Saturn, Jupiter, Mars, Venus, and Mercury. They all revolve round the ſun, as the earth does, although at different diſtances, and at different periods. They borrow all their light from the ſun, as the earth does. Several of them are known to revolve round their axis like the earth, and, by that means, muſt have a like ſucceſſion of day and night. Some of them have moons, that ſerve to give them light in the abſence of the ſun, as our moon does to us. They are all, in their motions, ſubject to the ſame law of gravitation, as the earth is. From all this ſimilitude, it is not unreaſonable to think, that thoſe planets may, like our earth, be the habitation of various orders of living creatures. There is ſome probability in this concluſion from analogy.

But it ought to be obſerved, that, as this kind of reaſoning can afford only probable evidence at beſt; ſo unleſs great caution be uſed, we are apt to be led into error by it. To give an inſtance of this: anatomiſts, in ancient ages, ſeldom diſſected human bodies; but very often the bodies of thoſe quadrupeds whoſe internal ſtructure was thought to approach neareſt to that of the human body. Modern anatomiſts have diſcovered many miſtakes the ancients were led into, by their conceiving a greater ſimilitude between the ſtructure of men and of ſome beaſts than there is in reality.

Analogical reaſoning may be of excellent uſe in anſwering objections againſt truths which have other evidence. It may alſo give a greater or leſs degree of probability in caſes where we can find no other evidence. But in all arguments drawn from analogy the greater the diſparity between the things compared, the leſs convincive are the concluſions deduced from them.

There is no ſubject in which men have always been ſo prone to form their notions by analogies of this kind, as in what relates to the mind. We form an early acquaintance with material things by means of our ſenſes, and are bred up in a conſtant familiarity with them. Hence we are apt to meaſure all things by them; and to aſcribe to things moſt remote from matter the qualities that belong to material things.

To illuſtrate more fully that analogical reaſoning from a ſuppoſed ſimilitude of mind to body, which appears to be the moſt fruitful ſource of error with regard to the operations of our minds, the following inſtance may be given. When a man is urged by contrary motives, thoſe on one hand inciting him to do ſome action, thoſe on the other to forbear it; he deliberates about it, and at laſt reſolves to do it, or not to do it. The contrary motives are here compared to the weights in the oppoſite ſcales of a balance; and there is not perhaps any inſtance that can be named of a more ſtriking analogy between body and mind. Hence the phraſes of weighing motives, of deliberating upon actions, are common to all languages.

From this analogy, ſome philoſophers draw very important concluſions. They ſay, that, as the balance cannot incline to one ſide more than the other, when the oppoſite weights are equal; ſo a man cannot poſſibly determine himſelf if the motives on both hands are equal; and as the balance muſt neceſſarily turn to that ſide which has moſt weight, ſo the man muſt neceſſarily be determined to that hand where the motive is ſtrongeſt. And on this foundation ſome of the ſchoolmen maintained, that if a hungry aſs were placed between two bundles of hay equally inviting, the beaſt muſt ſtand ſtill and ſtarve to death, being unable to turn to either, becauſe there are equal motives to both. This is an inſtance of that anological reaſoning, which, it is conceived, ought never to be truſted; for the analogy between a balance and a man deliberating, though one of the ſtrongeſt that can be found between matter and mind, is too weak to ſupport any argument.

The derivation of the word Analogy indicates, as profeſſor Caſtillon of Berlin obſerves, a reſemblance diſcernable by reaſon. This is confirmed by the ſenſe in which the term is uſed in geometry, where it ſignifies an equality of ratios. In explaining this ſubject, it is obſerved, there may be a reſemblance between ſenſations and a reſemblance between perceptions: the former is called *phyſical reſemblance*, becauſe it acts upon the phyſical or ſenſitive faculty; the latter *moral reſemblance*, becauſe it affects the moral or rational faculty of man.

Every reſemblance may be reduced to an equality in ſenſations or perceptions; but this ſuppoſes ſome equality in their cauſes: we ſay *ſome equality*, becauſe the diſpoſition of the organs, or of the ſoul, muſt neceſſarily affect the ſenſations or perceptions; but this can influence only their degree, and not their nature.

The character of one perſon reſembles that of another only when they both ſpeak and act ſo as to excite equal perceptions, or to ſpeak more ſtrictly, the ſame perception; when they both diſplay vivacity or indifference, anger or meekneſs, on the ſame occaſions, and both excite in the ſoul of the obſerver identical perceptions, or rather the ſame perception of vivacity or indifference, of anger or meekneſs.

Theſe identical perceptions, the degree of which will depend much on the diſpoſition of the obſerver's mind, muſt have identical cauſes, or, in other words, the ſame cauſe; which is the vivacity or indifference, the anger or meekneſs, diſplayed by each of theſe characters.

Every phyſical reſemblance may therefore be reduced to one or more equalities; and every moral reſemblance to one or more identities. Wherever there is moral reſemblance there is analogy. Analogy may therefore be reduced to identity, and always ſuppoſes compariſon.

Two objects are ſaid to have an analogy to each other, or are *analogous*, when ſome identity is diſcovered upon comparing them. An *analogical concluſion*, is a concluſion deduced from ſome identity.

The principles of analogy are a compariſon of two objects; and one or more identities reſulting from their being thus compared. The characters of analogy are; that two objects be compared; that there be one or more identities between theſe objects; and that this is diſcernible only be reaſon or intellect.

Phyſical reſemblance is to the ſenſes what analogy is to the underſtanding. The former, when perfect, becomes equality; but the latter, identity. Reſemblance and analogy are the foundations both of probability and of certainty. When we are ſatisfied that the reſemblance or the analogy is complete, we ſtop at probability; which becomes certainty when we are, or think we are, aſſured that the reſemblance or the analogy is perfect.

In reaſoning by analogy, we ſhould be careful not to confound it with reſemblance; and alſo not to deduce from the identity or identities, on which the analogy is founded, a concluſion, which has either no relation, or only a partial relation, to theſe identities.

The principal uſe of analogy in the inveſtigation of phyſical and moral truth, may be reduced to the four following maxims: 1. By means of our ſenſes to improve, firſt our own judgment, and afterwards that of others, with reſpect to intellectual ſubjects. 2. To deduce a general from a particular truth. Having diſcovered and proved the truth of a propoſtion with reſpect to any particular object, examine whether this truth flows from a quality peculiar to this ſingle object, or common to ſeveral objects. In the latter caſe all theſe objects may be comprehended under one general idea, founded on their common quality. Subſtitute this general idea inſtead of the particular object, and the propoſition will become general, without ceaſing to be true; becauſe whatever evidently and ſolely reſults from the identity, on which an analogy is founded, muſt neceſſarily be true with reſpect to all thoſe objects in which the analogy is the ſame. 3. To prove the truth or falſehood of propoſitions which cannot be otherwiſe demonſtrated. 4. To diſcover new truths in both natural and moral philoſophy.

ANALOGY, among grammarians, is the correſpondence which a word or phraſe bears to the genius and received forms of any language.

ANALYSIS, in a general ſenſe, implies the reſolution of ſomething compounded into its original and conſtituent parts. The word is Greek, and derived from ἀναλυω, to reſolve.

ANALYSIS, in mathematics, is properly the method of reſolving problems by means of algebraical equations; whence we often find that theſe two words, *analyſis* and *algebra*, are uſed as ſynonymous.

Analyſis, under its preſent improvements, muſt be allowed the apex or height of all human learning: it is this method which furniſhes us with the moſt perfect examples of the art of reaſoning; gives the mind an uncommon readineſs at deducing and diſcovering, from a few data, things unknown; and, by uſing ſigns for ideas, preſents things to the imagination, which otherwiſe ſeemed out of its ſphere: by this, geometrical demonſtrations may be greatly abridged, and a long ſeries of argumentations, wherein the mind cannot without the utmoſt effort and attention diſcover the connection of ideas, are hereby converted into ſenſible ſigns, and the ſeveral operations required therein effected by the combination of thoſe ſigns. But, what is more extraordinary, by means of this art, a number of truths are frequently expreſſed by a ſingle line, which in the common way of explaining and demonſtrating things would fill whole volumes. Thus, by mere contemplation of one ſingle line, whole ſciences may be ſometimes learnt in a few minutes time, which otherwiſe could ſcarce be attained in many years.

ANALYSIS is divided, with regard to its object, into that of *finites* and *infinites*.

ANALYSIS *of Finite Quantities*, is what we otherwiſe call ſpecious arithmetic or algebra.

ANALYSIS *of Infinites*, called alſo the *New Analyſis*, is particularly uſed for the method of fluxions, or the different calculus.

ANALYSIS, in logic, ſignifies the method of tracing things backward to their ſource, and of reſolving knowledge into its original principles. This is alſo called the method of *reſolution*; and ſtands oppoſed to the ſynthetic method, or that of *compoſition*. The art of logical analyſis conſiſts principally in combining our perceptions, claſſing them together with addreſs, and contriving proper expreſſions for conveying our thoughts, and repreſenting their ſeveral diviſions, claſſes, and relations.

ANALYSIS, in rhetoric, is that which examines the connections, tropes, figures, and the like, inquiring into the propoſition, diviſion, paſſions, arguments, and other apparatus of rhetoric.

ANALYSIS, in chemiſtry, implies the decompounding of a mixed body, or the ſeparation of the principles and conſtituent parts of a compounded ſubſtance.

To analyze bodies, or reſolve them into their component parts, is indeed the chief object of the art of chemiſtry. Chemiſtry furniſhes ſeveral means for the decompoſition of bodies, which are all founded on the differences of the properties belonging to the different principles of which the body to be analyzed is compoſed. If, for example, a body be compoſed of ſeveral principles, ſome of which have a great, and others a moderate degree of volatility; and, laſtly, others are fixed, its moſt volatile parts may be firſt ſeparated by a gradual heat in diſtilling veſſels; and then the parts which are next in volatility will paſs over in diſtillation; and laſtly, thoſe parts which are fixed, and capable of reſiſting the action of fire, will remain at the bottom of the veſſel.

ANALYSIS, in lectures, is a kind of ſyllabus, or table of the principal heads or articles of a continued diſcourſe, diſpoſed in their natural order and dependency. Analyſes are more ſcientifical than alphabetical indexes; but they are leſs uſed, as being more intricate.

ANALYSIS is frequently uſed for a brief, but methodical, illuſtration of the principles of a ſcience; in which ſenſe it is nearly ſynonymous with what we otherwiſe call a *ſynopſis*.

ANALYTIC, or ANALYTICAL, ſomething that belongs to, or partakes of, the nature of analyſis.

The analytic method ſtands oppoſed to the ſynthetic. In natural philoſophy, as in mathematics, the inveſtigation of difficult things by the analytic method ought to precede the method of compoſition. This analyſis conſiſts in making of experiments and obſervations, and in drawing general concluſions therefrom by induction; and admitting of no objections againſt the concluſions, but ſuch as are drawn from experiments, or other certain truths: and although reaſoning from experiments and obſervations by induction be no demonſtration of general concluſions, yet it is the beſt method which the nature of things will admit of; and may be eſteemed ſo much the ſtronger, as the induction is more general; and, if no exception occur from phenomena, the concluſion may be pronounced general.

By this way of analyſis, we may proceed from compounds to their ingredients; from motions to the forces producing them; and in general from effects to their cauſes, and from particular cauſes to more general ones, until we arrive at thoſe which are the moſt general. This is the analytic method, according to the illuſtrious Sir Iſaac Newton.

The ſynthetic method conſiſts in aſſuming the cauſes diſcovered and received as principals: and by them explaining the phenomena proceeding from them, and proving the explanation.

ANALYTICS, *Analytica*, the ſcience and uſe of analyſis. The great advantage of the modern mathematics above the ancient is in point of analytics.

Pappus, in the preface to his ſeventh book of Mathematical Collections, enumerates the authors on the ancient analytics; being Euclid, in his *Data* and *Poriſmata*; Apollonius, *de Sectione Rationis*, and in his *Conics*; Ariſtæus, *de Locis Solidis*; and Eratoſthenes, *de Mediis Proportionalibus*. But the ancient analytics were very different from the modern analytics, to which principally belong algebra and fluxions.

ANAMELECH, in mythology, an idol of the Sepharvaites, who are ſaid in Scripture to have burned their children in honour of Adrammelech and Anamelech. Theſe idols probably ſignified the ſun and moon. Some of the rabbins repreſent Anamelech under the figure of a mule, others under that of a quail or pheaſant.

ANAMIM, in Scripture, the ſecond ſon of Mizraim (Gen. x. 13.) who peopled the Mareotis; or the Pentapolis of Cyrene, according to the paraphraſt of Jeruſalem. Bochart is of opinion that theſe Anamims were the people that dwelt in the parts adjacent to the temple of Jupiter Ammon, and in the Naſamonitis. Calmet thinks the Amanians and Garamantes to be deſcended from Anamim.

ANAMORPHOSIS, in perſpective drawings, is a deformed or diſtorted portrait or figure, generally confuſed and unintelligible to the common unaſſiſted view; but when ſeen at a certain diſtance and height, or as reflected from a plain or curved mirror, will appear regular and in right proportion.

ANAMNESTICS, among phyſicians, imply the former habits of body of a patient. It alſo denotes thoſe medicines which are neceſſary to ſtrengthen the animal ſyſtem, particularly the memory.

ANANAS, in botany, the trivial name of a ſpecies of bromelia.

ANANCITIS, in antiquity, a kind of figured ſtone, otherwiſe called *ſynochitis*, celebrated for its magical virtue of raiſing the ſhadows of the infernal gods.

ANANIAS, in holy writ, a Sadducee, high-prieſt of the Jews, who put to death St. James the couſin of our Lord, and was depoſed by Agrippa.

ANANISABTA, or ANANISAPTA, a magical word frequently found inſcribed on coins and other amulets, ſuppoſed to have a virtue of preſerving the wearer from the plague.

ANANTA PADMANABA URATAM, in the Eaſtern code of religion, implies a ſolemn feſtival of the Indian Bramins.

It is celebrated annually on the 14th day after the new moon of Auguſt, in order to obtain health in this life, and happineſs in the next.

ANAPÆST, in ancient poetry, a foot conſiſting of two ſhort ſyllables and one long: ſuch is the word ſcŏpŭlōs. It is juſt the reverſe of the dactyl.

ANAPÆSTIC VERSES, thoſe conſiſting wholly or chiefly of anapeſts.

ANAPHORA, in rhetoric, the repetion of the ſame word or words in the beginning of a ſentence or verſe. Thus Virgil:

Pan etiam Arcadia mecum ſe judice certet,
Pan etiam Arcadia dicat ſe judice victum.

ANAPHORA, among phyſicians, the throwing off purulent matter by the mouth.

ANAPHRODISIA, ſignifies impotence, or want of power to procreate.

ANAPLASIS, in ſurgery, ſignifies the replacing or ſetting a fractured bone.

ANAPHYSEMATA, in antiquity, implies the iſſuing forth of a religioniſt from his cell, or the miner from his ſubterranean employment.

ANAPLEROSIS, in ſurgery, denotes repletion, or whatever is wanting to be amply ſupplied.

ANAPLORETICS, in medicine, are ſuch remedies as promote the growth or granulation of the fleſh, in wounds, ulcers, &c. ſometimes called incarnatives.

ANARCHI, Αναρσχοι, in antiquity, a name given by the Athenians to four ſupernumerary days in their year, during which they had no magiſtrates.

The attic year was divided into ten parts, according to the number of tribes, to whom the precedency of the ſenate fell by turns. Each diviſion conſiſted of 35 days; what remained after the expiration of theſe, to make the lunar year complete, which according to their computation conſiſted of 354 days, were employed in the creation of magiſtrates, and called *αναρχοι ημεραι* and *αρχαιρεσιοι*.

ANARCHY, the want of government in a nation, where no ſupreme authority is lodged, either in the prince or other rulers; but the people live at large, and all things are in confuſion.

The word is derived from the Greek privative *α*, and *αρσχη*, command, principality. Anarchy is ſuppoſed to have reigned after the deluge, before the foundation of monarchies.

ANARCHY is frequently applied to certain troubleſome and diſorderly periods, even in governments otherwiſe regular. In England, the period between the death of Cromwell and king Charles's reſtoration, is commonly repreſented as an anarchy.

No modern nation is more ſubject to anarchies than Poland; where every interval between the death of one king, and the election of another, is a perfect picture of confuſion; inſomuch, that it is a proverb among that people, *Poland is governed by confuſion.*

The Jewiſh hiſtory preſents numerous inſtances of anarchies in that ſtate, uſually denoted by this phraſe, that *in thoſe days there was no king in Iſrael, but every man did that which was right in his own eyes*; which is a juſt picture of an anarchy.

ANARGYRUS, in church hiſtory, denotes a name given by the Greek Chriſtians to Coſmus and Damianus, whoſe feſtival is kept on the 1ſt of November.

In ancient law books it implies the ſtate of a perſon without money.

ANARRAPHE, in ſurgery, denotes a kind of ſuture or retraction of the upper eyelid, when relaxed and hanging over the eye.

ANARRHICAS, in ichthyology, a genus of fiſhes of the order of apodes. There is but one ſpecies of this genus, the anarrhicas lupus, or ſea-wolf; which ſeems to be confined to the northern parts of the globe. It is found in the Greenland ſeas, and in thoſe of Iceland and Norway, and ſometimes on the coaſts of Scotland and Yorkſhire; and, laſtly, in that part of the German ocean which waſhes the ſhores of Holland.

It is a ravenous fierce fiſh, and, when taken, faſtens on any thing within its reach; the fiſhermen, dreading its bite, endeavour as ſoon as poſſible to beat out its fore-teeth, and then kill it by ſtriking it behind the head.

It feeds almoſt entirely on cruſtaceous animals and ſhell-fiſh, which it grinds to pieces with its teeth, and ſwallows with the leſſer ſhells.

It does not appear they are diſſolved in the ſtomach, but are voided with the feces; for which purpoſe the aperture of the anus is wider than in other fiſh of the ſame ſize.

It is full of roe in February, March, and April, and ſpawns in May and June. They have been taken near Shetland ſeven feet long, and even more.

The head is a little flatted on the top: the noſe blunt; the noſtrils are very ſmall; the eyes ſmall, and placed near the end of the noſe.

The teeth are very remarkable, and finely adapted to its way of life. The fore-teeth are ſtrong, conical, diverging a little from each other, ſtand far out of the jaws, and are commonly ſix above and the ſame below; though ſometimes there are only five in each jaw: theſe are ſupported within-ſide by a row of leſſer teeth, which makes the number in the upper jaw 17 or 18, in the lower 11 or 12. The ſides of the under jaw are convex inwards, which greatly adds to their ſtrength, and at the ſame time allows room for the large muſcles with which the head of this fiſh is furniſhed. The *dentes molares*, or grinding teeth of the under jaw, are higher on the outer than the inner edges, which inclines their ſurfaces inward: they join to the canine teeth in that jaw, but in the upper are ſeparate from them. In the centre are two rows of flat ſtrong teeth, fixed on an oblong baſis upon the bones of the palate and noſe.

The body is long, and a little compreſſed ſidewiſe; the ſkin is ſmooth and ſlippery: it wants the lateral line. The pectoral fins conſiſt of 18 rays. The dorſal fin extends from the hind-part of the head almoſt to the tail; the rays in the freſh fiſh are not viſible. The anal fin extends as far as the dorſal fin. The tail is round at its end, and conſiſts of 13 rays. The ſides, back, and fins, are of a livid lead colour; the two firſt marked downwards with irregular obſcure duſky lines; theſe in different fiſh have different appearances.

ANARROPIA, among phyſicians, a tendency of the humours to the head or ſuperior parts.

ANARRPHINON, in botany, a trivial name for a ſpecies of flax.

ANAS, in ornithology, a genus of birds belonging to the order of anſeres. The beak of this genus is a little obtuſe, covered with an epidermis or ſkin, gibbous at the baſe, and broad at the apex: the tongue is obtuſe and fleſhy; the feet are webbed and fitted for ſwimming. The ſpecies are,

1. The cygnus, *ferus & manſuetus.*

The ferus, with a ſemi-cylindrical black bill, yellow wax, and a white body, is the whiſtling or wild ſwan, which is leſs than the tame or mute ſpecies, being about five feet in length. Theſe birds inhabit the northern hemiſphere from Iceland to Greece. They ſwarm, during ſummer, in the great lakes and marſhes of the Tartarian and Siberian deſerts; and reſort in great numbers to winter about the Caſpian and Euxine ſeas. Thoſe of the eaſtern parts of Siberia retire beyond Kamtſchatka, either to the coaſts of America, or to the iſles north of Japan.

In Carolina they are ſaid to be of two ſorts; the larger, called from its note the Trumpeter, arrive in great flocks to the freſh rivers in winter, and in February retire to the great lakes to breed: the leſſer are called Hoopers, and frequent moſtly the ſalt water. In Auguſt theſe birds loſe their feathers, and are not able to fly; when the natives of Iceland and Kamtſchatka hunt them with dogs, which catch them by the neck, and eaſily ſecure their prey.

The eggs are accounted good food; and the fleſh, eſpecially that of the young, is much eſteemed by inhabitants. The uſes of the feathers are manifeſt to every one; and the ſkins of the body are worn by the inhabitants; beſides which, that of the legs, taken off whole, is uſed for purſes, and appears not very unlike ſhagreen.

Wild ſwans, Linnæus ſays, frequently viſit Sweden after a thaw, and are caught with apples in which a hook is concealed.

The wild ſwan frequents our coaſts, in hard winters, in large flocks, but does not breed in Great Britain.

This ſpecies has ſeveral diſtinctions from the ſpecies which we call the tame ſwan. In Ruſſia this ſpecies more fitly claims the name, it being the kind moſt commonly tamed in that empire.

The whiſtling ſwan carries its neck quite erect, the other ſwims with it arched.

It is from this ſpecies alone that the ancients have given the fable of the ſwan being endued with the powers of melody.

Thus Horace calls Pindar *Dircæum Cygnum*; and in an ode ſuppoſes himſelf changed into a ſwan. Virgil ſpeaks of his poetical brethren in the ſame manner:

> *Vare, tuum nomen,*
> *Cantantes ſublime ferent ad ſidera cygni.*
>
> Eclog. ix.

When he ſpeaks of them figuratively, he aſcribes to them melody, or the power of muſic; but when he talks of them as birds, he lays aſide fiction, and, like a true naturaliſt, gives them their real note:

> *Dant ſonitum rauci per ſtagna loquacia cygni.*
>
> Æneid. lib. x. 50.

It was alſo a popular opinion among the ancients, that the ſwan foretold its own end. To explain this, we muſt conſider the twofold character of the poet, *vates* and *poeta*, which the fable of the tranſmigration continues to the bird; or they might be ſuppoſed to derive that faculty from Apollo, their patron deity, the god of prophecy and divination.

As to their being ſuppoſed to ſing more ſweetly at the approach of death, the cauſe is beautifully explained by Plato, who attributes that unuſual melody to the ſame ſort of ecſtaſy that good men are ſometimes ſaid to enjoy at that awful hour, foreſeeing the joys that are preparing for them on putting off mortality.

The manſuetus, or mute ſwan, is the largeſt of the Britiſh birds. It is diſtinguiſhed externally from the white ſwan; firſt, by its ſize, being much larger; ſecondly, by its bill, which in this is red, and the tip and ſides black, and the ſkin between the eyes and bill is of the ſame colour. Over the baſe of the upper mandible, projects a black callous knob: the whole plumage, in old birds, is white; in young ones, aſh-coloured till the ſecond year: the legs are duſky.

The ſwan is found wild in Ruſſia and Siberia, moſt plentiful in the laſt. It arrives later from the ſouth, and does not ſpread ſo far north. Thoſe about the ſouthern part of the Caſpian ſea are very large, and much eſteemed for the uſe of the table.

The ſwan is held in high veneration by the Mahometans. It is a very ſtrong bird, and ſometimes exceeding fierce: has not unfrequently been known to throw down and trample under feet youths of between fifteen or ſixteen years of age, and an old one to break the leg of a man with a ſtroke of the wings. It is ſaid to be very long-lived, and frequently to arrive at the hundredth year. They lay eight eggs, and ſit ſix weeks. They feed on both fiſh and herbage.

No bird, perhaps, makes ſo inelegant a figure out of the water, or has the command of ſuch beautiful attitudes on that element, as the ſwan; almoſt every poet has taken notice of it; but none with that juſtneſs of deſcription, and in ſo pictureſque a manner as our Milton:

> The ſwan, with arched neck
> Between her white wings mantling, proudly rows
> Her ſtate with oary feet.
>
> Par. Loſt, B. vii.

In former times, it was ſerved up at every great feaſt, when the elegance of the table was meaſured by the ſize and quantity of the good cheer.

Swans were formerly held in ſuch great eſteem in England, that, by an act of Edward IV. c. 6. "no one that poſſeſſed a freehold of leſs clear yearly value than five marks, was permitted to keep any, *other than the ſon of our ſovereign lord the king*." And by the eleventh of Henry VII. c. 17. the puniſhment for taking their eggs was impriſonment for a year and a day, and a fine, at the king's will. Though at preſent they are not ſo highly valued as a delicacy, yet great numbers are preſerved for their beauty.

2. The cygnoides, with a ſemi-cylindrical bill, gibbous wax, and tumid eye-brows. It is the ſwan-gooſe, of Ray, from Guinea. Theſe birds likewiſe inhabit Ruſſia, China, and are common at the Cape of Good Hope.

They are ſufficiently common in Britain, and readily mix with the common gooſe; the breeds uniting as freely, and continuing to produce as certainly, as if no ſuch mixture had taken place.

3. The tadorna, or ſheildrake, has a flat bill, a compreſſed forehead, a greeniſh black head, and the body is variegated with white. This ſpecies is found as far as Iceland to the north. It viſits Sweden and the Orkneys in the winter, and returns in ſpring. It is found in Aſia about the Caſpian Sea, and all the ſalt lakes of the Tartarian and Siberian deſarts, as well as in Kamtſchatka.

4. The ſpectabilis, has a compreſſed bill gibbous at the baſe, a black feathery carina, and a hoary head. It is the grey-headed duck of Edwards, and the king-duck of Pennant. This beautiful ſpecies is found at Hudſon's Bay, at Churchill River, and (though ſcarce) at York Fort; in winter it is met with as far ſouth as New York. It is pretty frequent in the north of Siberia and Kamtſchatka; it is found alſo on the coaſt of Norway, and has been killed in the Orkneys. It is common in Greenland; where the fleſh is accounted excellent, and the crude gibbous part of the bill a great delicacy. It produces a down equally valuable as the eider.

5. The fuſca, or velvet duck, is of a blackiſh colour, has a white ſpot behind the eyes, and a white line on the wings. The male of this ſpecies is diſtinguiſhed by a gibboſity at the baſe of the bill. It is the black duck of Ray, and is in length about 20 inches. This ſpecies frequents Hudſon's Bay in ſummer, where it breeds.

6. The nigra, or ſcoter, is totally black, and has a gibboſity at the baſe of the bill; the tail reſembles a wedge; the female is browniſh. It is the leſſer black diver of Ray, and meaſures in length 22 inches. Theſe birds are found on the northern coaſts of England, Scotland, and France, in the winter ſeaſon.

7. The anſer, *ferus et manſuetus*; or grey lag, and tame gooſe. The *grey lag*, or *wild gooſe*, is two feet nine inches in length, and five feet in extent. The bill is large and elevated; of a fleſh colour, tinged with yellow; the head and neck cinerous; breaſt and belly whitiſh, clouded with grey or aſh colour; back, grey; the legs of a fleſh colour. This ſpecies reſides in the fens the whole year; breeds there, and hatches about eight or nine young, which are often taken, eaſily tamed, and eſteemed moſt excellent meat, ſuperior to the domeſtic gooſe. Towards winter they collect in great flocks, but in all ſeaſons live and feed in the fens.

The *manſuetus*, is the grey lag in a ſtate of domeſtication, and from which it varies in colour, though much leſs ſo than either the mallard or cock, being ever more or leſs verging to grey; though in all caſes the whiteneſs of the vent, and upper tail coverts, is manifeſt. It is frequently found quite white, eſpecially the males: and doubts have ariſen, which of the two colours ſhould have the preference in point of eating.

The gooſe in general breeds only once in a year; but will frequently have two hatches in a ſeaſon, if well kept. The time of ſitting is about 30 days. They produce eggs ſufficient for three broods, if they are taken away in ſucceſſion. It is ſaid to be very long-lived, arriving at no leſs than 100 years.

8. The *bean gooſe* is two feet ſeven inches in length; in extent four feet eleven. The bill, which is the chief diſtinction between this and the former, is ſmall, much compreſſed near the end, whitiſh, and ſometimes pale red in the middle, and black at the baſe and nail: the head and neck are cinereous brown, tinged with ferruginous; breaſt and belly dirty white, clouded with cinereous; the back of a plain aſh colour; feet and legs of a ſaffron colour; claws black.

This ſpecies arrives in Lincolnſhire in autumn; and is called the *bean-gooſe*, from the likeneſs of the nail of the bill to a horſe-bean. They always light on corn-fields, and feed much on the green wheat. They never breed in the fens; but all diſappear in May. They retreat to the ſequeſtered wilds of the north of Europe; in their migration they fly a great height, cackling as they go.

9. The erythropus, or laughing-gooſe of Edwards, is a native of Europe and America. The length of this ſpecies is about two feet four, the extent four feet ſix; the bill is elevated, of a pale yellow colour, with a white ring at the baſe; the fore-head is white; the breaſt and belly are of a dirty white, marked with great ſpots of black; and the legs yellow. Theſe viſit the fens and other parts of England during winter, in ſmall flocks; they keep always in marſhy places, and never frequent the corn-lands. They diſappear in the earlieſt ſpring, and none are ſeen after the middle of March.

Linnæus makes this gooſe the female of the *bernacle*; but Mr. Pennant thinks his opinion not well founded.

The *bernacle* (erythropus *mas*, Lin.) is two feet one inch in length, the breadth four feet five inches: the bill is black; the forehead and cheeks are white; from the bill to the eyes, there is a black line; the hind part of the head, the whole neck, and upper part of the breaſt and back, are of a deep black; the tail is black, the legs are of the ſame colour, and ſmall. Theſe birds appear in vaſt flocks during winter, on the north-weſt coaſts of this kingdom: they are very ſhy and wild; but on being taken, grow in a few days as familiar as our tame geeſe. In February they quit our ſhores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed.

10. The race-horſe or loggerhead gooſe, is in length 32 inches, and weighs from 20 to 30 pounds. The bill is three inches long, and of an orange colour: the irides are orange, ſurrounded with black, and then with orange: the head, neck, and upper parts of the body are of a deep aſh-colour; the outer edge of the ſecondaries white, forming a band of the ſame on the wing: the under parts of the body duſky down the middle; over the thighs cinereous blue; vent white; quills and tail black: the wings are very ſhort, not reaching to the rump: on the bend of the wing is a yellow knob, half an inch in length: the legs are browniſh orange, the webs duſky, and the claws black. Theſe inhabit Falkland Iſlands, Staaten Land, &c. and were moſtly ſeen in pairs, though ſometimes they were obſerved in large flocks.

11. The ſnow-gooſe is in length two feet eight inches, and weighs between five and ſix pounds. The bill is ſomewhat ſerrated at the edges; the upper mandible ſcarlet, the lower whitiſh: the general colour of the plumage is ſnow white, except the firſt ten quills, which are black, with white ſhafts: the legs are of a deep red. The young are of a blue colour, till they are a year old. Theſe are very numerous at Hudſon's Bay. They viſit Severn River in May, and ſtay a fortnight; but go farther north to breed.

12. The great gooſe is of a very large ſize, weighing near 25 or 30 Ruſſian pounds. The bill is black; baſe of it tawny: body duſky: the under parts are white; the legs ſcarlet. It is found in the eaſt of Siberia, from the river Lena to Kamtſchatka; and is taken in great numbers, together with the red-necked gooſe, in glades, as we do woodcocks in England, but upon a larger ſcale.

13. The ruficolis, or red-breaſted gooſe, is in length 21 inches; weight three pounds troy. The bill is ſmall, and brown; the tail black: the irides are yellow brown; round the eyes, fringed with brown: fore part of the head and crown black, paſſing backwards in a narrow ſtripe quite to the back: on the breaſt is a narrow band of white feathers with black ends, forming a band of white and another of black; the ſides are ſtriped with black: back and wings black, the laſt even with the tail: legs black. This moſt elegant of geeſe is found to breed from the mouth of the Ob, along the coaſts of the Icy ſea, to that of the Lena. Its winter quarters are not certainly known.

14. The caſarca, or ruddy gooſe, is larger than a mallard, and ſeems even larger than it really is, from the length of wing, and ſtanding high on its legs. The bill is black: the irides are yellowiſh brown: forehead, cheeks, and throat, yellowiſh: fore-part of the neck ferruginous, encircled with a collar of black, inclining to deep rufous on the throat: the breaſt and ſides are pale rufous; the belly is obſcure: the back is pale; the lower part is undulated, hoary, and brown, not very diſtinct; the rump and tail are greeniſh black; the legs long and black. This ſpecies is found in all the ſouthern parts of Ruſſia and Siberia in plenty. In winter it migrates into India, and returns northward in ſpring.

15. The bernicla, is of a brown colour; with the head, neck, and breaſt, black; and a white collar. Theſe birds, like the bernacles, frequent our coaſts in winter; and are particularly plenty, at times, on thoſe of Holland and Ireland, where they are taken in nets placed acroſs the rivers.

16. The canadenſis is brown; its neck and head are black, and the throat is white. It meaſures three and a half feet in length. It is found during the ſummer in Hudſon's Bay, and parts beyond: alſo in Greenland; and, in the ſummer months, in various parts of North America, as far as Carolina. They breed at

Hudſon's Bay, and lay ſix or ſeven eggs; but the major part retire ſtill farther north.

17. The molliſſima, or eider-duck, is double the ſize of the common duck, has a cylindrical bill, and the wax is divided behind, and wrinkled. The feathers, which are very ſoft and valuable, fall off during incubation. The male is white above, but black below and behind: the female is greeniſh. This ſpecies is found in the Weſtern Iſles of Scotland, particularly on Oranſa, Barra, Rona, and Heiſker, and on the Farn Iſles; but in greater numbers in Norway, Iceland, and Greenland; from whence a vaſt quantity of the down, known by the name of *eider* or *edder*, which theſe birds furniſh, is annually imported.

18. The maula, or ſcaup-duck, is leſs than the common duck. The bill is broad, flat, and of a greyiſh blue colour; the head and neck are black; the back, the coverts of the wings, and the ſcapulars, are finely marked with numerous narrow tranſverſe bars of black and grey; the legs are duſky.

19. The moſchata, or Muſcovy duck of Ray, has a naked papillous face, and is a native of India. It is bigger than the wild duck, being in length two feet. This ſpecies is pretty common in a domeſticated ſtate in almoſt every nation.

20. The elypeata, or ſhovelar of Ray, has the end of its bill broad, rounded, and furniſhed with a ſmall hook. It is in length 21 inches; the female a trifle ſmaller. This bird is rather ſcarce in England.

21. The ſtrepera, or gad-wall, has the wings variegated with black, white, and red. It inhabits England in the winter months, and is alſo found at the ſame ſeaſon in various parts of France and Italy. It migrates as far as Sweden as ſummer advances in order to breed; and found throughout Ruſſia and Siberia.

22. The clangula, or golden eye of Ray, is variegated with black and white, and the head is interſperſed with blackiſh green feathers: it has a white ſpot near the mouth; and the eyes are of a ſhining gold colour. It is not unfrequent on our ſea-coaſts in winter, and appears in ſmall flocks; but paſſes to the north in ſpring in order to breed.

It inhabits Sweden and Norway during the ſummer. It is an excellent diver, and feeds on ſmall ſhells. It is moſtly ſeen in the water, as it is very awkward in walking. It has been attempted to be domeſticated, but ſeems out of its element on land. With difficulty it can be brought to eat any thing but bread; and the feet ſoon grow injured, inſomuch as at laſt to hinder it from walking. The fleſh is much eſteemed, and the birds are often ſeen in the markets at the proper ſeaſon. This ſpecies is found in America; in winter, at New York; in ſummer, at Hudſon's Bay, where it frequents the freſh-water lakes, and makes in hollow trees a round neſt of graſs lined with feathers from its breaſt; lays about ten white eggs.

23. The merſa, or Ural duck of Pallas, is ſomewhat bigger than the common teal. The bill is large, broad, very tumid above the noſtrils, and bifid in the adult bird, the end marked with diverging ſtriæ; colour blue; the head, and part of the neck, are white; on the crown is a large patch of black: the middle of the neck is black: the fore-parts of the body are a yellowiſh brown, undulated with black: the back is clouded with a cinereous and pale yellow, powdered with brown; the wings are ſmall; the tail longiſh, wedge-ſhaped, and black: the legs are brown, on the fore-part blueiſh, and placed as far back as in the diver genus. This ſpecies is common to the greater lakes of the Ural mountains, and the rivers Ob and Irtiſch.

24. The American widgeon, *le canard jenſen*, of Bouffon, is rather bigger than our widgeon. The bill is of a lead colour; the crown and forehead of a yellowiſh white; the hind-part of the head and neck is black and white, ſpeckled; and behind the eye is a black mark, changing in ſome lights, to green: the back and ſcapulars are of a pale ruſt-colour, waved with tranſverſe black lines: in the middle of the wing coverts there is a large bed of white; the quills and tail are deep brown; the legs duſky. It inhabits North America, from Carolina to Hudſon's Bay; but it is no where a common bird. It is called at New-York the Pheaſant Duck.

25. The acuta, pin-tail, or ſea-pheaſant of Ray, has a long accuminated tail, black below, with a white line on each ſide of the back part of the head. It is a native of Europe.

26. The glacialis, or long-tailed duck, is inferior in ſize to the former. The bill is ſhort, black at the tip and baſe, orange-coloured in the middle; the cheeks are of a pale brown; the hind-part of the head, and the neck, both before and behind, are white; the breaſt and back are of a deep chocolate colour; the four middle feathers of the tail are black, and two of them near four inches longer than the others, which are white; the legs are duſky. Theſe birds breed in the moſt northern parts of the world; and only viſit our coaſts in the ſevereſt winters.

27. The ferina, pochard, or red-headed widgeon of Ray, has a lead-coloured bill: the head and neck are of a bright gay colour: the breaſt, and part of the back, where it joins the neck, are black: the coverts of the wings, the ſcapulars, back and ſides, under the wings, are of a pale grey, elegantly marked with narrow lines of black; the tail conſiſts of twelve ſhort feathers, of a deep grey colour: the legs are lead-coloured; and the irides of a bright yellow, tinged with red. The head of the female is of a pale reddiſh brown.

They frequent the fens in this country in the winter ſeaſon.

28. The querquela, garganey, or firſt teal of Aldrovandus, has a green ſpot on the wings, and a white line above the eyes. It frequents the freſh waters of Europe. In many places it is called the ſummer teal.

29. The creca, or common teal, has a green ſpot on the wings, and a white line both above and below the eyes. It is of a ſmall ſize, only fourteen inches in length, and is common to our markets.

The teal remains in France throughout the year, and makes a neſt in April among the ruſhes, on the edges of ponds; it is compoſed of the tendereſt ſtalks of them, with the addition of the pith, and a quantity of feathers. The neſt is of a large ſize, and placed in the water, ſo as to riſe and fall with it. The eggs are the ſize of thoſe of a pigeon, of a dirty white, marked with ſmall hazel ſpots. It is ſaid to feed on the graſs and weeds which grow on the edges of the ponds which it frequents, as well as the ſeeds of the ruſhes; it will alſo eat ſmall fiſh. The fleſh is accounted excellent. It is found to the north as high as Iceland; and is mentioned as inhabiting the Caſpian ſea to the ſouth.

30. The hiſtrionica, or duſky ſpotted duck of Edwards, is of a brown colour, variegated with white and blue; it has a double line on the ears and temples; the collar is white, and there is a white ſtreak on the neck. It inhabits from Carolina to Greenland: in the latter it frequents, during ſummer, the rapid rivers, and the moſt ſhady parts; neſtling on the banks, among the low ſhrubs. It ſwims and dives admirably. In winter it ſeeks the open ſea, flies high and ſwiftly, and is very clamorous. It feeds on ſhell-fiſh, ſpawn, and the larvæ of gnats. Is found in Iceland, and as low as Sondmor. It is common from the lake Baikal to Kamſchatka, and breeds there as well as every where elſe.

31. The minuta, or little white and brown duck of Edwards, is of a greyiſh colour, with white ears, and the prime feathers of the wings blackiſh. This and the former, according to Latham, are found both on the old and new continents.

On the firſt it is ſeen as far ſouth as the lake Baikal, and from thence to Kamſchatka, particularly up the river Ochotſka; alſo in Iceland, and as far as Sondmor.

In America, it is found from Carolina to Newfoundland, and Hudſon's Bay; alſo in Greenland, where it frequents, during ſummer, bays and rivers, eſpecially near their mouths, and is a very noiſy ſpecies. It is fond of ſhady places, and makes the neſt on ſhore among the ſhrubs. Its food is ſmall ſhells, eggs of fiſhes, and particularly the larvæ of gnats. It ſwims well, even in the moſt rapid ſtreams, and dives to admiration; it likewiſe flies ſwift, and to a great height; from which circumſtances it is not eaſily taken.

Our late navigators met with it at Aoonalaſhka. It is pretty frequent in the ſmall rivulets of Hudſon's Bay, about 90 miles inland; ſeldom in large rivers. It lays 10 or more white eggs, like thoſe of the pigeon, on the graſs; and the young brood ſpeckled in a very pretty manner. It migrates towards the ſouth in ſummer.

32. The boſchas, common wild-duck of Ray, or mallard; the intermediate tail-feathers of the drake are turned backward, and the bill is ſtreit. It frequents the lakes of different countries, and feeds upon frogs and ſeveral ſorts of inſects. The wild-ducks pair in the ſpring; build their neſts among ruſhes near the water, and lay from 10 to 16 eggs. The female is a very artful bird; and does not always make the neſt cloſe to the water, but frequently at a good diſtance from it; in which caſe the duck will take the young in its beak or between its legs. It is known ſometimes to lay the eggs in a high tree, in a deſerted magpie's or crow's neſt.

At moulting time, when they cannot fly, they are caught in great numbers. They abound particularly in Lincolnſhire, the great magazine of wild fowl in this kingdom; where prodigious numbers are annually taken in the decoys.

Birds with flat bills, that find their food by groping, have three pair of nerves that extend to the end of their bills; theſe nerves are remarkably conſpicuous in the head and bill of the wild-duck, and are larger than thoſe of a gooſe, or any other bird yet known; this is the reaſon aſſigned why they grope for food more than any other bird whatever.

The common tame ſpecies of ducks take their origin from theſe, and may be traced to it by unerring characters. The drakes, however they vary in colours, always retain the colours of the tail, and both ſexes the form of the bill, of the wild kind.

Nature ſports in the colours of all domeſtic animals; and for a wiſe and uſeful end, that mankind may the more readily diſtinguiſh and claim their reſpective property.

In France this ſpecies is not often ſeen, except in winter; appearing in October, and going north in ſpring. They are caught in various manners; among the reſt, in decoys, as in England; the chief place for which is Picardy, where prodigious numbers are taken, particularly on the river Somme. It is alſo cuſtomary there to wait for the flocks paſſing over certain known places, and the ſportſman, having a wicker cage, containing a quantity of tame birds, lets out one at a time, at a convenient ſeaſon, which enticing the paſſengers within gunſhot, five or ſix are often killed at once by an expert markſman. They are now and then taken alſo by a hook baited with a bit of ſheep's lights, which ſwimming on the water, the bird ſwallows the bait, and with it the hook. Various other means of catching ducks and geeſe are peculiar to certain nations; of which one ſeems worth mentioning from its ſingularity: the perſon wiſhing to take theſe, wades into the water up to the chin, and having his head covered with an empty calabaſh, approaches the place where the ducks are; when they, not regarding an object of this ſort, ſuffer the man freely to mix with the flock; after which he has only to pull them by the legs under the water, one after another, till he is ſatisfied; returning as unſuſpected by the remainder as when he firſt came among them. This method is frequently put in practice on the river Ganges, uſing the earthen veſſels of the Gentoos inſtead of the calabaſhes; theſe veſſels are what the Gentoos boil their rice in, and are called Kutcharee pots (they likewiſe make a diſh for their tables in them, which goes by the ſame name): after theſe are once uſed they look upon them as defiled, and in courſe throw them into the river as uſeleſs; and the duck-takers find them convenient for their purpoſe, as the ducks, from conſtantly ſeeing the veſſels float down the ſtream, look upon them as objects of full as little regard as a calabaſh. The above, or ſome ſuch method, is alſo practiſed in China as well as in India. The Chineſe, however, though they make great uſe of ducks, do not prefer the wild ſort, being in general extremely fond of tame ones: and it is ſaid that the major part of theſe are hatched by artificial heat; the eggs, being laid in boxes of ſand, are placed on a brick hearth, to which is given a proper heat during the time required for hatching. The ducklings are fed with little craw-fiſhes and crabs, boiled and cut ſmall, and afterwards mixed with boiled rice; and in about a fortnight ſhift for themſelves, when the Chineſe provide them an old ſtepmother, who leads them where they are to find provender for themſelves; being firſt put on board a ſampane or boat, which is deſtined for their habitation, and from which the whole flock, often to the amount of 300 or 400, go out to feed, and return at command. This method is uſed nine months out of the twelve, for in the colder months it does not ſucceed; and is ſo far from a novelty, that it may be every where ſeen; but more eſpecially about the time of cutting the rice and gleaning the crop, when the maſters of the duck ſampanes row up and down the river according to the opportunity of procuring food, which is found in plenty, at the tide of ebb, on the rich plantations, as they are overflowed at high water. It is curious to ſee how the ducks obey their maſter; for ſome thouſands, belonging to different boats, will feed at large on the ſame ſpot, and on a ſignal given will follow their leader to their reſpective ſampanes, without a ſtranger being found among them. This is ſtill more extraordinary, if we conſider the number of inhabited ſampanes on the Tigris, ſuppoſed to be no leſs than 40,000, which are moored in rows cloſe to each other, with a narrow paſſage at intervals for boats to paſs up and down the river. The Tigris, at Canton, is ſomewhat wider than the Thames at London, and the whole river is there covered in this very ſingular manner for the exent of at leaſt a mile.

33. The galericulata, or Chineſe teal of Edwards, has a hanging creſt; and on the hinder part of the back, on both ſides, there is a crooked, flat, elevated feather; the creſt is green and red; and the back is brown, ſpotted with blue; and erect feathers on the back are red and blunt; one edge of the inmoſt wing feather, when the wings are ſhut, is raiſed over the back, and is red, and like a ſickle before. This moſt ſingular and elegant ſpecies is a native of China and Japan, where it is kept by the inhabitants for the ſake of its beauty.

Attempts have been made to breed them in this country, but without ſucceſs, though they are familiar enough. This bird is known in Japan by the name of Kimnodſui. The Engliſh in China give it the name of Mandarin Duck.

34. The ſponſa, or ſummer duck of Cateſby, is a moſt elegant ſpecies. It has a depending green creſt, variegated with blue and white; the back is likewiſe variegated in the ſame manner; the breaſt is grey, ſpotted with white; and the throat is white. It inhabits Mexico, and ſome of the Weſt India iſles; migrating, in the ſummer ſeaſon, as far north as 40 degrees.

35. The aborea, or black-billed whiſtling duck of Edwards, is of a reddiſh brown colour, with a ſort of creſt on the head; the belly is ſpotted with black and white. It is a native of America.

36. The fuligula, or tufted duck of Ray, has a hanging creſt, a black body, and the wings and belly ſpotted with white. In the winter months it is not unfrequent in England; being met with in the markets in that ſeaſon, and is much eſteemed.

There are 62 other ſpecies enumerated by ornithologiſts; the whole number hitherto deſcribed being 98.

ANASARCA, among phyſicians, a ſpecies of the dropſy.

ANASSAS, in natural hiſtory, the name given by the natives of Guinea to the pine-apple; where it is ſaid to grow in the greateſt perfection, without any cultivation whatever.

ANASTASIS, a term among ancient phyſicians, for a riſing up to go to ſtool. It alſo ſignifies the paſſage of any humour, when expelled from one part, and obliged to remove to another. In Engliſh the word is the ſame as RESURRECTION.

ANASTATICA, the ROSE OF JERICHO, a genus of the ſiliculoſa order, belonging to the tetradynamia claſs of plants; and, in the natural method, ranking under the 39th order, Siliquoſæ. There are two ſpecies:

1. The ſyriaca, a native of Syria, is not cultivated or known in Britain.

2. The hierochuntica is a native of the ſandy parts of Paleſtine and the Red Sea. It is a low annual plant, dividing into many irregular woody branches near the root. At each joint is placed a ſingle, oblong, hairy leaf; and at the ſame places come out ſmall ſingle flowers, of a whitiſh green colour, compoſed of four leaves, placed in the form of a croſs. Theſe are ſucceeded by ſhort wrinkled pods, having four ſmall horns; theſe open into four cells, in each of which is lodged a ſingle brown ſeed. It is propagated by ſeeds.

ANASTOMATICS, in medicine, denotes ſuch applications as have been the power of opening the mouths of the veſſels, and promoting the circulation; ſuch as deobſtruent, cathartic, and ſudorific medicines.

ANASTOMOSIS, in anatomy, implies the opening of the mouths of veſſels, in order to diſcharge their contained fluids. It is likewiſe uſed for the communication of two veſſels at their extremities; as the inoculation of a vein with a vein; of an artery with an artery; or of an artery with a vein, &c.

ANASTROPHE, in rhetoric, denotes the inverſion of the natural order of words.

ANATHEMA, among eccleſiaſtical writers, imports whatever is ſet apart, ſeparated, or divided; but is moſt uſually meant to expreſs the cutting off a perſon from the privileges of ſociety and communion with the faithful.

The anathema differs from excommunication in the circumſtances of being attended with curſes and execrations. It was practiced in the primitive church againſt notorious offenders; and the form of that pronounced by Synecius againſt one Andronicus, is as follows: "Let no church of God be open to Andronicus, but let every ſanctuary be ſhut againſt him. I admoniſh both private men and magiſtrates, to receive him neither under their roof, nor to their table; and prieſts more eſpecially, that they neither converſe with him living, nor attend his funeral when dead."

Several councils alſo have pronounced anathemas againſt ſuch as they thought corrupted the purity of the faith: and their deciſions have been conceived in the following form:

Si quis dixerit, &c. anathema ſit.

There are two kinds of anathemas, the one judiciary, and the other abjuratory. The former can only be denounced by a council, a pope, or a biſhop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the hereſy he abjures.

ANATHEMA, in heathen antiquity, was an offering or preſent made to ſome deity, and hung up in the temple. Whenever a perſon left off his employment, it was uſual to dedicate the tools to the patron-deity of the trade. Alſo, perſons who had eſcaped from imminent danger, as ſhipwreck and the like, or had met with any other remarkable inſtance of good fortune, ſeldom failed to teſtify their gratitude by ſome preſent of this kind.

ANATHEMATIZING, the act of pronouncing anathemas.

ANATHEMATISM, denotes the ſame as ANATHEMA.

ANATICULA, in Greek and Roman antiquity, implies a word of tenderneſs, as, my little dear, &c.

ANATIFERA CONCHA, the trivial name of a ſpecies of the lepas, a teſtaceous animal.

ANATOCISM, ANATOCISMUS, an uſurious contract, wherein the intereſts ariſing from the principal ſum are added to the principal itſelf, and intereſt exacted upon the whole. The word is originally Greek, but uſed by Cicero in Latin; whence it is deſcended into moſt other languages. It comes from the prepoſition *ανα*, which in compoſition ſignifies repetition or duplication, and *τοκος*, uſury. Anatociſm is what we call, intereſt upon intereſt, or compound intereſt. This is the worſt kind of uſury, and has been ſeverely condemned by the Roman law, as well as by the common laws of moſt other countries. See INTEREST.

ANATOMY, *ανατομη*, the art of diſſecting, or artificially ſeparating the parts of an animal body, to diſcover their ſituation, figure, connections, fabric, and œconomy. This term is uſually applied to the examination of the ſtructure of human bodies. Where its ſubject is a deſcription of the ſtructure of the brute creation, it is denominated *Comparative* ANATOMY.

The following Syſtem of Anatomy is the ſelection and arrangement of Mr. HALL, *Member of the Corporation of Surgeons, and Profeſſor of Anatomy, in Broad-Street, Golden-Square.*

A NEW SYSTEM of ANATOMY.

THE Science of Anatomy might date its origin as far back as the firſt formation of ſociety; for it appears that the mind of man very ſoon applied itſelf to the attainment of anatomical knowledge: and the names, uſes and ſituations of the external parts of our bodies were probably among the firſt of our acquired ideas.

If we examine the attainment of the leaſt cultivated race of ſavages that have been hitherto diſcovered, we ſhall find among them conſiderable knowledge of the external ſtructure of the body; and that they have not only affixed names to many of thoſe parts, but have juſt ideas as to their ſituations and uſes: likewiſe, from their obſervations on the ſtructure of the animals which they deſtroy in their hunting, they may have ſome ideas of the internal ſtructure of the human body; and from the conſequence of their wars they muſt occaſionally inſpect even human bodies. Thus Dr. Hunter uſed to relate that Omiah, when he viſited his muſeum, evinced a knowledge of the uſes of moſt parts of the body, and particularly deſired to examine the organs of generation. So that a South-Sea iſlander, placed at the remoteſt diſtance from Science, was not found to be totally ignorant of Anatomy.

Admitting the foregoing obſervations to be founded on reaſon, and they appear ſelf-evident, it will be found that the knowledge of Anatomy had its beginning with the firſt eſtabliſhment of ſociety in the world; and that it has gradually accumulated ſince that time, in proportion to the labours or abilities of the different men who have profeſſed that art; and would have arrived much ſooner at a notable degree of perfection, had not the collected knowledge of ages been repeatedly diſſipated, by the ſudden overthrow, and almoſt total annihilation of ſtates, which were ſo frequently taking place in the early periods of civilization.

This appears ſtill more evident to our ſenſes, when we conſider, that the ſtate of knowledge was merely traditional, and handed down from father to ſon, and in that way, by a ſeries of experience, ſome families became famous in one art, and ſome in another; and made conſiderable improvements in their ſeveral profeſſions.

In this ſtate of a nation, a ſucceſsful war, carried on by a barbarous neighbour, would not only deſtroy their mode of government, but, as it were, annihilate the whole people, who were either ſlain, or carried into captivity; and thus their increaſing traditional knowledge would become extinct; for we cannot ſuppoſe that ſlaves, who met with the moſt cruel treatment, would inſtruct their barbarous maſters, but rather, from a principle of revenge, ſuffer their knowledge to die with them.

In the early ages of Greece Anatomy had made great advances in improvement, as appears from the juſt deſcriptions of the effects of wounds, which Homer has repeatedly given.

The ſources from whence this knowledge of Anatomy ſprang are numerous: in the earlieſt ages of the world, and according to Holy Writ, even in the days of Adam, animals were ſacrificed to the Deity; and in the performance of this ceremony, conſiderable art was neceſſary to ſeparate thoſe parts which were not acceptable in the ſacrifice, from thoſe which were ordained to be made uſe of.

By theſe means the internal parts of animals were frequently expoſed to the deliberate examination of the ſacrifice.

After the flood, when man began to eat animal food, anatomical knowledge muſt have been yet further improved, as the butchery gave the greateſt opportunities to inquiſitive men of informing themſelves with reſpect to the ſtructure of animals; and accidents frequently happened which gave opportunities of inſpecting human bodies; ſuch as a man particularly devoured by wild beaſts, or ſlain by the enemy in battle, or from the barbarous modes of executing criminals, which are generally practiſed by uncivilized nations. Add to theſe, the cuſtom of embalming in common uſe among the Egyptians, from which practice an increaſing ſtock of anatomical knowledge muſt have gradually ariſen.

From a conſideration of all theſe circumſtances, it does not appear wonderful that Mercurius Ægyptianus king of the Thebans, ſhould have been able to have wrote ſeveral volumes, or ſkins of parchment, on the ſubject of Anatomy, which were placed in the Temple of Memphis, a thouſand years before the time of Eſculapius: theſe are the firſt writings on that ſcience, whoſe remembrance is recorded in hiſtory, ſo that Anatomy, in the days of Homer, was a very ancient ſcience.

Hippocrates, the Father of Phyſic, wrote many detached pieces on the ſubject of Anatomy, and endeavoured to advance the knowledge of that ſcience; but ſome of them are more eſteemed for their antiquity than their real merit, as his deſcriptions of the Viſcera are little more than a recapitulation of their names; the ſame may be ſaid of his deſcription of the Nerves and Blood Veſſels: his account of the Heart is particular, and pretty accurate; but Galen and Eraſiſtratus deny its being the genuine Work of Hippocrates. However, his deſcription of the Bones, and their joints, are given with great preciſion, and enriched with many uſeful obſervations on the treatment of Fractures and Diſlocations.

Ariſtotle, by a love of ſtudy, and extraordinary opportunities of purſuing his enquiries, added much to the maſs of philoſophical knowledge. He flouriſhed about 360 years before Chriſt, and from the fame that he had acquired in philoſophy, was appointed preceptor to Alexander the Great, after the death of his maſter Plato. He wrote upon Anatomy, but chiefly comparative; and advanced the ſcience by a judicious and exact hiſtory of the incurbated egg; and by his deſcription of the human fœtus, and the gradual completion of its organized parts, ſo as to be evidently the founder of the Anthropagenetical Syſtem, which implies, a ſucceſſive organization and appoſition of the parts, a doctrine that was eſpouſed by his admirer Dr. Harvey.

We ſhould pay the more attention to the ſentiments of Ariſtotle in his anatomical deſcription of Animals, becauſe he was not only an ardent lover of that ſcience, but was poſſeſſed of wealth; therefore had the means of examining almoſt all animals by the generoſity of Alexander. He allowed him 800 talents, near 2,000,000*l.* ſterling, to procure and maintain a variety of animals, in order to obſerve their manners and genius whilſt living, and to examine their anatomical ſtructure when dead.

Diocles Caryotius, who lived ſoon after the time of Ariſtotle, according to Galen, was the firſt author who wrote on the method of diſſecting bodies; this art, before his time, being confined to private families, and only taught to the children and pupils of thoſe who poſſeſſed the ſecret. From hence he ought to have high rank among the primitive anatomiſts; he might even claim the title of the Father of Anatomy, becauſe he firſt divulged to the public the only means of acquiring knowledge and making improvements in the art; but his works having been deſtroyed by the conflagration of the Alexandrian library, he has almoſt ſunk into oblivion. He was called by the Athenians the ſecond Hippocrates. He recommended the ſwallowing of a ball of lead for the cure of the iliac paſſion, which ſeems to prove his knowledge of the nature of the diſeaſe, as acquired by diſſection.

Thus by the obſervations and improvements of Hippocrates, Ariſtotle, and Diocles Caryotius, this ſcience was put in a train for advancement, and by the labours and genius of many of their ſucceſſors the knowledge of Anatomy has been gradually brought to its preſent ſtate of perfection.

Harvey's diſcovery of the Circulation of the Blood in the laſt century is a memorable æra in the hiſtory of this art, and has deſervedly affixed immortality to his name.

The full knowledge of the Abſorbent Syſtem has graced the Anatomiſts of the preſent century, and has added much to our knowledge of the Animal Œconomy.

The name of Hewſon, like that of Harvey, will be long remembered for having firſt proved the exiſtence of thoſe veſſels in birds, amphibiæ and fiſh, as well as in the human body.

The mode of teaching this ſcience is, practically, as follows:

1. That which is called the Synthetic, or where we begin with the whole body, and diſplay the parts gradually by diſſection.
2. The Analytic, or where we firſt deſcribe the elements of the body, and then proceed to conſider the whole machine.

The ancients made uſe of the former of theſe methods; but this is now generally laid aſide, becauſe it uſually requires ſeveral bodies to explain all the parts, and an examination of the muſcles or blood veſſels is as much as we can do upon one ſubject; at the ſame time it often requires the removal of one part to diſplay another, which renders it impoſſible to ſee every part of the ſame ſubject.

In our plan we ſhall follow the Analytic method; we ſhall firſt conſider the conſtituent parts that make up the general organization: then the general properties of ſimilar parts, ſuch as Artery, Muſcle, Bone, &c. and, laſtly, give a particular deſcription of each part ſeparately, under the following heads:

I. GENERAL OBSERVATIONS

On the moſt Simple Component Parts of the Body.

II. OSTEOLOGY;

Or a particular Deſcription of the Bones.

III. MYOLOGY;

Or a particular Deſcription of the Muſcles and the Male Organs of Generation.

IV. ANGIOLOGY;

Or a Deſcription of the Vaſcular Syſtems.

V. SPLANCHNOLOGY;

Or a Deſcription of the Viſcera, with the Female Organs of Generation.

VI. NEUROLOGY;

Or the Doctrine of the Nerves, and the Organs of Senſe.

Thus we ſhall endeavour to arrange the human body in ſuch a way as to enable the ſtudent to examine the human body in the moſt natural order, and by that means to facilitate his progreſs in the ſcience; attending throughout the whole to perſpicuity and conciſeneſs, that we may inform the mind, rather than give a vain diſplay of deep reading and prolixity, which could only tend to divert the fancy.

ANATOMY.

PART I.

GENERAL OBSERVATIONS ON THE MOST SIMPLE COMPONENT PARTS OF THE BODY.

SECT. I.

ON NUTRITION.

THE variety of functions which are inceſſantly performed by the living body, and the continual circulation of the blood through it, muſt neceſſarily occaſion a conſtant diſſipation of the ſeveral parts which enter into its compoſition.

The fluids are conſtantly waſting, as is evident from the great exhalation that is daily going on from the ſkin by inſenſible perſpiration, and from the lungs by expiration. Alſo from the evacuation of urine, ſaliva, &c.

But the ſolid, as well as the fluid parts of the body, require a conſtant renewal of nutritious particles. They are expoſed to the attrition of the fluids which are circulated through them, and the contraction and relaxation they repeat ſo many thouſand times in every day, would neceſſarily occaſion a diſſolution of the machine, if the renewal was not proportioned to the waſte.

The Blood is the ſource of nutrition, containing in its compoſition the elements of every part of the body. This fluid has a continual ſupply of nutritious particles from the chyle, ſo long as health remains.

If the ſupply of nouriſhment exceeds the degree of waſte, the body increaſes; and this happens in infancy and in youth: for at thoſe periods, but more particularly the former one, the fluids bear a large proportion to the ſolids; and the fibres being ſoft and yielding, are proportionably more capable of extenſion and increaſe. But when the ſupply of nutrition only equals the waſte, we neither increaſe nor decreaſe; and we find this to be the caſe, when the body has attained its full growth, or *acme*; for the ſolids having then acquired a certain degree of firmneſs and rigidity, do not permit a farther increaſe of the body. But as we approach to old age, rigidity begins to be in exceſs, and the fluids bear a much leſs proportion to the ſolids than before. The diſſipation of the body is greater than the ſupply of nouriſhment: many of the ſmaller veſſels become gradually impervious; and the fibres loſing their moiſture and elaſticity, appear flaccid and wrinkled. The florid complexion diſappears, becauſe the fluids by which they were produced can no longer reach the extremities of the capillary veſſels of the ſkin. As theſe changes take place, the nervous power being proportionably weakened, the irritability and ſenſibility of the body, which were formerly ſo remarkable, are greatly diminiſhed; and, in advanced life, the hearing, the eye-ſight, and all the other ſenſes become gradually impaired.

The length of man's life depends upon nutrition, where no particular diſeaſe intervenes to put a period to it; and this is frequently performed with energy for ſeventy years, but it has been continued for a much longer ſpace of time; as in the caſe of Thomas Parr, who lived 152 years, and acted the part of a huſband to the age of 132 years.

In this ſection, as alſo in the following, we have, in order to elucidate the ſubjects, made various quotations from Dr. *Simmons*'s tranſlation of *Elements d'Anatomie raiſonnée, par M. Perſon*.

SECT. II.

ON THE BLOOD.

BLOOD, recently drawn from a vein into a baſon, would ſeem to be an homogeneous fluid of a red colour; but when ſuffered to reſt, it ſoon coagulates, and divides into two parts, which are diſtinguiſhed by the names of *craſſamentum* and *ſerum*. The craſſamentum is the red coagulum, and the ſerum is the water in which it floats. The craſſamentum may be ſubdivided into two parts, for, by being repeatedly waſhed in warm water, it gives out all its red particles, and what remains appears to be compoſed of the *coagulable lymph*.

The red particles have been improperly called globules, they not being of a ſpherical figure, but more like a cheeſe or piece of money. They are very minute, being no more than the 3240th part of an inch in diameter. See Hewſon.

The coagulating lymph becomes a jelly whenever it is at reſt, either in or out of the body, and in every degree of heat. The more it is agitated, the leſs is its diſpoſition to coagulate: hence, in all diſeaſes where the heart is acting ſtrongly, blood drawn from a vein is ſo long before it coagulates, that the red particles ſubſide to the bottom, whilſt the coagulating lymph occupies the upper ſurface of the craſſamentum, forming the buff.

The ſerum is principally made up of water, and a coagulable matter, with certain ſaline particles. This never coagulates in a leſs heat than 160 degrees of Farenheit's thermometer.

The ſerum and craſſamentum differ in their proportion in different conſtitutions; in a ſtrong perſon the craſſamentum is in a greater proportion to the ſerum than in a weak one, and in certain diſeaſes the ſame difference is obſerved.

SECT. III.

ON THE ARTERIES.

AN Artery is a ſtrong elaſtic ramifying tube ariſing from the heart. The Arteries are properly but two, and riſe from the two ventricles of the heart; one of them is called Aorta, or great Artery, proceeding from the left ventricle of the heart, of which all other Arteries, except the pulmonary, are but the branches. From the heart it extends itſelf, by its various branches, to the moſt diſtant parts of the body. The other is named the Pulmonary Artery, for it ſprings from the right ventricle of the heart, and is wholly confined to the lungs.

The figure of an artery ſomewhat reſembles a tree; the ſmaller ramification of the Arteries frequently anaſtamoſe with each other, as may be obſerved in the coats of the inteſtines, when they are injected. The largeſt appearances of this kind are in the Vertebral Arteries, which unite in the ſkull.

All the Arteries in the body are continuations of the ſame tube, which begins at the ventricle of the heart, and gradually divide into branches, and theſe branches grow ſmaller the farther they are from the heart.

Arteries terminate three ways: the moſt common is that into veins: the ſecond termination is into cells, as in *corpora cavernoſa penis*, &c. or the beginning of the excretory ducts of glands. The third termination is on the ſurfaces of parts, whoſe open mouths are called exhalent Arteries.

The Arteries generally lie deep, and always run on the inflected ſide of the limb, as in the Axilla, the inner part of the Cubit, &c. This ſituation prevents their being either ſtretched or compreſſed in the various motions of the body.

In the beginning of each Artery there are three valves, which appear like purſes, and prevent the return of the blood to the heart; the other parts of the Arteries are free from valves.

The coats of the Arteries are three in number.

1. The external, which contains a great number of blood veſſels, and many nerves run through it: it is elaſtic, and its fibres run quaquavaſum.

2. The middle is made of fibres, which are diſpoſed nearly circular, and parallel to each other.

3. The internal is a thin membrane, whoſe ſurface is very ſmooth, to give an eaſy paſſage to the blood.

The cellular membrane is improperly numbered among the coats of the Arteries, for it only connects the real ones.

The coats of Arteries have great elaſticity, by which they preſs on the blood, and powerfully aſſiſt in keeping up the impetus it receives from the contraction of the ventricles of the heart. They have alſo a muſcular power, which is able to contract them beyond their elaſticity, as is evident in the Arteries of an animal bled to death ſlowly, the large Arteries appearing in that caſe almoſt without cavity.

The beginning of the Aorta is furniſhed with ſemilunar valves, as the Pulmonary Artery is, and the ſame triangular bodies to cloſe up the little ſpace left by the valves. Theſe prevent the blood from being forced back upon the heart, which would otherwiſe happen at the time of its relaxation.

SECT. IV.

ON VEINS IN GENERAL.

A VEIN is a thin, ramifying elaſtic tube, which ariſes in the extremities of the body, and terminates in the heart. The blood is diſtributed all over the body by two arteries, the Aorta and the Pulmonary Artery, and is returned by ſix veins, the two Venæ Cavæ, and the four Pulmonary Veins.

In general, the Arteries have their correſpondent Veins, ſo the courſe of the one is known by that of the other.

Veins begin where Arteries end, and proceed from the branches to the trunk, making a canoid figure in the ſame way that the Arteries have been ſaid to do.

The Veins which are ſubject to frequent compreſſion from the action of the muſcles, have valves which open towards the heart; in all the Veins alſo which are perpendicular to the horizon, except thoſe of the abdomen, thorax and pelvis, are valves with their mouths towards the heart. Theſe valves prevent the regurgetation of the blood from the heart.

Thus we ſee the valves of arteries prevent the return of the blood upon the heart, and force it towards the extreme veſſels, whilſt thoſe of the Veins have a contrary effect, ſtopping the current towards the extremities, whilſt they do not impede the return of the blood to the heart; but in both caſes coinciding to facilitate the regular and accuſtomed circulation.

Beſides the deep ſeated Veins which accompany the arteries in the extremities, there are other Veins more ſuperficially ſeated, the reaſon of which is to prevent the circulation being interrupted by the action of the muſcles compreſſing the internal Veins. For the ſame reaſon alſo they anaſtomoſe very frequently with each other by large trunks.

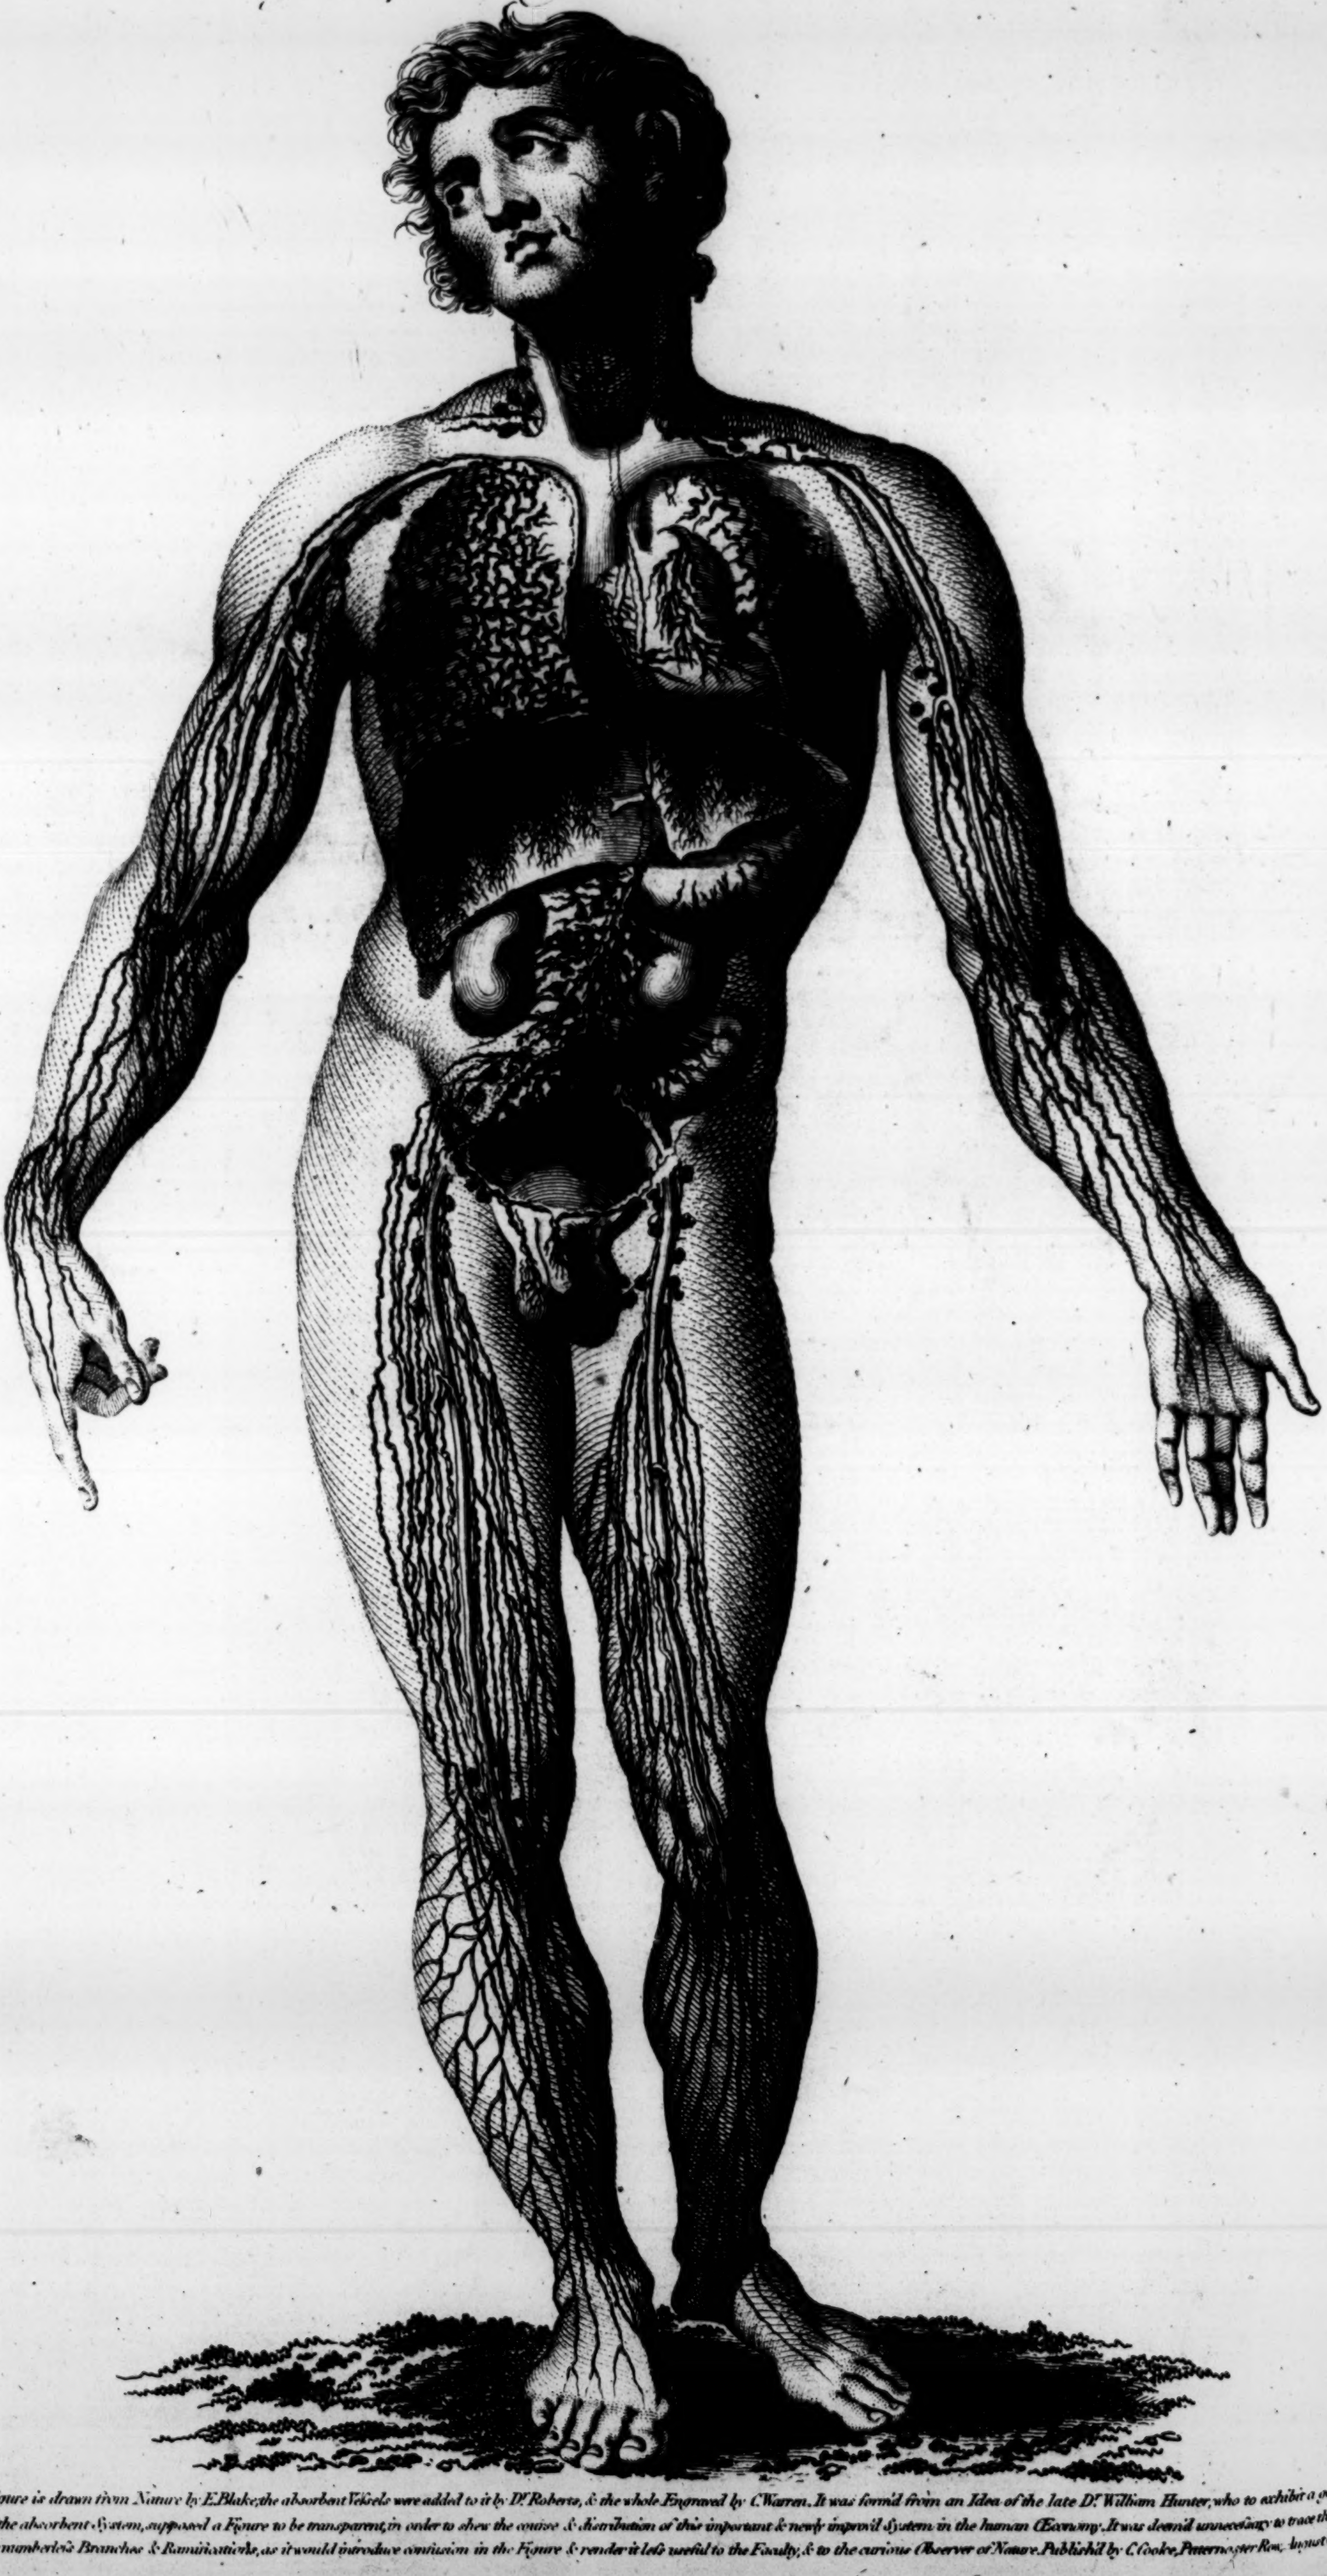
18 MR 63
MUSEUM

Representation of the Absorbent Veſsels: See the Article Lymphatics, and the System of Anatomy, Part 1, Section 5, and Part 4, Section 3.



This Figure is drawn from Nature by E. Blake; the absorbent Veſsels were added to it by Dr. Roberts, & the whole Engraved by C. Warren. It was form'd from an Idea of the late Dr. William Hunter, who to exhibit a general view of the absorbent System, supposed a Figure to be transparent, in order to shew the course & distribution of this important & newly improv'd System in the human Œconomy. It was deem'd unneceſsary to trace the Trunks to their numberleſs Branches & Ramifications, as it would introduce confusion in the Figure & render it leſs useful to the Faculty, & to the curious Observer of Nature. Publish'd by C. Cooke, Paternoster Row, August 6th 1790.

The coats of the Veins are the ſame as thoſe of the arteries; but they are thinner, by being compoſed of fibres in all directions; they bear ſtretching better than the artery, whoſe chief ſtrength is in the circular fibres. The coats of the Veins are thicker in the extremities than among the viſcera, particularly the vena ſtaphœna is of a remarkable thickneſs.

The capacity of the veins is much larger than the arteries, except the pulmonary veſſels, where the four Veins taken together are not equal to the artery.

SECT. V.

ABSORBENT SYSTEM.

WE have deſcribed arteries conveying the blood from the heart, and veins returning it back to that viſcus. There is in the body a third ſeries of veſſels which are univerſally diſtributed, whoſe function is to abſorb every where certain particles, and convey them into the large veins near the heart.

This is called the Abſorbent Syſtem, becauſe it is the only ſet of veſſels in animals that perform that office. This Syſtem is divided into three parts: LACTEALS, LYMPHATICS, and THORACIC DUCT.

LACTEALS.

An infinite number of very minute veſſels, called the Lacteal Veſſels, ariſe like net-work from the inner ſurface of the inteſtines, (but principally from the jejunum and ileum) which are deſtined to imbibe the nutritious fluid or chyle. Theſe veſſels, which were diſcovered by Aſellius in 1622, paſs obliquely through the coats of the inteſtine, and running along the myſentery, unite as they advance, and form larger branches, all of which paſs through the meſenteric or conglobate glands, which are very numerous in the human ſubject. As they run between the inteſtines and theſe glands, they are ſtyled *venæ lacteæ primi generis:* but after leaving theſe glands, they are found to be leſs numerous, and being increaſed in ſize, are then called *venæ lacteæ ſecundi generis,* which go to depoſit their contents in the Thoracic Duct, through which the chyle is conveyed into the blood.

THORACIC DUCT.

This Thoracic Duct begins about the lower part of the firſt vertebra lumborum, from whence it paſſes up by the ſide of the aorta, between that and the vena azygos, cloſe to the vertebræ, being covered by the pleura. Sometimes it is found divided into two branches; but they uſually unite again into one canal, which opens into the junction of the left ſubclavian and left jugular veins, after having run a little way, in an oblique courſe, between its coats. The ſubclavian vein communicates with the vena cava, which paſſes to the right auricle of the heart.

The lower part of this duct, being uſually larger than any other part of it, has been named the *receptaculum chyli*, or *Pecquet's receptacle*, in honour of the anatomiſt who firſt diſcovered it in 1651. In ſome quadrupeds, in turtle and in fiſh, this enlargement is more conſiderable in proportion to the ſize of the duct, than it uſually is in the human ſubject, where it is not commonly found large enough to merit the name of *receptaculum*.

Opportunities of obſerving the Lacteals in the human ſubject do not often occur; but they may be eaſily demonſtrated in a dog, or any other quadruped, that is killed two or three hours after feeding upon milk, for then they appear filled with white chyle.

But theſe Lacteals, which we have deſcribed as paſſing from the inteſtines, through the meſentery, to the Thoracic Duct, compoſe only a part of a Syſtem of Veſſels which perform the office of Abſorption, and which conſtitute, with their common trunk, the Thoracic Duct, and the conglobate glands that are diſperſed through the body, what may be ſtyled the Abſorbent Syſtem. So that what is ſaid of the ſtructure of one of theſe ſeries of veſſels may very properly be applied to that of the other.

LYMPHATICS.

The Lymphatic Veſſels are minute pellucid tubes, which, like the Lacteals, direct their courſe towards the centre of the body, where they pour a colourleſs fluid into the Thoracic Duct. The Lymphatics from all the lower parts of the body gradually unite as they approach this duct, into which they enter by three or four very large trunks, that ſeem to form the lower extremity of this canal, or *receptaculum chyli,* which may be conſidered as the great trunk of the Abſorbent Syſtem. The Lacteals open into it near the ſame place; and the Lymphatics, from a large ſhare of the upper parts of the body, pour their lymph into different parts of this duct as it runs upwards, to terminate between the left ſubclavian and left jugular vein. The Lymphatics, from the right ſide of the neck, thorax, and right arm, &c. terminate in the right ſubclavian vein.

The coats of theſe veſſels are too thin to be ſeparated from each other; but the mercury they are capable of ſuſtaining, proves them to be very ſtrong; and their great power of contraction, after undergoing conſiderable diſtenſion, together with the irritability with which Baron Haller found them to be endued, ſeems to render it probable, that, like the blood-veſſels, they have a muſcular coat.

The Lymphatics are nouriſhed after the ſame manner as all the other parts of the body. For even the moſt minute of theſe veſſels are probably ſupplied with ſtill more minute arteries and veins.

Both the Lacteals, Lymphatics, and Thoracic duct, are furniſhed with valves, which are much more common in theſe veſſels than in the red veins. Theſe valves are uſually in pairs, and ſerve to promote the courſe of the chyle and lymph towards the Thoracic Duct, and to prevent its return. Mention has been made of the glands, through which the Lacteals paſs in their courſe through the meſentery; and it is to be obſerved, that the Lymphatics paſs through ſimilar glands in their way to the Thoracic Duct. Theſe glands are all of the conglobate kind, but the changes which the chyle and lymph undergo in their paſſage through them, have not yet been aſcertained.

The Lymphatic Veſſels begin from ſurfaces and cavities in all parts of the body as abſorvents. This is a fact now univerſally allowed; but how the fluids they abſorb are poured into thoſe cavities, is a ſubject of controverſy. The contents of the abdomen for inſtance, are deſcribed as being conſtantly moiſtened by a very thin watery fluid. The ſame thing takes place in the pericardium, pleura, and all the other cavities of the body, and this watery fluid is the lymph; which, in a ſtate of health, is as conſtantly abſorbed; but where the abſorbents do not perform this action, a dropſy is the conſequence.

The lymph, from its tranſparency and want of colour, would ſeem to be nothing but water; and hence the firſt diſcoverers of theſe veſſels ſtyled them *ducti aquoſi:* but experiments prove, that the lymph of an healthy animal coagulates by being expoſed to the air, or a certain degree of heat, and likewiſe by being ſuffered to reſt; ſeeming to agree, in this property, with that part of the blood called the coagulable lymph. This property of the lymph leads to determine its uſe, in moiſtening and lubricating the ſeveral cavities of the body in which it is found; and for which, by its gelatinous principle, it ſeems to be much better calculated, than a pure and watery fluid would be, for ſuch it has been ſuppoſed to be by ſome Anatomiſts.

The mouths of the Lymphatics and Lacteals, by acting as capillary tubes, ſeem to abſorb the lymph and chyle ſomewhat in the ſame manner as a capillary tube of glaſs, when put into a baſon of water, is enabled to attract the water into it to a certain height: but it is probable, that they likewiſe poſſeſs a living power, which aſſiſts in performing this office. In the human body the lymph, or chyle, is probably conveyed, upon this principle, as far as the firſt pair of valves, which ſeem to be placed not far from the orifice of the abſorbing veſſel, whether lymphatic or lacteal; and the fluid will then be propelled forwards, by a continuation of the abſorption at the orifice. But this does not ſeem to be the only inducement to its progreſs towards the Thoracic Duct; theſe veſſels have, probably, a muſcular coat, which may ſerve to preſs the fluid forwards from one pair of valves to another; and as the large Lymphatic Veſſels and the Thoracic Duct are placed cloſe to the large arteries, which have a conſiderable pulſation, it is reaſonable to ſuppoſe, that they derive ſome advantages from this ſituation, as alſo from the action of muſcles.

SECT. VI.

ON THE GLANDS AND SECRETIONS.

THE Glands are commonly underſtood to be ſmall, roundiſh, or oval bodies, formed by the convolution of a great number of veſſels, and deſtined to ſeparate particular humours from the maſs of blood.

They are uſually divided into two claſſes, but it ſeems more proper to diſtinguiſh three kinds of Glands, viz. the mucous, conglobate, and conglomerate.

The Mucous Glands, or Follicles, as they are moſt commonly called, are ſmall cylindrical tubes, continued from the ends of arteries. In ſome parts of the body, as in the tonſils, for example, ſeveral of theſe follicles may be ſeen folded together in one common covering, and opening into one common ſinus. Theſe follicles are the veſſels that ſecrete and pour out mucus in the mouth, œſophagus, ſtomach, inteſtines, and other parts of the body.

The Conglobate Glands are peculiar to the abſorbent Syſtem. Every abſorbent veſſel paſſes through a gland of this kind in its way to the thoracic duct. They are met with in different parts of the body, particularly in the axilla, groin and meſentery, and are either ſolitary, or in diſtinct cluſters.

The Conglomerate Glands are of much greater bulk than the Conglobate, and ſeem to be an aſſemblage of many ſmaller glands. Of this kind are the liver, kidnies, &c. Some of them, as the pancreas, parotids, &c. have a granulated appearance. All the Conglomerate Glands are plentifully ſupplied with blood veſſels and abſorbents, but their nerves are in general very minute, and few in number. Each little granulated portion furniſhes a ſmall tube, which unites with other ſimilar ducts, to form the common excretory duct of the Gland.

Two Syſtems of Glandular Secretions have been formed, each of which had, and ſtill continues to have its adherents.

One of theſe Syſtems was advanced by Malpighi, who ſuppoſed that an artery, entering into a gland, ramifies very minutely through its whole ſubſtance; and that its branches ultimately terminate in a veſicular cavity or follicle, from whence the ſecreted fluid paſſes out through the excretory duct.

This doctrine at firſt met with few opponents; but the celebrated Ruyſch, who firſt attempted minute injections with wax, afterwards diſputed the exiſtence of theſe follicles, and aſſerted, that every Gland appears to be a continued ſeries of veſſels, which after being repeatedly convoluted in their courſe through its ſubſtance, at length terminate in the excretory duct. Anatomiſts are ſtill divided between theſe two Syſtems.

The mode of Secretion has been explained in a variety of ways, and they are all equally hypothetical. In ſuch an enquiry, it is natural to aſk, how one Gland conſtantly ſeparates a particular humour, while another Gland ſecretes one of a very different nature and both from the blood? The bile, for inſtance, is ſeparated by the liver, and the urine by the kidnies. Are theſe Secretions to be imputed to any particular diſpoſition in the fluids, or is their cauſe to be looked for in the ſolids?

It has been ſuppoſed, that every Gland contains within itſelf a fermenting principle, by which it is enabled to change the nature of the blood it receives, and to endue it with a particular property. Can fermentation go on without expoſure to air?

The theory of Glandular Secretion, by filtration, from a peculiar attraction in a Gland, is equally vague. For many different fluids will paſs through the ſame ſtrainer.

Filtration, by the difference in the diameters of the veſſels of a Gland, is no ways ſatisfactory. Every hypotheſis that has been advanced on this ſubject, leaves many doubts in an unbiaſſed ſtudent; and we muſt know more of the animal œconomy, before this can be fully cleared up; and it has been argued, that the veſſels of the liver, for inſtance, would, upon this principle, afford a paſſage not only to the bile, but to all the other humours of leſs conſiſtence with it. In reply to this objection it has been ſuppoſed, that ſecondary veſſels exiſt, which originate from the firſt, and permit all the humours thinner than the bile to paſs through them.

Each of theſe hypotheſes is probably very remote from the truth.

SECT. VII.

ON THE CELLULAR MEMBRANE AND FAT.

THE Cellular Membrane is founded to inveſt the moſt minute fibres we are able to trace; ſo that by modern phyſiologiſts, it is very properly conſidered as the univerſal connecting medium of every part of the body.

It is compoſed of an infinite number of minute cells united together, and communicating with each other, which are conſtantly lubricated by a fluid ſecreted from the open mouths of the exhalent arteries; this is diſtinguiſhed by the name of interſtitial fluid. The two diſeaſes, peculiar to this Membrane, are proofs of ſuch a communication; for in the emphyſema all its cells are filled with air, and in the anaſarca they are univerſally diſtended with water. Beſides theſe proofs of communication from diſeaſe, a familiar inſtance of it may be obſerved amongſt butchers, who uſually puncture this Membrane, and by inflating it with air, add to the good appearance of their meat.

The cells of this Membrane contain ſmall veſicles, which are called *cellulæ adipoſæ*, and ſerve as reſervoirs to the oily part of the blood, the fat, which ſeems to be depoſited in them, by particular veſſels, continued from the ends of arteries. Theſe cells are of a glandular ſtructure, as Malpighi and others after him have ſuppoſed. The Fat is abſorbed and carried back into the ſyſtem by the lymphatics. The great waſte of it in many diſeaſes, particularly in the conſumption, is a ſufficient proof that ſuch an abſorption takes place.

The fulneſs and ſize of the body, are in a great meaſure proportioned to the quantity of Fat contained in the cells of this Membrane. The *cellulæ adipoſæ* are ſo very ſmall and pellucid, that in lean ſubjects, they are inviſible; but in fat people, they are ſo much diſtended as to fill up the cells of the Cellular Membrane.

The Fat is not confined to the ſurface of the body alone, being met with every where, in the interſtices of muſcles, in the omentum, about the kidnies, at the baſis of the heart, in the orbits, &c.

The chief uſes of the Fat ſeem to be to lubricate all the parts with which it is connected; to facilitate the action of the muſcles; and to add to the beauty of the body, by making it every where ſmooth and equal, and alſo to ſerve as a ſtore houſe of nutritious particles to ſupply the want of food occaſionally, and to nouriſh in certain diſeaſes where a ſufficient quantity of chyle is withheld from the blood.

SECT. VIII.

LIGAMENTS

ARE found almoſt univerſally in the body, and ſerve to connect parts together. Two kinds of Ligamentous fibres are found, one of them elaſtic, and the other inelaſtic.

The Elaſtic Ligament is of a dull yellow colour having no demonſtrable blood veſſels, and very few nerves; therefore has little or no ſenſibility, and is liable to very few diſeaſes. This ſpecies of Ligament is found between the vertebræ, at the brim of the glenoid cavities, connecting the os hyoides to the cranium, and in the coats of arteries, &c. and in great abundance on the necks of grazing animals, where by its elaſticity it aſſiſts greatly in raiſing the head without much muſcular aſſiſtance. It has a ſimilar effect in raiſing the human body when it is bowed down, and thereby ſaves much fatigue, as it acts without any exertion of the animal.

Inelaſtic Ligaments are compoſed of white ſhining pearl, like fibres, being little organized, and having little or no ſenſibility. Of this kind are the capſular Ligaments of the joints, which are made firm, by the fibres rather tearing aſunder, than ſuffering any elongation. And, hence, in all perfect luxations there is a laceration of the capſular Ligament. The tendons are alſo of this kind, connecting the muſcles to the part to be moved.

SECT. IX.

THE NERVES.

The Nerves take their origin from the brain, and ſpinal marrow, are ſtrong white inelaſtic cords, and are each a faſciculus of ſmaller threads, the ſmalleſt fibril of which, is computed to be no more than the 32400th part of a common hair in magnitude; each of theſe fibrils are ſuppoſed to paſs off diſtinctly from their origin in the brain.

The ſwellings or ganglions of the Nerves are not only to be met with at their exit from the ſpine, but likewiſe in various parts of the body. They occur in the nerves of the medulla oblongata, as well as in thoſe of the ſpine. They are commonly of an oblong ſhape, and of a greyiſh colour, ſomewhat inclined to red, which is perhaps owing to their being extremely vaſcular. Internally we are able to diſtinguiſh ſomething like an intermixture of the nervous filaments.

Some writers have conſidered them as ſo many little brains; Lanciſi fancied he had diſcovered muſcular fibres in them, but they are certainly not of an irritable nature; a late writer, Dr. Johnſtone, imagines they are intended to deprive us of the power of the will over certain parts, as the heart, for inſtance; but if this hypotheſis were well founded, we ſhould meet with them only in Nerves leading to involuntary muſcles; whereas it is certain, that the voluntary muſcles receive their Nerves through ganglions. Other theories have been formed concerning them, none of which, however, have as yet led to aſcertain their uſe.

The Nerves, like the blood-veſſels, in their courſe through the body, communicate with each other, and each of theſe communications conſtitutes what is called a Plexus, from whence branches are again detached to different parts of the body. Some of theſe are conſtant and conſiderable enough to be diſtinguiſhed by particular names, as the Semilunar Plexus; the Pulmonary Plexus, the Hepatic, the Cardiac, &c.

That the Nerves are deſtined to convey the principles of motion and ſenſibility to the brain from all parts of the ſyſtem, there can be no doubt; but how theſe effects are produced, no one has ever yet been able to determine. The enquiry has been a conſtant ſource of hypotheſis in all ages, and has produced ſome ingenious ideas, and many erroneous poſitions, but without having hitherto afforded much ſatisfactory information.

Some phyſiologiſts have conſidered a trunk of Nerves as a ſolid chord, capable of being divided into an infinite number of filaments, by means of which the impreſſions of feelings are conveyed to the ſenſorium commune. Others have ſuppoſed them to be an aſſemblage of many ſmall and diſtinct tubes, connected to each other, and thus forming a cylindrical chord, which tubes were ſuppoſed to convey the animal ſpirits from the brain, to every part of the body. They who contend for their being ſolid bodies, are of opinion, that feeling is occaſioned by vibration; ſo that, for inſtance, according to this ſyſtem, by pricking the finger, a vibration would be occaſioned in the Nerve, diſtributed through its ſubſtance, and the effects of this vibration, when extended to the ſenſorium, would be an excital of pain. But the inelaſticity, the ſoftneſs, the connection, and the ſituation of the Nerves, are ſo many proofs, that vibration has no ſhare in the cauſe of feeling.

Others have ſuppoſed that in the brain and ſpinal marrow, a very ſubtile fluid is ſecreted, and from thence conveyed through the imperceptible tubes, which they conſider as exiſting in the Nerves. They have farther ſuppoſed, that this very ſubtile fluid, to which they have given the name of animal ſpirits, is ſecreted in the cortical ſubſtance of the brain and ſpinal marrow, from whence it paſſes through the medullary ſubſtance, but no ſuch fluid can be demonſtrated to exiſt, nor can any cavity be diſcovered in the Nerves.

SECT. X.

ON THE MUSCLES.

THE Muſcles are the organs of motion. The parts that are uſually included under this name conſiſt of diſtinct portions of fleſh, made up of faſciculi of fibres connected together by cellular membranes, and ſo minute that we cannot ſee the ultimate fibre; theſe are ſuſceptible of contraction and relaxation; the motions of which in a natural and healthy ſtate, are ſubject to the will, and for this reaſon they are called Voluntary Muſcles, being ſet into action by a mental ſtimulus. But beſides theſe, there are other parts of the body that owe their power of contraction to their muſcular fibres; thus the heart is of a muſcular texture, forming what is called a hollow Muſcle, and the urinary bladder, ſtomach, inteſtines, &c. are enabled to act upon their contents, merely, becauſe they are provided with muſcular fibres. Theſe are called Involuntary Muſcles, becauſe their motions are not dependent on the will. Theſe are put into action by a mechanical ſtimulus. The Muſcles of reſpiration, being in ſome meaſure influenced by the will, are ſaid to have a mixed motion. The peculiar property which reſides in a muſcular fibre, and fits it to be ſet in action by a certain ſtimulus, is called its irritability, which is dependent upon the nerves.

SECT. XI.

ON THE BONES IN GENERAL.

THE Bones are of a firm and hard ſubſtance, of a white colour, and perfectly inſenſible. They are the moſt compact and ſolid parts of the body, and ſerve for the attachment or ſupport of all the other parts.

Three different ſubſtances are uſually diſtinguiſhed in them; their exterior or Bony part, properly ſo called; their ſpongy cells, and their reticular ſubſtance. The firſt of theſe is formed of many laminæ, or plates, compoſing a firm, hard ſubſtance. The ſpongy or cellular part, is ſo called on account of its reſemblance to a ſponge, from the little cells which compoſe it. This ſubſtance forms almoſt the whole of the extremities of cylindrical Bones. The reticular part is compoſed of fibres, which croſs each other in different directions. This net-work forms the internal ſurface of thoſe Bones, which have cavities.

The flat Bones, as thoſe of the head, are compoſed only of the laminæ and the cellular ſubſtance. This laſt is uſually found in the middle of the Bone dividing it into two plates, and is there called Diploë.

We uſually conſider in a Bone, its body and its extremities. The ancients gave the name of diaphyſis to the body or middle part, and divided the extremities into apophyſis or epiphyſis. An apophyſis, or proceſs, as it is more commonly called, is an eminence continued from the body of the Bone, whereas an epiphyſis is at firſt a ſort of an appendage to the Bone, by means of an intermediate cartilage. Many epiphyſes, which appear as diſtinct Bones in the fœtus, become at length ſo completely united to the body of the Bone, as not to be diſtinguiſhable from it in the adult ſtate. It is not unuſual, however, at the age of eighteen and even twenty years, to find the extremities of Bones ſtill in the ſtate of epiphyſis.

The names given to the proceſſes of Bones, are expreſſive of their ſhape, ſize, or uſe; thus if a proceſs is large, and of a ſpherical form, it is called caput, or head; if the head is flatted, it is termed condyle. Some proceſſes, from their reſemblance to a ſtiletto, a breaſt, or the beak of a crow, are called ſtyliod, maſtoid, or coracoid: others are ſtiled ridges or ſpines. The two proceſſes of the os femoris derive their name of trochanters from their uſe.

A Bone has its cavities as well as proceſſes. Theſe cavities either extend quite through its ſubſtance, or appear only as depreſſions. The former are called foramina or holes, and theſe foramina are ſometimes termed canals or conduits, according to their form and extent. Of the depreſſions, ſome are uſeful in articulation. Theſe are called Cotyloid when they are deep, as is the caſe with the os innominatum, where it receives the head of the os femoris; or Glenoid when they are ſuperficial, as in the ſcapula, where it receives the os humeri. Of the depreſſions that are not deſigned for articulation, thoſe which have ſmall apertures are called ſinuſes; others that are large, and not equally ſurrounded by high brims, are ſtiled foſſæ. Such as are long and narrow, furrows; or if broad and ſuperficial without brims, ſinuoſities.

SECT. XII.

ON THE CONNECTION OF THE BONES.

THE Bones compoſing the ſkeleton are ſo conſtructed, that the end of every Bone is perfectly adapted to the extremity of that with which it is connected; and this connection forms what is called their articulation.

Articulation is divided into Diarthroſis and Synarthroſis, or moveable and immoveable articulation. Each of the two firſt has its ſubdiviſions. Thus the Diarthroſis, or moveable articulation, includes, 1. The Enarthroſis, as it is called, when a large head is admitted into a deep cavity, as in the articulation of the os femoris with the os inominatum. 2. Arthrodia, when a round head is articulated with a ſuperficial cavity, as is the caſe with the os humeri and ſcapula. 3. Ginglimus, or hinge-like articulation, as in the connection of the thigh bone with the tibia. The Enarthroſis and Arthrodia allow of motion to all ſides; the Ginglimus only of flexion and extenſion.

The Synarthroſis, or immoveable articulation, includes, 1. The Suture, when the two bones are indented into each other, as is the caſe with the parietal Bones. 2. Gompoſis, when one Bone is fixed into another, in the manner the teeth are placed in their ſockets.

What is called Symphiſis, is the union of two Bones into one, as in the lower jaw, for inſtance, which in the fœtus conſiſts of two diſtinct Bones, but becomes one in a more advanced age, by the Oſſification of the uniting cartilage.

When Bones are thus joined by the means of cartilages, the union is ſtyled Synchondroſis, when by ligaments, Syneuroſis.

SECT. XIII.

ON THE CARTILAGES.

CARTILAGES are white, ſolid, ſmooth, and elaſtic ſubſtances, between the hardneſs of bones and ligaments, and ſeemingly of a fibrous texture. We are not able to trace any veſſels into their ſubſtance by injection, nor are they ever found tinged in animals that have been fed with madder.

They may be diſtinguiſhed into, 1ſt. Thoſe which are connected with the Bones; and, 2dly, Thoſe which belong to other parts of the body. The firſt ſerve either to cover the ends and cavities of Bones intended for motion, as in the articulations, where by their ſmoothneſs they facilitate motions, which the Bones alone could not execute with ſo much freedom; or they ſerve to unite Bones together, as in the ſymphiſis pubis, or to lengthen them as in the ribs.

Many of them oſſifying as we advance in life, their number is leſs in the adult than in the fœtus, and in courſe there are fewer Bones in the old than in the young ſubject.

Of the ſecond claſs of Cartilages, or thoſe belonging to the ſoft parts, we have inſtances in the larynx, where we find them uſeful in the formation of the voice, and for the attachment of muſcles.

SECT. XIV.

ON THE PERIOSTEUM.

THE Perioſteum is a membrane of a compact inelaſtic texture, reflected from one joint to another, and ſerving as a common covering to the bones, is thickeſt near the joints, and almoſt diſappears in the middle of large bones, and ſeems to be made up of an expanſion of tendons and capſular ligaments; it adheres very firmly to their ſurface, and, by its ſmoothneſs, facilitates the motion of muſcles. It likewiſe ſupports the veſſels that go to be diſtributed through the ſubſtance of the bones, and may ſerve to ſtrengthen the articulations. Where it covers the bones of the ſkull, it has gotten the name of Pericranium.

SECT. XV.

ON THE MARROW.

THE Marrow is a fat, oily ſubſtance, filling the cavities of bones. In the great cavities of long bones it is of a much firmer conſiſtence than in the cells of their ſpongy part. In the former it inclines ſomewhat to a yellowiſh tinge, and is of the conſiſtence of fat; in the latter it is more fluid, and of a red colour. This difference in colour and conſiſtence is owing to accidental cauſes; both kinds are of the ſame nature, and may both be deſcribed under the common name of marrow, though ſome writers give this name only to the fat-like ſubſtance, and call the other the medullary juice.

The Marrow is contained in a very fine and tranſparent membrane, which is ſupplied with a great number of blood-veſſels, chiefly from the perioſteum. This membrana medullaris adheres to the inner ſurface of the bones, and furniſhes an infinite number of minute bags or veſicles for incloſing the Marrow, which is likewiſe ſupported in the cavities of the bones by the long filaments of their reticular ſubſtance.

Beſides the veſſels from the perioſteum, the membrana medullaris is furniſhed with others, which in the long bones may be ſeen paſſing in near the extremities of the bone, and ſending off numerous branches that ramify through all the veſicles of this membrane.

The bones, and the cells containing the Marrow, are likewiſe furniſhed with lymphatics. By their means, the Marrow, like the fat, may be taken up in a greater quantity than it is ſecreted; and hence it is that ſo little is found in the bones of thoſe who die of lingering diſeaſes.

The Marrow was formerly ſuppoſed to be intended for the nouriſhment and renewal of the bones, but this doctirne is now pretty generally and deſervedly exploded. It ſeems probable that the Marrow is to the bones what fat is to the ſoft parts. They both ſerve for ſome important purpoſes in the animal œconomy, but their particular uſe has never yet been clearly aſcertained. The Marrow, from the tranſudation of the oil through the bones of a ſkeleton, is ſuppoſed to diminiſh their brittleneſs; and Havers goes ſo far, as to deſcribe the canals by which it is conveyed through every part of their ſubſtance. But from ſome recent enquiries on this ſubject, I am convinced that theſe pretended canals in a dry bone, are nothing more than the tracts of blood-veſſels, into which, when thoſe veſſels are deſtroyed, the Marrow, which then becomes oily, and burſts from its cells, eaſily inſinuates itſelf, and makes its way through the ſubſtance of the bone to its outer ſurface. There do not ſeem to be any ſuch pores in a freſh bone; and in the living body, the Marrow is not a fluid oil, but a congealed fat incloſed, as we have ſeen, within its proper cell.

SECT. XVI.

ON THE SYNOVIA.

THE ſynovia, which lubricates the ſurfaces of joints, appears to be ſecreted by the inner lamina of the capſular ligament. No glands being demonſtrable, and a ſimilar fluid being found in the thecæ of tendons.

When the Synovia is wanting, or is of too thick a conſiſtence, the joint becomes ſtiff and incapable of flexion or extenſion. This is what is termed anchyloſis.

SECT XVII.

ON THE LIGAMENTS.

LIGAMENTS are white, gliſtening, inelaſtic bands, of a compact ſubſtance, more or leſs broad or thick, and ſerving to connect the bones together. They are diſtinguiſhed by different names, adapted to their different forms and uſes. Thoſe of the joints are called either round or burſal. The round Ligaments are white, tendinous, and inelaſtic. They are ſtrong and flexible, and are found only in the joint of the knee, and in the articulation of the os femoris with the os innominatum. The burſal, or capſular Ligaments, ſurround the whole joint like a purſe, and are to be found in the articulations which allow motion every way, as in the articulation of the arm with the ſcapula.

PART II.

OSTEOLOGY.

SECT. I.

ON THE BONES OF THE SPINE.

THE ſkeleton is commonly divided into head, trunk, and extremities. Trunk and extremities are a better diviſion. The trunk ſhould be firſt underſtood; it is divided into neck, cheſt, loins and pelvis. The cheſt and pelvis have bone all round; in the neck and loins, the only bone is the ſpine.

The ſpine, being the baſis of the trunk, ſhould be firſt ſtudied; it is the pillar of ſupport, ſtraight in a front and back view, in a profile, is bended in different directions; it is formed of two pyramids joined at their baſes, and is made by the juncture of a number of bones called vertebræ.

The vertebræ are divided into two claſſes, true and falſe. True vertebræ are twenty-four in number; theſe form the upper pyramid, the ſeven ſuperior of which, forming the neck, are called cervical; the next twelve, making the back, are called dorſal; and the five inferior, the loins, are called lumbar.

The vertebræ of the neck have, nearly, a perpendicular bearing; thoſe of the back are curved from the fore to the back part; whilſt thoſe of the loins are made to project from the back to the fore part; the whole reſembling the form of an Italic *ſ*.

Of the Spine the uſe is threefold; 1ſt. To ſupport weight; 2dly, For muſcular attachment; and, 3dly, To give lodgement to ſoft parts.

The true vertebræ correſpond with each other in their general characters, tho' each claſs may be diſtinguiſhed by particular marks: each vertebra has a body forming the fore part, and rounded from ſide to ſide; has flat ſurfaces above and below, hard edges; is ſpungy within; has holes for blood veſſels, &c. Poſterior and lateral parts, formed by proceſſes, make a ring. The proceſſes are ſpinal or azygos, on the back part; on the ſides, a pair of tranſverſe or lateral; theſe give convenient attachment to muſcles.

On the upper part, there is a pair of oblique or articulating proceſſes; on the under part, a ſecond pair of oblique proceſſes for articulation. The ſubſtance of the proceſſes is harder than the body of the bone; under each tranſverſe proceſs is a notch; when two vertebræ are joined, this notch forms a hole to admit nerves to paſs through.

The roots of the Spinal proceſſes are rough, for the inſertion of elaſtic ligaments. The holes behind the bodies of the vertebræ, made by the ring of proceſſes on the back part, are ſo oppoſed to each other, that ſthey orm a canal, in which the Spinal marrow is lodged.

Cervical vertebræ have their bodies flat, and not projecting, hollowed from ſide, on the upper part, rounded from ſide to ſide below, mutually receiving and being received. The hole for the Spinal marrow is triangular, the angle behind. Spinal proceſſes are ſhort, in general bifid; tranſverſe proceſſes, ſhort, are perforated to admit the vertebral artery to paſs up to the brain. The articulating proceſſes are very oblique, are covered by articular cartilages, have capſular ligaments, and form joints; the firſt, ſecond, and ſeventh, differ from the reſt.

The ſecond vertebra is called dentata, its body flat on the fore part, Spinal proceſs very ſtrong, bifid, marked by the inſertion of muſcles; its tranſverſe proceſſes ſhort and ſmall. Superior articulating proceſſes, broad, ſtrong, and nearly horizontal; inferior articulating proceſſes more oblique. From the upper part of the body riſes a ſtrong, tooth-like proceſs called odontoid, marked by the attachment of ſtrong ligaments. The atlas differs from the general character; it is a mere ring of bone, the body wanting; the tranſverſe proceſſes are long and perforated; has no ſpinal proceſs; is broad from ſide to ſide; hole round, printed ſtrongly by ligaments, which paſs between it and the tooth-like proceſs of the dentata. The tooth-like proceſs of the dentata tied ſtrongly to the fore part of the atlas, within its bony ring; this ring has a ſmooth ſurface, on which the proceſs plays. The arch of the atlas revolves round the odontoid proceſs, which forms a centre of revolution. The oblique proceſſes above are excavated, forming glenoid cavities, into which the condyles of the os occipitis are received. The inferior oblique proceſſes broad and ſtrong, correſponding with thoſe of the dentata.

The rotary motion of the head is produced by a revolution of the atlas round the dentata. The ſeventh vertebra is very like the dorſal; its Spinal proceſs long, differs from the ſpinal proceſſes of the dorſal, in being rounded at its extremity: this is of uſe in determining muſcular attachment. The other vertebræ colli have nothing particular, except the Spinal proceſſes and bodies becoming larger as they deſcend.

Vertebræ dorſi have their Spinal proceſſes long and drooping one over the other, and have three edges. The length of the Spinal proceſſes encreaſes from the firſt, to the eighth or ninth, and then decreaſes to the laſt. Tranſverſe proceſſes are very long, ſmooth, ſtrong, and a little reclined; the extreme point has a ſmooth ſurface, covered by cartilage, for the articulation of the tubercles of the rib; the articulating proceſſes are nearly perpendicular; the bodies project conſiderably, and are thicker from the fore to the back part, printed by the heads of the ribs on each ſide; have two ſmooth ſurfaces, covered by cartilage, for the articulation of the head of the rib; the head of the rib being received between the bodies of the two vertebræ, each vertebra is imprinted, at its upper and lower edge, by two ribs on each ſide; the hole for the Spinal marrow is ſmaller in the back than in the neck or loins. The firſt and two laſt vertebræ differ from the others: the firſt receives the head of the firſt rib entirely, and part of the ſecond; the two laſt have each one impreſſion for one rib; their tranſverſe proceſſes are ſhort, and without ſurfaces for articulation with the rib.

Lumbar Vertebræ have their bodies large, and are broader from ſide to ſide. The Spinal proceſs is large, broad, and ſtrong, placed nearly horizontal, and not drooping like thoſe of the back; the tranſverſe proceſſes are long, but not ſtrong, the middle one the longeſt. The Articular proceſſes are perpendicular, and the articulation of the laſt vertebra with the ſacrum, the ſame as between each vertebra. The bodies of the vertebræ make the pillar of ſupport, which comes near the centre of the trunk; the proceſſes give convenient attachment to muſcles; the canal, formed by the holes in the vertebræ, contains the ſpinal marrow, from which nerves go off to the different parts of the body. The vertebræ are ſtrongly connected to each other by the intervertebral ſubſtance, which is elaſtic, and of different thickneſs between the bodies of different vertebræ, being thicker below, and gradually becoming thinner as we aſcend.

The Spine may be bended conſiderably forwards and backwards, but laterally, very little. The rotation principally brought out between the atlas and the dentata; the flexion and extenſion of the Spine leſs than is generally imagined, the bones of the pelvis moving on the thigh bones. The centre of gravity of the body rather before the Spine; hence, ſtrong muſcles are neceſſary on the back part. The extenſors are very numerous, and the more ſo, becauſe the lever, with which they act, is ſhort: but the flexors act with a longer lever, as the rectus abdominis.

SECT. II.

ON THE BONES OF THE PELVIS.

The Pelvis, in its general ſhape, reſembles a baſon; when ſtanding on a table the ſides are higheſt; its ridge, called the brim of the Pelvis, divides it into two parts; all that is above the ridge, is the lower part of the cavity of the abdomen; all below the ridge or brim, is properly the cavity of the Pelvis. Being formed in a circle, greater firmneſs is allowed of, with the ſame quantity of bony matter; and this being the centre of motion of the body, great firmneſs was requiſite. Neceſſary that muſcles ſhould have an attachment for motion in all directions; its form is alſo neceſſary for the expulſion of the fœtus, urine and fæces; its axis does not coincide with the axis of the trunk; the trunk is ſupported on the thigh bones; for this reaſon the axis is ſo altered, that the upper part of the ſacrum is in a line with the heads of the thigh bones, and the trunk has a perpendicular bearing on them.

The Pelvis, in a lower view, has three projecting parts, and three notches; theſe, in the freſh ſubject, are formed into two holes by the ſacro-ſciatic ligaments. The Pelvis, in the adult, conſiſts of four bones, os ſacrum, os coccygis, and two oſſa innominata.

The os ſacrum is triangular, in a fore and back view; it is concave before, for the purpoſe of enlarging the cavity of the Pelvis, and convex behind; to its angular point is attached the coccyx, which is directly downwards.

The ſacrum conſiſts of five bones, called falſe vertebræ; the bodies and tranſverſe proceſſes are anchyloſed to each other, ſo as to reſtrain all motion; theſe bones are ſeparable, in the early part of life, form a pyramid, the baſe of which is joined to the laſt vertebra of the loins. The upper part, or firſt bone of the ſacrum, has two articular proceſſes, and a flat ſurface on its body, for articulation with the laſt vertebra lumborum; and has a canal, in which the lower part of the ſpinal marrow is lodged.

The ſpinal proceſſes of the three or four firſt vertebræ, uniting with each other, form a bridge of bone, covering the back part of the canal: from thence to the coccyx, the ſpinal proceſſes are wanting, and the lower part of the ſpinal marrow is covered only by a ſtrong ligamentous membrane.

The ſacrum has four pairs of holes, on the fore and back part; through the poſterior holes paſs very ſmall nervous twigs; through the anterior, paſs the four ſuperior pairs of ſacral nerves; on each ſide of the ſacrum is a rough irregular ſurface, forming a pair of ſhoulders to the bone. The ſacrum is thick above and thin below; irregular, for muſcular attachment, on the back part.

The Os coccygis follows the ſweep of the ſacrum; it conſiſts of four bones, and terminates about an inch from the anus: the firſt bone is broad above, narrow below; and has two lateral proceſſes, making a notch for the fifth ſacral nerve. The other three bones gradually diminiſh in ſize, and are frequently anchyloſed together. The elongation of this bone makes the tail of the quadruped.

The Os Innominatum is of a flat, irregular figure, broad at the upper part, conſiſts of three oſſifications in the young ſubject, to which particular names have been given, viz. ilium, iſchium and pubis; theſe unite to form the acetabulum.

The internal and external ſurfaces of the ilium are covered by muſcles; the ſpine of the ilium, its upper rough edge, its anterior ſuperior, and anterior inferior ſpinous proceſſes, poſterior ſuperior, and poſterior inferior ſpinous proceſſes, are ſharp proceſſes thus ſituated, makes part of the brim of the Pelvis, which has a ſurface for articulation with the ſacrum.

The os pubis makes the anterior part of the Pelvis, and the union of the two forms the ſymphiſis pubis. Its ramus runs downwards, to make a part of the foramen thyroideum; it alſo makes part of the acetabulum.

The ſituation of the iſchium is the bottom of the Pelvis, the ſpinous proceſs of the iſchium, and its tuberoſity, is where the ſacro ſciatic ligaments are attached. It ſends upwards a ramus, which forms a part of the foramen thyroideum, and alſo makes a part of the acetabulum.

The Pelvis of the female is more capacious than that of the male, and the proceſſes at the under part at a greater diſtance.

SECT. III.

THE BONES OF THE THORAX.

THE Thorax, in its ſhape, is different in different people; in general, in well formed perſons, broader from ſide to ſide; in ſome decrepid people, wideſt from the fore to the back part: the bodies of the vertebræ projecting, divide it into two lateral cavities. The Lungs extend behind the ſpine, becauſe the pillar of ſupport being brought nearer to the centre of the body, the cheſt is leſs deep anteriorly than laterally. The Thorax in the freſh ſubject is not ſo large, as it appears to be, on viewing the ſkeleton. The general figure of the Thorax conoid, the apex of the cone being at the upper part.

The Thorax, conſiſts of twelve ribs, on each ſide; of the ſpine, on its back part, the ſternum and zyphoid cartilage on the fore part, and of the cartilaginous appendages of the ribs by which they are attached to the ſternum.

The ribs are divided into two claſſes, true and falſe: ſeven ſuperior on each ſide, called true ribs; five inferior, falſe. Ribs have many things in common; are curved; extend round, but not quite one half ot the body, are placed obliquely; each rib has a head, or poſterior extremity; has two impreſſions made by the two bodies of the vertebræ, to which it is attached; is covered by articular cartilage, and has capſular ligaments attached round its neck. The Tubercle is at a ſmall diſtance from the head of the rib, has two ſurfaces, the ſuperior for the attachment of a ligament; the inferior, covered by articular cartilage, forms a joint with the extreme point of the tranſverſe proceſs of the vertebra. The angle of the rib, where it is moſt bent, forms the poſterior part of the cheſt. Each rib, near the head, is rounded, flattened as it approaches the ſternum; the breadth increaſes; its ſides are ſmooth; edges ſharp; lower edge grooved; the groove becomes ſhallower towards the anterior extremity. Anterior extremity is called ſternal, it is not continued on to the ſternum, but is articulated thereto by a cartilage. The ſternal extremity hollowed, like a cup, in which the cartilage is received. Curve, not truly ſemicircular, moſt bent at the angle; each rib is, as it were, twiſted, conſiſting of two curves not on the ſame plane.

Cartilages; the three ſuperior, nearly ſtraight; the fourth turns, making an angle with the body of the bone, this angle increaſes to the eighth, which is nearly a right one, and then decreaſes. The obliquity of the ribs to the ſpine increaſes, from the firſt to the laſt. The intercoſtal ſpace increaſes from the poſterior to the anterior extremity, like the ſticks of a fan. The diſtance between the angle and head increaſes as we deſcend: in the firſt rib, the angle and tubercle coincide. The diſtance of the bony anterior extremity, from the middle line of the body, increaſes, excepting the ſecond rib. The angle between the rib and cartilage to the eighth rib, becomes more acute, then decreaſes; the length of the rib increaſes to the eighth, and then decreaſes. The crookedneſs decreaſes as we deſcend, the laſt being almoſt ſtraight. The furrow more remarkable to the eighth, then evidently becoming leſs. The motion increaſes from the firſt rib to the laſt.

The ſternum makes the fore part of the Thorax, its general ſhape, oblong; flat on the fore and back part; poſterior flat ſide turned towards the Thorax; the exact form undetermined; different in different ſubjects; its ſituation is oblique with reſpect to the ſpine; is near the ſpine at the upper part, at a greater diſtance below, conſiſts of three bones, theſe are frequently anchyloſed; on its ſides, receives the cartilages of the ſix ſuperior ribs; at the upper part are ſurfaces for articulation with the clavicles; to its lower part is attached the xephoid cartilage.

The Xiphoid Cartilage is frequently bony in old people; in young ſubjects, looſe and moveable; ſhape varies in almoſt every ſubject; ſometimes perforated; ſometimes forked at its extremity.

SECT. IV.

THE BONES OF THE UPPER EXTREMITY.

THE Upper Extremity is divided into ſhoulder or humerus, arm, fore-arm or cubitus, and hand.

The ſhoulder conſiſts of ſcapula and clavicle.

The ſcapula is formed of three oſſifications, ſituated on the ſide of the cheſt, to which it is attached by muſcles, is very moveable; its poſition varies in the action of the arm, being raiſed, depreſſed, brought backwards, forwards, &c.

Its ſhape is triangular, divided into internal and external ſurfaces; external, irregular; internal, more ſmooth and regular; it has three angles, one looks forward and has a glenoid cavity, for the purpoſe of articulation with the os brachii, this called its head, reſembles a head in nothing except having a neck; the other two angles diſtinguiſhed by the terms ſuperior and inferior; the ſides of the triangle, are unequal; upper ſide, called coſta ſuperior ſhorteſt; on the fore-part a proceſs hangs over the ſurface, for the purpoſe of articulation; the inferior looks forwards, downwards and upwards, this called coſta inferior; poſterior ſide looks backwards, called baſis of the ſcapula; the internal ſurface hollowed, has three or four lines made by the tendons of the ſubſcapularis; the external ſurface is divided into two regions, by a proceſs called ſpinal; the extreme part of the proceſs projects over the head of the ſcapula, and is called proceſſus acromion, has ſurfaces for articulation with the clavicle. Proceſſus Coracoides, the extreme part of ſuperior coſta.

The Clavicle; its general form is that of an Italic *ſ*, it is ſituated between the ſternum and ſcapula.

The Scapular Extremity generally higheſt; its two extremities are diſtinguiſhed by the epithets, ſternal and ſcapular: the Sternal extremity is triangular, unequal and irregular; between it and the ſternum is placed an intervening cartilage, which is looſe in the joint, between the cartilages that cover the ſurfaces of the bones; on the under ſide, are rough ſurfaces made by ligaments, which paſs from clavicle, to clavicle; here, alſo, is a ſcabrous ſurface, made by the attachment of a ligament, going to the firſt rib, to which the clavicle is ſtrongly tied; the body of the bone is rounded on the fore part, concave behind, and ſtrongly printed by the attachment of muſcles.

On the concave part is placed the medullary canal. Scapular extremity is large, broad and flat, the poſterior and anterior edges, are printed by muſcles, its extreme point is covered by articulating cartilage, and forms a joint with the proceſſus acromion ſcapulæ; the under ſide is ſtrongly printed by ligaments paſſing from it to the proceſſus coracoides ſcapulæ. The Clavicle is of uſe, to keep the ſcapula at a diſtance from the trunk, and to give greater extent of laternal motion.

Os Brachii, is cylindrical, though irregularly ſo; conſiſts of a head or upper extremity, a body, and a lower extremity; head is rounded; is not placed at the end of the bone, but obliquely; ſo that its axis does not coincide with that of the body of the bone; it is covered by articular cartilage, is adapted to the glenoid cavity of the ſcapula; has a ſhort neck to which the capſular ligament is attached; on the fore part are two tubercles, printed by the inſertion of muſcles; between the tubercles is a groove, in which is lodged the tendon of the long head of the biceps muſcle, the body at its upper part is cylindrical, at its lower part flattened and drawn out into two rough edges, which lead to the condyles.

Condyles forming the lower extremity of the bone, are two rough tuberoſities, for the attachment of muſcles and ligaments; the inner, the longer. The ſurface for articulation with the bones of the fore-arm, with reſpect to the os brachii, is oblique, from ſide to ſide, it conſiſts of three eminences and two cavities, hence plainly ginglymoid, the internal cavity, with two of the ridges, forms a ſurface for articulation with the ulna, called the trochlea; the other ridge is rounded, and on it the head of the radius rotates. On the fore part of the ſurface for articulation is a cavity, into which the coronoid proceſs of the ulna is received, in the flexion of the fore arm. On the back part, is a cavity for the reception of the olecranon, in the extention of the fore arm: in this part the bone is generally diaphanous, and ſometimes worn through.

The fore-arm conſiſts of two bones, radius and ulna; the Radius is ſhorter, and not placed in a line with the os brachii. Radius is external in ſupination; in pronation, partly ſo. The Ulna is priſmatical; at its upper part triangular, at the lower part rounded and ſmall; its upper extremity has two proceſſes, between which is the ſurface for articulation with the os brachii, called the Sigmoid cavity, adapted to the trochlea; the larger proceſs is placed in the axis of the bone, and called Olecranon; to it the tendons of the extenſor muſcles of the fore-arm are attached; on the fore part of the ſigmoid cavity is the ſhorter proceſs called coronoid, printed by the attachment of muſcles and ligament; on the outer ſide is a ſmooth ſurface covered by cartilage, on which the head of the radius rotates; the body of the bone is covered by mnſcles, except the internal and external edges; the internal edge may be diſtinctly felt the whole length of the bone in the living ſubject; to the external edge is attached the interoſſeous ligament, the lower extremity is nearly cylindrical, has a ſurface for articulation with the bones of the carpus; on the inner part is a ſmall ſharp proceſs, called Stiloid, which may be felt in the living body; on the outer part, a ſmooth ſurface receiving the internal part of the lower extremity of the radius.

The Radius, is ſhorter than the ulna, ſmaller above, larger below; its head or upper extremity hollowed to receive the articulating ſurface of the os brachii; the neck is covered by capſular ligament, on the inſide of the head is a ſurface for articulation with the ulna; a little below the head on the inner ſide of the bone, is a large tubertoſity, into which the tendon of the biceps flexor is inſerted, the body of this bone is rounded on the outſide, on the inſide has a thin edge, to which the interoſſeous ligament, is inſerted. The upper part of the radius is covered by muſcles; the lower extremity, large, flattened in the fore part, rounded on the back; the ſurface for articulation a little oblique and oblong; on the inſide, hollowed to receive the lower extremity of the ulna; on the outſide, a proceſs, called ſtiloid, projecting below the ſurface for articulation.

The hand, is divided into three parts, carpus, metacarpus and fingers, comprehending the thumb. The carpus conſiſts of eight bones, laid together like pavement, theſe diſpoſed in two rows, and placed obliquely: the general figure of the carpus, irregular, narrow, before, and hollowed conſiderably, convex, behind, in a fore view, plain; the exterior ſurfaces of all the bones, ſtrongly printed by ligaments paſſing from bone to bone and interſecting each other in different directions; theſe bones diſtinguiſhed by proper names, expreſſive of their general figure. In the firſt row is placed Scaphoides, Os Lunare, Os Cuneiforme, Os Piſciforme; and in the ſecond row, Trapezium, Tarpezoides, Os Magnum, and Os Unciforme.

Metacarpus is meant to expreſs the four bones placed between the carpus and firſt bones of the fingers. The firſt is the longeſt and ſtrongeſt; the ſecond ſhorter than the firſt, the third ſhorter and ſlenderer than the ſecond, the fourth ſhorter than the third, but conſiderably ſtronger; theſe bones agree with each other in their general characters; are rounded on the back part, leſs regular on the inſide, and ſtrongly printed by muſcles. The upper extremity is irregular and articulated with the bones of the carpus; the lower extremity has a rounded head for articulation with the bones of the fingers; the knuckles are formed by this rounded extremity.

The bones of the fingers agree with each other in their general characters, differ from each other only, in their degrees of length and ſtrength; each finger conſiſts of a pyramid of three bones, of which the fire is the longeſt and ſtrongeſt; the ſecond ſhorter, and the third the ſhorteſt, are rounded on the back part, and hallowed within. The upper extremity of the firſt bone, is hollowed to receive the lower extremity of the metacarpal bone; the lower extremity is formed by a pair of condyles, which are received by the upper extremity of the ſecond bone; the lower extremity of the ſecond bone, has alſo a pair of condyles, which are received by the upper extremity of the third bone: on the internal part of the third bone, are two ſcabrous ſurfaces, one, near the upper extremity of the bone, into which the tendon of the flexor muſcle is inſerted; the other forming the lower extremity, to which the ſkin, &c. is firmly connected.

The thumb, like the fingers, conſiſts of a pyramid of three bones: the firſt, at its upper extremity, is articulated with the trapezium, and forms a double ginglymoid, having flexion and extenſion in two oppoſite directions, the lower extremity is rounded, and received into a glenoid cavity, formed in the upper extremity of the ſecond bone; the lower extremity of the ſecond bone has a pair of condyles, which are received in a pair of glenoid cavities, in the upper extremity of the third bone; the third bone, on its inner ſide, has a pair of ſcabrous ſurfaces, which anſwer ſimilar purpoſes to thoſe of the laſt bones of the fingers. The ſides of the extremities of the bones of the fingers and thumb, are ſtrongly printed by the attachment of capſular ligaments.

SECT. XII.

THE BONES OF THE LOWER EXTREMITY.

THE Os Femoris in its general ſhape is cylindrical: it is divided into the body and two extremities: the ſuperior extremity, called head, is attached to the body of the bone by a neck, the head is regularly rounded, in the middle, is a print made by the inſertion of the ligamentum ſuſpenſorium, the lower part of the neck, is marked by the attachment of the capſular ligament; the head and neck are not placed in the axis of the body of the bone, but make an angle with it; this angle differs in different perſons; the upper and outward part of the body of the bone, is formed by a large tuberoſity, called the great trochanter, ſtrongly printed by the inſertion of tendons; on the back part of the bone, between the great trochanter and neck, is a cavity, into which the tendons of many ſmall muſcles are inſerted; below the neck, on the inner and under ſide of the bone, is a leſſer tuberoſity, called the little trochanter, into which the tendons of ſome muſcles are inſerted; the fore part of the body of the femur, is regularly rounded and ſmooth, on the back part is a rough ridge, called linea aſpera; this begins from the ſpace within the two trochanters, and is continued down in the middle of the bone, about two thirds of its whole length; it then divides into two lines, one of which paſſes obliquely to each condyle.

The linea aſpera is made irregular by the attachment of the flexor tendons of the thigh; the lower extremity is conſiderably enlarged, and the articulating ſurface formed into two condyles, the inner one, longer, the external, broader; the ſides of the condyles are ſtrongly printed by the lateral parts of the capſular ligament; on the back part, between the two condyles, is a cavity, into which the crucial ligaments of the joint are inſerted; in the middle of the body of the bone, the medullary canal is placed.

The Leg may be ſaid to conſiſt of three bones, viz. tibia, fibula and petella, the laſt entering into the compoſition, of the joint of the knee. Tibia, an oblong bone of the cylindric claſs; at its upper part, priſmatical, having one edge, and one ſide, internal, which is covered only by common integuments; is divided into a body and and two extremities, which are epiphiſes; the upper extremity is large and called the head, a little below which is a print made by the attachment of the capſular ligament; its upper part formed of two glenoid cavities, adapted to the condyles of the os femoris; between them is a tuberioſity to which he ſemilunar cartilages are attached; behind this tuberoſity is a foſſa, into which the crucial ligaments are inſerted; on the outer ſide of the head of the bone, is a ſmooth ſurface covered by cartilage, to which the upper extremity of the fibula is articulated: about an inch and a half below the head, is a tuberioſity, into which the ligament of the patella is fixed: the poſterior outer edge of the bone, has a ligament attached to it, called interoſſeous, paſſing between it and the fibula; the lower part of the body of the bone, is ſmall and rounded, and is the part uſually injured in fractures; the lower extremity of the bone is irregular; on the internal part, projecting below the ſurface for articulation, is the proceſſus malleolus internus; on the outer ſide is a ſurface, a little hollowed, adapted to receive the lower extremity of the fibula: the ſurface for articulation, is oblong and hollowed from the fore to the back part: round the

lower

lower extremity is a roughneſs, made by the attachments of the capſular ligament; near the upper part of the body of the bone, the medullary canal is placed.

Fibula is a bone of the cylindric claſs; enlarged at its extremities; not given for the purpoſe of ſupporting weight, or increaſing the variety of motion, but for the convenient attachment of muſcles; its upper extremity is called head, is articulated with the head of the tibia on the outſide, but forms no part of the joint of the knee; the lower extremity is articulated with the inferior extremity of the tibia, projecting conſiderably below the ſurface for articulation, ſtrengthens the joint of the foot, and is called malleolus externus; its inner ſide is ſmooth, printed by cartilage; on it the outer part of the aſtragalus plays; the body of the bone is irregular, every where covered by the attachment of muſcles; to its inner edge the interoſſeous ligament is inſerted; the upper part of the body is ſmalleſt and moſt liable to fracture.

The patella, on the external part, is nearly triangular; one angle being turned downwards, is called its apex; to it the ligament of the patella is attached, by means of which, this bone is firmly connected with the tibia; to the upper part, called baſis, is attached the common tendon of the extenſor muſcles of the leg; its inner ſide is divided into two oblong ſurfaces by a ridge: theſe ſurfaces are adapted to the condyles of the os femoris, on which the patella plays in the different motions of the knee.

The Foot differs from the hand, in being joined to the leg at right angles, is ſtronger, being adapted to ſupport the weight of the whole body; is arched on the under part, by which the weight of the body is thrown on three points. The foot is divided into tarſus, metatarſus and toes. The Tarſus conſiſts of ſeven bones. 1ſt. Os Calcis, of a cuboid figure, has ſix ſides, forms the projecting part of the heel, on the inſide, is hollowed, forming a part of the calcaneum, is ſtrongly marked by the attachment of tendons and ligaments, has two ſurfaces for articulation, with the aſtragalus, has one ſurface for articulation, with the os cuboides. 2d. Aſtragalus placed on the centre of the arch, above is rounded from the fore to the back part, forming a ſurface for articulation with the bones of the leg, the outer ſide has a ſurface, which moves on the internal part of the lower extremity of the fibula, on the inſide, another ſmooth ſurface for motion on the malleolus internus, on the under part are two ſurfaces for articulation, with the os calcis, on the fore part is a rounded head for its articulation, with os naviculare.

3d. Naviculare, hollowed on the back part to receive the head of the aſtragalus, on the fore part, is articulared with the three cuneiform bones.

The 4th, 5th and 6th, called Oſſa Cuneiformia; that on the inſide of the foot, called cuneiforme internum, is articulated with a part of the os naviculare on the back part, and on the fore part with the firſt bone of the great toe; the next, os cuneiforme medium is, on the back part, articulated with the os naviculare, on the fore part with the metatarſal bone of the ſecond toe, ou the inſide with the cuneiforme internum, and on the outſide with the cuneiforme externum; the third, cuneiforme externum, is articulated, on the back part, with os naviculare, on the fore part, with the metatarſal bone of the third toe; on the inſide, with the os cuneiforme medium, and on the outſide, with a part of the os cuboides.

7th, Os cuboides articulated, on the back part, with the os calcis, on the fore part, with the metatarſal bones of fourth and fifth toes, on the inſide, with the cuneiforme externum, on the outer ſide, is a furrow, in which the tendon of the peroneus longus is lodged.

Note, the exterior ſurfaces of theſe bones, like thoſe of the carpus, are every where deeply printed by the inſertion of ligaments paſſing from bone to bone, and interſecting each other in a variety of different directions.

Metatarſus conſiſts of four bones like thoſe of the carpus; that which ſuſtains the ſecond toe, the longeſt; that ſuſtaining the little one, the ſhorteſt and ſtrongeſt. The bones of the toes ſo exactly correſpond with thoſe of the fingers and thumb, that they need no particular deſcription.

SECT. XIII.

THE BONES OF THE HEAD.

THE head conſiſts of a number of bones, part of which form the cranium or brain-caſe, the others form the face, in which we include the upper and lower jaw, teeth, &c. the whole making an irregular piece of mechaniſm. In a ſide view, the head is formed of two ovals, which joined, make the whole a ſhort ſpheroidal triangle.

The Cranium, when ſeparated from the bones of the face, is of an ovi-form figure; the ſmaller extremity forming the fore-head, the larger, the hind-head; it is placed obliquely, the axis looking upwards and forwards; the under part is irregular and called baſis of the ſkull; the upper part is convex, in general ſmooth, excepting five projecting parts, which point out the parts of the bones that were firſt oſſified; the anterior part is called ſinciput; the ſuperior middle part, vertex; the poſterior part, occiput, or hind-head; the lateral parts, temples.

The Cranium is formed of eight bones, one frontal, two parietal, one occipital, two temporal, the os ethmoides, and os ſphenoides; the ſix former of which are proper to the ſkull, the two latter common to it and the face; theſe bones are united to each other by ſutures; the firſt, connecting the os frontis on the back part to the two parietal bones tranſverſely, is called coronal; in the upper middle line of the ſkull, paſſing from the occipital bone behind the os frontis on the fore part, and uniting the two parietal bones, is the ſagittal ſuture.

Note, This ſuture is ſometimes contained through the middle of the os frontis to the noſe.

On the back part is the lambdoidal ſuture, articulating the ſuperior part of the os occipitis to the poſterior parts of the parietal bones; from the lower part of the leg of the lambdoidal ſuture, paſſing tranſverſely to the ſquamoſe part of the temporal bone, is the additamentum ſuturæ lambdoidalis, connecting the petrous portion of the temporal bone to the poſterior inferior angle of the parietal bone.

The upper thin part of the temporal bone, is called ſquamoſe, is articulated to the lower part of the parietal bone by the ſquamoſe, or falſe ſuture. The bones of the cranium are joined to thoſe of the face by a ſuture, called tranſverſe. The upper part is regularly rounded; its ſides are flattened, forming the temporal foſſæ; the under part very irregular, printed by muſcular attachment, perforated in many parts to admit blood veſſels, nerves, &c. to enter into and paſs from the cavity of the ſkull.

General appearance of the internal part of the ſkull in a ſide view; the ſuperior part pretty regular; the internal table of the ſkull furrowed by the artery of the dura mater; the larger branches running in the diagonal line of the parietal bone, marked by the convolutions of the brain; in the ſuperior middle line, marked by the longitudinal ſinus, oppoſite the tranſverſe occipital ridge, furrowed by the lateral ſinus; at the lower part, or internal baſis, is very irregular, divided into three regions, which correſpond with the irregularities in the baſis of the brain.

The baſis of the ſkull, externally, may be divided into three regions, the anterior being all that part before the pterygoid proceſſes of the ſphenoidal bone; the ſecond region, that part contained between the boundaries of the anterior, included within a line drawn through the maſtoid proceſſes of the temporal bones; the poſterior extends from the extreme part of the middle region to the tranſverſe occipital ridge; the anterior region has the ethmoidal bone placed in the middle, and the ſuperior parts of the orbits on each ſide; behind the ethmoidal bone is a part of the body of the ſphenoidal bone; the lateral boundaries of this region are formed by the lateral proceſſes of the os ſphenoides. The foramina, beginning from the fore part, are found in the following order: in the orbiter ridge of the os frontis, foramen orbitale externum ſuperius, through which paſſes the opthalmic branch of the fifth pair of nerves; on the inner ſide of the orbit, between the orbiter plate of the os frontis and the orbiter plate of the os ethmoides, called os planum, the foramen orbitale internum anterius, through which paſſes the naſal twig of the opthalmic branch of the fifth pair of nerves; on the outer ſide of the orbit, foramen orbitale internum exterius in the lateral proceſs of the ſphenoidal bone; at the poſterior part of the orbit, foramen opticum, through which the optic nerve and artery paſs; immediately behind this, foramem lacerum orbitale ſuperius, through it paſs the third and the fourth pair, the firſt branch of the fifth and the ſixth pair of nerves; above the foramen lacerum, is the foramen rotundum; through it the ſecond branch of the fifth pair paſſes; on the fore part of the pterygoid proceſs, foramen ſphenopterigoideum: the centre of the middle region is formed by a part of the os occipitis; the pterygoid proceſſes of the ſphenoidal bone, riſing on each ſide of the body of the os ſphonoids, point out the boundaries of the noſe.

Each proceſs divided into two alæ, called ala pterygoidea interna and externa, between which is the foſſa pterygoidea, on the point of the ala pterygoidea interna is placed an unciform proceſs, round which, the tendon of the circumflexus palati plays; the lateral parts are formed by the petrous portions of the temporal bones; in each temporal bone is a glenoid cavity, in which the condyles of the lower jaw are received; before each is a proceſs, called zygomaticus; on the poſterior part of the cuneiform proceſs of the occipital bone, the condyles of the os occipitis are placed, behind the pterigoid proceſs, the foramen ovale, through which the third branch of the fifth pair of nerves paſſes; behind this, formen ſpinoſum, through which the artery of the dura mater enters the ſkull; between the extreme part of the petrous portion of the temporal bone, and the cuneiform proceſs of the os occiptis, is a hole, which in the freſh ſubject is filled with cartilage; in the petrous portion of the temporal bone is a ſpiral canal for the caroted artery: behind this is the thimble-like cavity, through which the jugular vein paſſes; on the outſide of it, a proceſs, called vaginal, into which is placed a proceſs, called ſtiliform; between the ſtiliform and maſtoid proceſſes, is the foramen ſtilomaſtoideum, through it paſſes the portio dura of the auditory nerve; between the zygomatic and maſtoid proceſſes, on the outſide, is the meatus auditorius externus; under the condyles of the os occipitis, a pair of holes for the paſſage of the ninth pair of nerves; the poſterior region is principally formed by the inferior part of the os occipitis; on its anterior part, is the foramen magnum occipitale; on the lateral parts of the foramen magnum are ſmall holes, which allow veins to paſs through them; the back part of the poſterior region is every where printed by the inſertion of muſcles.

The internal baſis of the ſkull, like the external, is irregular, and may be divided into three regions; the anterior region, being all that part placed between the anterior clinoid proceſſes of the ſphenoidal bone; in the anterior middle part is the cribriform plate of the ethmoidal bone, in the middle of which ariſes a perpendicular proceſs, being part of the perpendicular plate of the ethmoidal bone, called criſta galli; the poſterior, made by part of the body of the ſphenoidal bone, and the ſides formed by the internal parts of the orbiter proceſſes of the os frontis. This region is occupied by the anterior lobes cerebri.

The middle region is all that part extending from the boundaries of the anterior region, to the ſpine of the petrous portion of the temporal bone behind; the middle part is formed by the body of the ſphenoidal bone; in its centre is a cavity, called ſella turcica, in which the pituitary glandule is lodged; this ſurrounded by four proceſſes, called clinoid, two anterior, two poſterior, the lateral parts are made by a pair of deep cavities, formed partly by the lateral proceſſes of the ſphenoidal bone and the internal parts of the temporal bones; in theſe lateral cavities, the middle lobes cerebri are lodged.

The poſterior region is large and more regular in its form, comprehending all the parts within the ſpine of the petrous portion of the temporal bone, and the internal tranſverſe occiptal ridge; the middle fore part is formed by the cuneiform proceſs of the os occipitis, behind which, is the foramen magnum occipitale; the back part is ſubdivided into two cavities, by the perpendicular ſpine of the os occipitis; in theſe cavities, the two lobes of the cerebellum are placed; on the anterior lateral part is a hole leading into the petrous portion of the temporal bone, called foramen auditivum, through it the auditory nerve paſſes. A little below, a foramen for the jugular vein and par vagum; in the middle, the foramen magnum occipitale for the ſpinal marrow and vertebral arteries; on the upper part, over the foramen magnum, is a pair of holes for the ninth pair of nerves.

The os frontis in its general ſhape reſembles a ſcollop ſhell, originally formed of two oſſifications; theſe commonly unite, and before the time of puberty, the ſuture is obliterated, it then making but one bone; in ſome inſtances, the ſuture remains open throughout life; the outer part pretty regularly rounded, has two projecting parts, where oſſification firſt began; the outer edge ſerrated, forming the coronal ſuture; the anterior middle part projects conſiderably, made irregular by the articulation of the oſſa naſi; on each ſide arched, forming the ſuperior orbiter ridges; the extreme parts of each orbiter ridges are articulated with the os malæ; the lateral part of the bone forming a portion of the temporal foſſa, articulated with the lateral proceſs of the ſphenoidal bone; beneath the orbiter ridges, a pair of broad proceſſes, which form the ſuperior parts of the orbits; between theſe proceſſes the ethmoidal bone is articulated; at the lower anterior part of the bone, the bony plates are at a diſtance from each other, forming a cavity, called frontal ſinus: the internal part, printed by the convolutions of the brain; in the middle line, divided into two lateral cavities by a proceſs, called ſpine of the os frontis; this, as it recedes from the fore part, is furrowed, and gives lodgment to the anterior portion of the longitudinal ſinus; to it, the falciform proceſs of the dura mater is attached.

The parietal bones are two in number, convex on the outer part, concave within; each bone of a quadrilateral figure, conſiſting of four ſides and four angles; the angles are diſtinguiſhed by anterior ſuperior, anterior inferior, poſterior ſuperior, and poſterior inferior: the anterior ſide, ſerrated, and articulated with the back part of the os frontis, forming one half of the coronal ſuture; the upper ſide, ſerrated, and articulated with its fellow, making the ſagittal ſuture; the poſterior ſide, articulated with one half of the occipital bone, making a part of the lambdoidal ſuture; the inferior ſide, near the anterior inferior angle, articulated with a ſmall part of the lateral proceſs of the ſphenoidal bone; the middle part, articulated with the ſquamoſe portion of the temporal bone, forming the ſquamoſe ſuture; the poſterior inferior angle, being articulated with the maſtoid proceſs of the temporal bone, forms the additamentum ſuturæ lambdoidalis; the internal part of the bone, furrowed in a diagonal line by the artery of the dury mater, the larger branches running from the anterior inferior, to the poſterior ſuperior angle; on the upper ſide, near the ſuperior poſterior angle, a ſmall hole, which admits an artery to paſs from the external parts to the dura mater. Os occipitis, a quadrilateral figure; the upper part is externally, ſmooth and regular, articulated with the two parietal bones, forming the lambdoidal ſuture; below, irregular, and printed by the inſertion of the extenſor-muſcles of the head; in it are the foramen magnum occipitale, the condyles of the os occipitis, and on the fore part the cuneiform proceſs; the lateral parts, articulated with the petrous portions of the temporal bones; the cuneiform proceſs, on the fort part, articulated with the back part of the body of the ſphenoidal bone; under each condyle, a hole for the paſſage of the ninth pair of nerves; on the back part of the condyles, a pair of holes which tranſmit veins; the internal part of the bone divided into four cavities, by a crucial ſpine; to the upper part of the perpendicular limb, is attached the poſterior portion of the falciform proceſs of the dura mater, being alſo furrowed by the longitudinal ſinus; the tranſverſe limb is oppoſite to the tranſverſe occipital ridge, and furrowed by the lateral ſinuſes; to this limb are attached the lateral proceſſes of the dura mater, forming the Tentorium cerebello ſuper expanſum; the inferior part of the perpendicular limb gives attachment to a proceſs of the dura mater, dividing the two lobes of the cerebellum; the internal part of the cuneiform proceſs, hollowed, and gives lodgment to the medulla oblongata.

Os temporis; one on each ſide; is divided into two parts, a ſuperior thin part, called the ſquamoſe portion; an inferior thick irregular one, called the petrous portion; the ſquamoſe portion has an oblique ſurface for articulation, with the lower ſide of the parietal bone, on the back part; and with the lateral proceſs of the ſphenoidal bone, on the fore part; the external ſurface of the ſquamoſe portion gives attachment to a part of the temporal muſcle, and forms the inferior poſterior part of the temporal foſſa; from the ſquamoſe portion ariſes a proceſs, called proceſſus zygomaticus, which, running forwards, is articulated with the os malæ; on the under part of the zygomatic proceſs, a glenoid cavity, into which the condyle of the lower jaw is received; on the fore part of this cavity, an eminence, called tuberoſity of the maxilla ſuperior. The petrous portion irregular, in it the organ of hearing is contained; the external poſterior part is articulated with the os occipitis; on the fore part of the maſtoid proceſs, is the meatus auditorius externus; on the under ſide, the vaginal proceſs, in which, the ſtiliform proceſs is placed; between the ſtiliform and maſtoid proceſſes, foramen ſtilomaſtoideum; before the ſtiliform proceſs, the ſpiral canal for the caroted artery; on the anterior point of the petrous portion, meatus auditorius internus; on the internal ſide, the ſquamoſe portion, marked by the convolutions of the brain; the petrous portion has a ſpine, to which the tranſverſe proceſs of the dura mater is attached, and below which, is the foramen auditivum.

Os Ethmoides, a four-ſided figure, placed between the orbiter proceſſes of the os frontis, dividing the two orbits from each other; the larger part of this bone enters into the compoſition of the noſe; the ſuperior part is perforated by a number of ſmall holes; hence called cribriform plate of the ethmoid; this is the only part of the bone ſeen in the baſis of the ſkull; the whole bone is ſub-divided into two lateral parts by a perpendicular plate, forming the upper portion of the ſeptum narium, and being continued through the cribriform plate, makes the criſta galli, to which the falciform proceſs of the dura mater is attached; on each ſide is a ſmooth bony plate, called os planum, forming the inner ſide of each orbit; between the os planum and the perpendicular plate, on either ſide, an irregular ſpungy bone is hung out, covered by Schnider's membrane, called os turbinatum ſuperius; between the os turbinatum ſuperius and os panum, is a number of ſmall cells, called cells of the ethmoid; theſe ſubdivided by very thin bony plates, called oſſa papyracea.

The os ſphenoides is placed in the baſis of the ſkull, like a wedge; on the anterior part, articulated with the orbiter proceſſes of the os frontis; laterally to the inferior anterior part of the os frontis, to the os malæ and os temporis; the middle anterior part to the cribriform plate of the os ethmoides; and the back part to the cuneiform proceſs of the os occipitis. In an internal view, may be divided into a body and two lateral proceſſes; the body is ſurrounded by four proceſſes, called clinoid, between which is the ſella turcica; in the lateral proceſſes are cavities giving lodgment to the middle lobes cerebri; under each anterior clinoid proceſs, foramen opticum; between the anterior clinoid and lateral proceſſes, foramina lacera orbitalia ſuperiora; behind theſe, foramina rotunda; a little further back, foramina ovalia; and in the poſterior points of the lateral proceſſes, the foramina ſpinoſa; in a front view, the lateral proceſſes form the external parts of the orbits; the body of the bone divided into two cavities, by a perpendicular plate; theſe are called ſphenoidal ſinuſes; below, the anterior parts of the pterygoid proceſſes; in a back view, the ſurface for articulation with the cuneiform proceſs of the os occipitis; on each ſide of the body is, foramen ſphenoptery goideum; at the lower part, and on the under ſide of the pterygoid proceſſes, are the alæ pterygoidæ, ariſing from the lateral parts of the bone; thoſe on the back part are ſubdivided into two proceſſes, called ala externa and ala interna, between which is the foſſa pterygoidea; on the ala interna is an unciform proceſs, round which the tendon of the circumflexus palati plays; the lateral parts complete the temporal foſſæ.

SECT. XIV.

ON THE BONES OF THE FACE.

THE Bones of the Face, beſides the lower jaw and teeth, are thirteen in number, viz. ſix pairs and one azygos. The Bones of the Face and Noſe, are united to thoſe of the ſkull by the tranſverſe ſuture.

Published as the Act directs by C. Cooke, No. 17, Paternoster Row, Jan.y 9th 1789.

C. Warren sc.

The Oſſa Naſi are two in number, convex on the outer part, and hollowed within; at the upper part of the noſe they are articulated to the middle part of the os frontis by the tranſverſe ſuture; in the middle line of the Face, to each other by a proper ſuture; laterally, to the naſal proceſſes of the maxillary bones; and, at the lower part, to the cartilaginous part of the noſe; near the middle of each bone is generally a foramen, that admits of an artery to paſs through it.

The Os Malæ is of a four-ſided figure, having four ſides and four angles.

The ſuperior part is articulated with the outer part of the orbiter brim of the os frontis; poſteriorly, with the zygomatic proceſs of the temporal bone, forming the zygoma, anteriorly, with the outer part of the maxilla ſuperior, and forms the outer part of the orbit; between, the lateral proceſs of the ſphenoidal bone, and the orbiter proceſs of the maxilla ſuperior, is the foramen lacerum orbitale inferius; on the outer part of the bone is a ſmall hole, which admits of an artery and vein to enter, and of a nerve to come from the orbit.

The Os Maxillare Superius, is a bone of an irregular figure on the outer ſide, a little hollowed on the fore part, to which muſcles are attached.

On the back part it is rounded, forming the tuberoſity of the upper jaw; above is a ſurface for articulation with the os malæ, on the fore part of which is the foramen orbitale externum inferius; the upper part is drawn out into two proceſſes; the anterior, called naſal, is at its upper part articulated by the tranſverſe ſuture to the os frontis; on the inſide it is grooved, forming the ductus ad naſum; the poſterior proceſs, called orbiter, is ſmooth, and forms the lower part of the orbit; the internal part of the body of the bone is hollow, forming the Antrum Highmorianum: on the inſide irregular, forming a part of the noſe; it has an horizontal proceſs, called palatine, by which it is articulated with its fellow; this proceſs forms the anterior part of the roof of the mouth; behind the palatine proceſs is a ſurface for articulation with the os palati; on the under part are the alveoli, in which the teeth are placed.

The Os Unguis is of a four-ſided figure, extremely thin; it is grooved on the fore part to give lodgment to a part of the ſaccius lacrymalis; is articulated above with the arbiter proceſs of the os frontis; behind, with the os planum; below, with the orbiter proceſs of the maxilla ſuperior; and before, with the naſal proceſs of the maxillary bone.

The Os Palati, a bone of an irregular figure, has a proceſs which forms the back part of the palate: it is articulated with the palatine proceſs of the maxilla ſuperior on the fore part, and to its fellow on the oppoſite ſide, and has a proceſs articulated to the poſterior part of the upper jaw; behind is articulated to the fore part of the pterygoid proceſs of the ſphenoidal bone; a ſmall portion of this bone comes into the orbit; between the pterygoid proceſs, and the inferior proceſs of this bone, is a hole, called foramen ſphenopalatinum, and, in the palatine proceſs, the foramen palatinum.

The Os Turbinatum Inferius, is an irregular ſpungy bone hung out in the cavity of the noſe, covered by Schneider's membrane, articulated to the internal part of the maxillary bone; under it is the opening of the ductus ad naſum.

The Vomer forms the poſterior part of the ſeptum narium; behind it is articulated with the middle lower part of the body of the ſphenoidal bone; before, with the perpendicular plate of the ethmoid; beneath, with the palatine proceſſes of the maxillary bone, and with the oſſa palati.

The Lower Jaw, in its general figure like the conſonant V, originally formed of two oſſifications, united on the fore part, and called ſymphiſes, is every where printed by the attachment of muſcles; the under part is called baſis; from it ariſes, at right angles, a broad proceſs for articulation; the poſterior part of the baſis is called the angle; the proceſs of the jaw is ſubdivided into two leſſer proceſſes; the poſterior one is formed into a condyle for articulation with the glenoid cavity of the temporal bone; the other drawn into a thin ſpine, called coronoid; on the upper part are the alveolar proceſſes, in which the teeth are placed; on the internal part of the proceſs of the jaw, is a hole which admits of an artery, vein and nerve, to ſupply the parts of the jaw and teeth; this canal opens on the fore part, near the ſymphiſis.

The Teeth, in the adult ſubject, are thirty-two in number; ſixteen in each jaw. Theſe being in pairs, in order to underſtand them, we need only examine one ſide of the jaw. Teeth are are divided into the following claſſes: the two anterior are called inciſores; the third, cuſpidatus; the fourth and fifth, bicuſpides; and the three laſt, molares. Each tooth is divided into baſis, body, neck and phang: each tooth has a cavity, correſponding with its general figure; the cavity lined with a vaſcular membrane, on which the nerves of the teeth are ſpread out.

The firſt ſet generally make their appearance about the 6th month, are twenty in number, and begin to fall about the 6th or 7th year.

The Plate of DISEASED SCULLS having been referred to ANATOMY, but coming with greater Propriety under SURGERY, the Reader will find an Explanation of the Plate in that Syſtem.

Explanation to the PLATE *of* OSTEOLOGY.

FIGURE I.

A front View of the Human Skeleton, with ſome of the Ligaments and Cartilages, which connect the Bones to each other.

HEAD AND NECK.

a, Os frontis. *b*, Os parietale. Between *a* and *b*, part of the coronal ſuture.

c, The pars ſquamoſa of the temporal bone. Between *b* and *c* the ſquamous ſuture. Below the pars ſquamoſa, the zygoma; and lower down, above *f*, the maſtoid proceſs. Between the pars ſquamoſa and the cavity, which contains the eye-ball, called orbit, the temporal proceſs of the ſphenoid bone is ſeen.

d, Os malae. Above *d*, a portion of the tranſverſe ſuture.

e, Os maxillare ſuperius, with the eight teeth of the right ſide. The naſal proceſs of ſuperior maxillary bone has the os naſi, joined by the lateral naſal ſuture, to its inſide, and at the outſide, within the orbit, the os unguis. The oſſa naſi joined to each other before, by the anterior naſal ſuture.

f, Os maxillare inferius with ſixteen teeth; the four anterior named inciſores, the two corner ones canini, and the five poſterior on each ſide, molares. Oppoſite to *f*, the angle of the lower jaw, above *f*, the condyloid proceſs, by which the jaw is connected to the temporal bone, at the root of the zygoma; and behind the os malae, the coronoid proceſs.

g, The ſeven cervical vertebræ, with their intermediate cartilages. Oppoſite to *g*, their tranſverſe proceſſes.

TRUNK.

a, Sternum. *a*, Its middle piece, to which one half of the cartilage that connects the ſecond rib, the whole of the cartilages of the third, fourth, fifth, ſixth, and one half of the ſeventh, are fixed. Above *a*, the firſt or upper triangular piece, to which the clavicle, and one half of the cartilage that connects the ſecond rib, are fixed. Below *a*, the extremity, or third piece of the ſternum, named cartilago enſiformis, to which one half of the cartilage that connects the ſeventh rib, is fixed.

b, The ſeventh, or laſt true rib.

c, The twelfth, or laſt of the five falſe ribs.

d, The five lumbar vertebræ, with their intermediate cartilages. Oppoſite to *d*, their tranſverſe proceſſes.

e, The os ſacrum, with its five diviſions.

f, Os innominatum, divided into, *g*, Os ilium. *h*, Os pubis.

i, Os iſchium. Oppoſite to *i*, the foramen thyroideum.

SUPERIOR EXTREMITY.

a, The clavicle fixed before, to the firſt piece of the ſternum, and outwards to the acromion of the ſcapula.

b, The ſcapula. Above *b*, the cervix of the ſcapula. Oppoſite to it, the inferior coſta; and below the outward extremity of the clavicle, the ſuperior coſta, and coracoid proceſs, are ſeen.

c, The os humeri. The upper end of it, which is connected to the cavity of the ſcapula, named glenoid, below the acromion, is named its head or ball; on each ſide of which is ſeen a tubercle, named external and internal, and between theſe, a groove for lodging the long head of the biceps flexor cubiti.

d, The internal condyle.

e, The external condyle. Between *d* and *e*, the trochlea, upon which the ulna moves.

f, The radius. The upper end, which moves on the external condyle of the os humeri, is named its head; below that, the tubercle for the inſertion of the biceps flexor cubiti, and between theſe the cervix. The inferior end of it is connected to the carpus.

g, Ulna. The upper end of it forms the coronoid proceſs, for the inſertion of the brachialis muſcle. The inferior end has a proceſs, named ſtyloid, which is connected to the carpus by a ligament.

h, The carpus, formed of eight bones.

i, The metacarpal bone of the thumb.

k, The metacarpal bones of the four fingers.

l, The two joints of the thumb.

m, The three joints or phalanges of the fore-finger; and the ſame are ſeen in each of the other three.

INFERIOR EXTREMITY.

a, The os femoris. The upper end of it is named its head or ball, which is lodged in a deep ſocket of the os innominatu, named acetabulum. Between the head and trochanter major, the cervix.

b, Trochanter major. *c*, Trochanter minor.

d, Internal condyle. *e*, External condyle.

f, Patella. The place where it moves upon the os femoris, is named trochlea.

g, Tibia. Between the tibia and the condyles of the os femoris, the ſemilunar cartilages are ſeen; and below the joint, the tubercle of the tibia.

h, Fibula. *i*, Malleolus internus. *k*, Malleolus externus.

l, Os calcis. Between *l* and *m*, the other ſix bones of the tarſus.

m, The metatarſal bones of the four toes.

n, The three joints, or phalanges of the four toes.

o, The metatarſal bone of the toe.

p, The two joints of the great toe.

FIGURE II.

A Back View of the Human Skeleton, with ſome of the Ligaments and Cartilages which connect the Bones.

HEAD AND NECK.

a, Os parietale, joined to its fellow by the ſagittal ſuture.

b, The os occipitis, joined to the parietal bones by the lamdoid ſuture, which is between *a* and *b*. *c*, Os malae.

d, Maxilla inferior, with a view of the teeth of both jaws from behind. *e*, The ſeven cervical vertebræ.

TRUNK.

a, The ſeventh, or laſt true rib. *b*, The twelfth, or laſt rib.

c, The five lumbar vertebræ. *d*, Os ſacrum. *e*, Os Cocygis.

f, Os innominatum, divided into, *g*, Os ilium.

h, Os pubis. *i*, Os iſchium.

SUPERIOR EXTREMITY.

a, The clavicle, joined outwards to the acromion of the ſcapula.

b, The ſcapula. *c*, Os humeri. *d*, Internal condyle.

e, External condyle. *f*, Radius. *g*, Ulna, its upper end, named Olecranon; and near the wriſt, its ſtyloid proceſs.

h, The eight bones of the carpus.

i, The metatarſal bone of the thumb.

k, The metatarſal bones of the four fingers.

l, The two joints of the thumb.

m, The three joints, or phalanges of the four fingers.

INFERIOR EXTREMITY.

a, Os femoris. *b*, Trochanter major, and at the inſide of it, the cervix. *c*, Trochanter minor. *d*, Internal condyle.

e, External condyle. *f*, Tibia. *g*, Fibula.

h, Malleolus internus. *i*, Malleolus externus.

k, The ſeven bones of the tarſus. *l*, The metatarſus.

m, The joints or phalanges of the toes.

FIGURE III.

Is a Skeleton of an adult put into this poſture to ſhew it in a greater ſcale. I thought better not to figure it, the bones being explained in *fig*. 1, and 2, the deſign of this figure being to ſhew the ſkeleton, without being defaced with references.

FIGURE IV.

The under ſide of the firſt vertebra of the neck.

FIGURE V.

A ſide view of the ſecond vertebra.

FIGURE VI.

a, The proceſſus dentatus of the ſecond vertebra.

b, The under ſide of the oblique proceſs.

c, The ſpinal proceſs.

FIGURE VII.

a, The under ſide of the body of the ſeventh vertebra of the neck. *b*, The tranſverſe proceſſes. *c*, The oblique proceſſes.

d, The ſpinal proceſs.

FIGURE VIII.

a, The ſpinal proceſs of the ſecond vertebra of the back.

b, The under and fore ſide of the body of the vertebra.

c, The tranſverſe proceſſes.

FIGURE IX.

a, The upper oblique proceſſes of the third vertebra of the back.

b, The tranſverſe proceſſes. *c*, The ſpinal proceſs.

FIGURE X.

a, The body of the third vertebra of the loins.

b, The tranſverſe proceſſes.

c, The upper oblique proceſſes.

d, The ſpinal proceſs.

FIGURE XI.

The foreſide of the os ſacrum.

1, 2, 3, 4, 5, 6, are parts of the os ſacrum, which, in young ſubjects, are diſtinct bones.

A, Part of the os ſacrum, which articulate with the ſpongy body of the loweſt vertebra of the loins.

B, B, Two proceſſes of the os ſacrum, which articulate with the inferior oblique proceſs of the laſt vertebra of the loins.

C C, The channel through which the medulla ſpinalis paſſes,

PART III.

ON MYOLOGY.

MUSCLES are generally oblong, going from one bone to another. And each extremity has tendinous fibres, which commonly run in the direction of the muſcle, but are ſometimes reverſed. Tendons are to muſcles, what ligaments are to bone; but ſome muſcles are without tendons. The tendinous fibre, is not a continuation of the muſcular fibre. The uſe of tendons, are to connect muſcle to bone, tendons are made ſmall to render the limbs more active, and to throw the weight of the muſcles nearer to the trunk. Muſcles have the following attachments: 1ſt. To bone, often penetrating the ſubſtance. 2dly, To periosteum. 3dly, To cartilage, as thoſe of the ribs. 4thly, To perichondrium, as thoſe of the external ear. 5thly, To ligaments. 6thly, To membranes, as thoſe of the eye. 7thly, To tendons, as the lumbricales. 8thly, To fleſh, as the tongue, uvula, &c. 9thly, To ſkin, as the muſcles of the face, &c.

Muſcles are divided into different kinds, as oblong, hollow, and mixed; the oblong are ſubdivided into different claſſes, rectilinear, having its fibres running in right lines. Half Penniform, its fibres running as the feathers of a quill on one ſide of the barrel. Complete Penniform; having its fibres diſpoſed as the feathers are on both ſides the barrel of a quill: and radiated; the direction of whoſe fibres is from a centre to a circumference. Hollow muſcles are thoſe ſurrounding cavities, having their fibres of different lengths, and in different directions, as the heart, inteſtines, &c. Mixed muſcles, ſuch as partly ſurround cavities, as thoſe of the abdomen. Every muſcle is divided into head, belly, and tail, ſo named from drawing a compariſon with the mouſe. Theſe muſcles, beſides tendons, have appendages, 1ſt, faſciæ, which are broad tendinous expanſions, or, aponeuroſes, to keep parts in their ſituation. 2dly, Thecæ, annular, or, tranſverſe ligaments, to keep tendons from ſtarting. 3dly, Trochleæ, to alter the direction of tendons. 4thly, Burſæ tendinibus ſubjectæ, or ſacculi mucoſi, where tendons or ligaments play over bones: they contain ſynovia, and prevent abraſion.

SECT. I.

ON THE MUSCLES OF THE ABDOMEN.

AFTER having removed the common integuments from the fore part of the abdomen, the muſcles of the belly appear: the anterior part of the parietes is covered by a broad thin tendinous expanſion, marked in different parts by lines, which are diſtinguiſhed by the following names: in the middle line of the body, extending from the xyphoid cartilage to the ſymphiſes pubis, is a white line, called linea alba, its breadth increaſes from the xyphoid cartilage to the umbilicus, then decreaſes to the pubes; on each ſide is a curved line, called linea ſemilunaris; between the cartilaginous margin of the cheſt on the fore part and the navel, are three or four tranſverſe lines, called lineæ tranſverſæ, the abdominal muſcles are five pairs in number, and ariſe in the following order:

NAME.	ORIGIN.	INSERTION.	USE.
OBLIQUUS DESCENDENS, *vel* **OBLIQUUS EXTERNUS**	By ſlips from the eight inferior ribs, about two inches from the cartilaginous margin of the cheſt; the four ſuperior making digitations with the *ſerratus major anticus*; the four inferior with the *latiſſimus dorſi*.	Inſerted into the whole length of the linea alba on the fore part, below fleſhy, to the outer labrum of the ſpine of the illium, as far as the anterior ſuperior ſpinous proceſs; from the ſuperior ſpinous proceſs to the os pubis, tendinous, which is continued into the faſcia of the thigh; this, called pouparts ligament, is perforated making the ring of the abdominal muſcle, for the paſſage of the ſpermatic cord in the male, and round ligaments in the female.	To compreſs the abdomen in expiration; aſſiſts in the expulſion of the urine, fæces, and fœtus; when both act, the body is bended forwards; when one acts unaſſiſted by other muſcles, the body is turned to a ſide.

NAME.	ORIGIN.	INSERTION.	USE.
Obliquus ascendens, *vel* obliquus internus.	Tendinous from the faſcia lumborum, from the middle part of the ſpine of the ilium, from the anterior part of the ilium and os pubis.	Is inſerted into the cartilaginous margin of the thorax, and into the whole length of the linea alba.	In its action ſimilar to the former; the fibres decuſſating, ſtrengthen the parietes
Transversalis abdominis.	By a broad thin tendon, from the tranſverſe proceſſes of the vertebræ lumborum, fleſhy from the inner margin of the ſpine of the ilium, from the internal part of the cartilaginous margin of the cheſt, making digitations with the diaphragm.	Is fixed by a broad tendon into the whole length of the linea alba; its tendon paſſes behind and before the rectus, & forms a ſheath.	Compreſſes the lateral parts of the abdomen in reſpiration.
Rectus abdominis.	By a thick ſhort tendon from the ſuperior anterior part of the os pubis, is divided into three or four diſtinct muſcles by the *lineæ tranſverſæ.*	Is inſerted into the cartilages of the 5th, 6th, and 7th ribs, near the ſternum.	It compreſſes the anterior part of the abdomen, bends the trunk, and raiſes the pelvis towards the trunk.
Pyramidalis.	Fleſhy from the anterior middle part of the os pubis.	Is inſerted into the linea alba, a little below the umbilicus	Compreſſes the bladder, & the lower part of the cavity of the abdomen.

SECT. II.

ON THE MALE ORGANS OF GENERATION.

THE Male organs are divided into the internal and external parts, all contained within the pelvis, internal; all without, external: in order to underſtand them, they muſt be traced in the courſe of the ſecretion of ſemen, &c. The teſticles, though lodged in the ſcrotum, receive their blood-veſſels from the aorta. The blood-veſſels going to the teſticles, called ſpermatic; each teſticle receives an artery, that ariſes from the fore part of the aorto, immediately below the emulgents. The veins accompany the arteries, that on the right ſide opening into the fore part of the cava inferior, near the emulgent vein; that on the left, opening into the emulgent vein on the ſame ſide. The nerves come from the par vagum and intercoſtal, and attend the arteries.

The Spermatic chord conſiſts of the following parts: the ſpermatic artery and vein, nerves, lymphatic veſſels, and the vas deferens, or excretory duct; theſe are united by reticular ſubſtance, and have a common covering, called tunica vaginalis communis: this is formed by an expanſion of the tendon of the external oblique, cremaſter muſcle, and the ligamentous remains of a proceſs of the peritonæum. Tunica vaginalis teſtis, inveſts the external part of the teſticle.

Tunica vaginalis propria teſtis, is a complete bag or reflected membrane, immediately inveſting the body of the teſtis; in it the water collected in the hydrycele is contained. The teſticle is divided into two parts; the larger anterior rounded part called body; on the back part, an oblong proceſs, called epididymis; theſe are covered with tunica albuginea. The outer part of the tunica albuginea, formed by the inner portion of the tunica vaginalis propria teſtis. The internal part of the teſticle conſiſts of a congeries of tubes, extremely convoluted; theſe are interſected by ſmall ligamentous chords, which paſs from one ſide of the tunica albuginea to the other.

The tubes of the teſticle unite at the upper part, and form the rete teſtis; the tubes uniting form about thirteen larger tubes, called vaſa afferentia; theſe run on, to form the upper part of the epididymis. The epididymis is one long convoluted tube, made by the union of the vaſa afferentia; this becoming larger at the extreme or lower part, makes the vas deferens, which being continued on, forms a part of the ſpermatic chord. The blood veſſels of the teſtes run convoluted, or in a ſerpentine direction; hence they have been called vaſa pyramidalia. The extreme branches of the ſpermatic veſſels ramify on the tubes of the teſtis, into which the ſemen is ſecreted.

The teſticles, in the early period of life, are ſituated behind the peritonæum, in the cavity of the abdomen, near the kidnies; they generally deſcend about the ſeventh month, but frequently later, and ſometimes not till the time of puberty; in ſome inſtances, they have remained in the cavity of the abdomen throughout life.

The teſticles deſcend in the following manner: from the lower part of each teſticle, going to be inſerted into the ſcrotum, is a ligamentous ſubſtance, called the gubernaculum; the teſticle, gradually deſcending, takes with it a proceſs of the peritonæum; in its paſſage through the ring of the external oblique, it receives a tendinous expanſion from that muſcle, which, with the cremaſter, forms the tunica vaginalis communis; immediatel after the deſcent of the teſticle, is a vaginal ſheath, leading from the cavity of the abdomen to the body of the teſtis; the gut protruding immediately after the deſcent of the teſtis, forms the hernia congenita, the teſtis and gut being in contact.

Shortly after the deſcent of the teſtis, the peritonæal proceſs, at its upper part, becomes obliterated; the lower part, remaining open, forms the tunica vaginalis, propria teſtis.

SECT. III.

SCROTIUM.

THE Scrotium is a purſe or bag formed for the reception of the teſtes; externally, is formed of common integuments; internally, of a bed of looſe reticular ſubſtance, in which the teſtes are lodged; it is divided into two ſides by a ſeptum; on the outer part, has a raphe. The dartos muſcle cannot be demonſtrated.

SECT. IV.

PENIS.

THE Penis conſiſts of three ſpungy bodies, viz. two corpora cavernoſa, and one corpus ſpongioſum urethræ. The two cavernoſe bodies are covered by a ſtrong inelaſtic ligamentous membrane, and are united to each other from the anterior part, two thirds of their whole length; at their poſterior part, they diverge, and form the cruræ penis; theſe are attached to the bones of the pubis; between the two corpora cavernoſa, is the pecten; their internal parts interſected by ſmall ligamentous fibres. The corpus ſpongioſum urethræ has the urethra paſſing through it, and begins from the membranous part of the urethra; at that part it is enlarged, forming the bulbous part of the urethra; is continued on the under part of the corpora cavernoſa, and at the end of theſe, is enlarged, covering their extremities, and forming, what has by ſome been called, the corpus quartum or glans penis; it has a more delicate ligamentous covering than the corpora cavernoſa. The corpora cavernoſa and corpus ſpongioſum are united by condenſe reticular ſubſtance; their internal texture are nearly the ſame; and theſe are covered by the common integuments, but have no fat. The arteriæ pudicæ enter the crurœ penis, and ſome branches paſs into the corpus ſpongioſum urethræ, and ramify to all parts; a ſmall part runs in dorſo penis, ſupplying the integuments with blood; this blood is returned by two veins; one lying in dorſo penis, in the ſpace between the two corpora cavernoſa, and returns the blood from the centre of the penis, which is carried to it for the purpoſe of erection; this is called vena magna ipſius penis; the other, ſuperficial, returns the blood from the integuments, and is called vena tegmentorum. The glans penis is covered by a folding of the ſkin, called præputium; this, at its lower part, is attached to the under ſide of the glans, takes the name of the frænum. The following muſcles, are ſituated about the penis and anus.

NAME.	ORIGIN.	INSERTION.	USE.
Erector penis *ſeu* iſchio-cavernoſus.	From the branch of the iſchium and pubis.	Into the crus penis by a broad tendon, ſpread over it as far as the ſymphyſis pubis.	Does not erect the penis, but gives to it greater turgeſcency in erection.
Accelerator urinæ *ſeu* ejaculator ſeminis.	From the internal part of the branch of the os pubis, and from the ligamentous part of the crus penis.	Meets with its fellow from the oppoſite ſide, and uniting with it in a common tendon, the two form a complete penniform muſcle, covering the whole bulb of the urethra.	Expels the laſt drops of the urine, and aſſiſts in the ejection of the ſemen.
Transversalis perinæi.	From the inſide of the tuberoſity of the iſchium.	Into the corpus ſpongioſum, near the bulb.	Dilates the bulb, for the reception of the ſemen.
Sphincter ani.	Surrounds the lower part of the gut, and is ſpread under the ſkin, about an inch from the verge of the anus.	Its fibres, being circular, terminate in each other.	Conſtricts the anus and prevents the involuntary diſcharge of the fæces.

NAME.	ORIGIN.	INSERTION.	USE.
Levator ani.	Ariſes from the internal part of the pelvis, a little below its bony brim.	Is a broad muſcle, and inſerted into the lower ſide of the rectum.	Prevents an inverſion of the rectum in the excluſion of the fæces.
Cremastor.	From the internal oblique, near the junction of the ilium and pubis over which it paſſes along with the ſpermatic cord.	Into the ſunica vaginalis teſtis.	To draw up the teſticle and compreſs it in coition.

SECT. V.

A SIDE VIEW OF THE CONTENTS OF THE PELVIS.

THE contents of the pelvis in the male, are the bladder on the anterior part; that ſide only, which is next to the cavity of the abdomen, covered by peritonæum; on the poſterior part, following the ſweep of the ſacrum, is the rectum; at the under part of the bladder, between it and the rectum, veſiculæ ſeminales; between theſe, ſurrounding the neck of the bladder, is the proſtrate gland; behind the peritonæum, are the ureters, bringing the urine from the kidneys to the bladder; and the vaſa deferentia, conveying the ſemen from the teſticles to the veſiculæ ſeminales.

SECT. VI.

VESICULÆ SEMINALES.

WHEN cut through tranſverſely, exhibit the appearance of cells; but when carefully unravelled, are found to conſiſt of one tortuous tube; the internal ſurface is villous and extremely vaſcular. The vas deferens enter the ring of the abdominal muſcle, and when in the cavity of the abdomen, ſeparates from the blood veſſels, and paſſing over the brim of the pelvis, gets to the under part of the bladder, and opens into the duct of the Veſiculæ Seminalis; Veſiculæ Seminales attached to the bladder by reticular ſubſtance.

SECT. VII.

BLADDER.

THE Bladder receives a partial covering from the peritonæum; has a coat conſiſting of muſcular fibres, called Detruſor urinæ; this coat may be divided into two layers, one external, conſiſting of fibres running from the neck towards the fundus of the bladder; and the other of circular fibres, inveſting it tranſverſely; the internal part is lined by a thin denſe membrane to prevent tranſudation; is vaſcular, but not villous, and this membrane has a mucus ſecreted on it. When the penis is cut through on the back part, and the urethra and bladder laid open, the following parts appear: the recipient orifices made by the openings of the urethers, and the expellent orifice; theſe form nearly an equilateral triangle. The neck of the bladder, in the human ſubject, is an imaginary line. From the expellent orifice of the bladder to the bulb of the urethra, is called membranous part of the urethra; the upper portion is inveſted by the proſtrate gland; on the back part is a ridge, called Caput Gallinaginis, in the middle of which, is a blind hole, called foramen cœcum; on each ſide of which are the openings of the ſeminal ducts, called oculi gallinaginis; the internal part of the bladder ſeems continued on, to form the internal membrane of the urethra. The whole length of the urethra is ſtudded with glands, that have long excretory ducts, called lacunæ; one of theſe ſituated about half an inch within the meatus urinarius, at the upper part of the paſſage, is large, and called lacuna magna. The mucus, for the lubrication of the urethra, is ſecreted by theſe glands.

SECT. VIII.

PROSTATE GLAND.

THE Proſtate Gland is of a triangular figure, nearly repreſenting the form of a heart, as painted on cards; it is extremely vaſcular; and ſecretes a brown fluid, that is poured into the upper part of the urethra, which mixes with the ſemen at the time of coition.

Explanation to the PLATE *on* THE MALE ORGANS OF GENERATION.

FIGURE I.

A poſterior View of the Male Organs.

A, The under ſurface of the bladder, or that ſide of it which comes in iumediate contact with the rectum; the letter A is placed on what is called the fundus of the bladder. B B, The two ureters. C C, Vas deferens. D D, Veſiculæ ſeminales. E, Proſtrate glands. F F, Cowper's glands. They are two ſmall glands, each of them nearly the ſize of the common pea, lately diſcovered by Dr. Cowper.

G G, Acceleratores muſcle; the bulb of the urethra underneath them is the cauſe of their ſhape in the print.

H, The urethra, or common paſſage for the urine and the ſemen.

I I, Muſculi erectores penis.

K K, The corpora cavernoſa penis.

L, Glans penis; juſt above the letter L was the inſertion of the frœnum, or bridle of the penis, but unavoidably was cut away with the ſkin that covered it.

FIGURE II.

An anterior View from the ſame Sabject, with the Bladder and Urinary Canal laid open.

A, The upper ſurface of the bladder, or that ſide of it which comes in contact with the ſmall inteſtines.

B, The internal coat of the bladder, or the inner ſurface where the urine is contained.

C, C, Two orifices of the ureters by which the urine comes from the kidney into the bladder.

D, D, The ureters. E, E, Vaſa deferentia.

F, F, Portions of the veſiculæ ſeminales ſeen.

G G, Proſtrate gland.

H, H, The two cut edges of the urethra.

I I, Roſtrum or caput gallinaginus.

K, K, Two orifices through which the ſemen paſſes at the time of the coctus, from the veſiculæ ſeminales; round theſe two orifices is a circle of excretory ducts, perceptible to the naked eye, which belong to a like number of glands, the whole of the urethra being filled with them, but not apparent enough to be repreſented iu the print.

L, L, L, Lacunæ of the urethra, or oblong holes leading to capillary blood veſſels.

M, Orifice of the urethra.

FIGURE III.

A View of the Proſtrate Gland, Veſiculæ Seminales, Bladder, and Rectum in Situ.

A, Oſſa pubis. B, Symphyſes pubes.

C, Ramus of the os iſchium.

D, D, The two cut edges of the urethra; it being divided to ſhew the paſſage of the ſeminal ducts into it.

E, Caput gallinaginus.

F, F, Occuli gallinaginus, or the two orifices of the veſiculæ ſeminales.

G, G, The proſtrate gland divided to ſhow the ducts of the veſiculæ ſeminales.

H, H, Veſiculæ ſeminales. I, I, Vaſa deferentia.

K, The ſame veſſel going round the poſterior ſurface of the bladder, and coming over the brim of the pelves to go down to the teſticle.

L, L, L, The bladder. M, M, The rectum.

FIGURE IV.

A View of the teſticle, with its coats; in this Preparation there is little or no diſſection, but as it is pulled out of the ſcrotum or purſe.

A, The ſpermatic chord.

B, Tunica vaginalis, the coat which covers this and the teſticle.

C, The cremaſter muſcle.

FIGURE V.

The Spermatic Chord injected, and the Coverings removed; we now diſcover in the Chord four Sets of Veſſels; viz. The Vas Deferens, the Arteries, the Veins and Abſorbents; alſo the Nerve; all of them going and coming from the Teſticle.

A A, The ſpermatic plexus. B, Vas deferens.

C, Epididymis. D, Convolutions of the epididymis.

E, The body of the teſticle, covered by the tunica albuginea, with a few of its blood veſſels indiſtinctly ſeen.

SECT. IX.

MUSCLES OF THE HEAD, FACE, &c.

NAME.	ORIGIN.	INSERTION.	USE.
Corrugator superciliі.	From the lower middle part of the os frontis, from the oſſa naſi, and naſal proceſs of the maxillary bone.	Paſſing obliquely upwards, and outwards is inſerted into the ſkin of the forehead, above the eyebrow.	Brings the ſkin of the forehead towards the noſe, as in frowning.

MUSEUM

NAME.	ORIGIN.	INSERTION.	USE.
OCCIPITO FRONTALIS.	The frontal portion from the inferior part of the os frontis and ſuperior orbiter proceſs; the occipital portion from the tranſverſe occipital ridge.	Each portion forming a broad thin tendon, unite at the upper part of the head, this tendon joining with its fellow below on the oppoſite ſide, forms a tendinous expanſion, covering the upper part of the ſcull.	Corrugates the ſkin of the ſcalp and forehead.
APERIENS PALPEBRAM	The lower part of the orbit, near the foramen opticum.	The cartilage of the upper eye-lid.	Raiſes the upper eye-lid, and opens the eye.
ORBICULARIS PALPEBRARUM, *ſive Sphincter Oculi*	By a ſmall round tendon from the internal part of the os naſi, and naſal proceſs of the maxillary bone.	Spread out under the ſkin of the eye-lids, covering the upper part of the cheek.	By raiſing the lower eye-lid, and depreſſing the upper one, cloſes the eye.
RINÆUS *Naſalis ſeu Rectus Naſi.*	The upper part of the os naſi, and naſal proceſs of the maxillary bone.	The cartilaginous part of the noſe.	By drawing the ala naſi outwards, dilates the noſe.
ZYGOMATICUS, *ſive Diſtortor Anguli Oris.*	The Zygoma.	The angle of the lips.	Raiſes the angle of the mouth.
ELEVATOR LABIORUM COMMUNIS.	The outer part of the maxilla ſuperior	The angle of the mouth.	Raiſes the lip.
ELEVATOR LABII SUPERIORIS PROPRIUS ALÆQUE NASI.	Is a broad muſcle, ariſing from that part of the maxilla ſuperior, below the orbit.	The upper lip and ala naſi.	Raiſes the lip.
ORBICULARISORIS, *vel Sphincter Labiorum.*	The fibres of this muſcle are orbicular and ſpread out under the ſkin of the lips.	The ſkin of the lips.	By contracting the ſkin of the lips, cloſes the mouth.
DEPRESSOR LABIORUM COMMUNIS, *ſive Triangularis.*	The fore part of the baſis of the lower jaw.	The ſide and angle of the lips.	Depreſſes the angle of the mouth.
DEPRESSOR LABII INFERIORIS PROPRIUS.	The fore part of the baſis of the lower jaw.	The middle part of the lower lip.	Depreſſes the under lip.
DEPRESSOR LABII SUPERIORIS PROPRIUS.	The alveolar proceſſes on the fore part of the maxilla ſuperior.	The ſuperior part of the upper lip.	Depreſſes the upper lip.
ELEVATOR LABII INFERIORIS PROPRIUS.	The alveolar proceſſes on the fore part of the lower jaw.	Into the lower lip & ſkin of the chin.	Raiſes the lower lip and chin.
BUCCINATOR.	The alveolar proceſſes of both jaws.	The angle of the lips.	Contracts the cavity of the mouth, counteracts the tongue, and applies the food to the circle of the teeth in maſtication
QUADRATUS GENÆ, *vel* LATISSIMUS COLLI.	The ſkin of the breaſt and ſhoulder.	Is ſpread out under the ſkin of the neck, and inſerted into the baſis of the lower jaw, ſkin of the cheek and angle of the lips.	Depreſſes the lower jaw and lips.
ANTERIOR AURIS.	The os malæ and maxilla ſuperior.	On the anterior cartilaginous part of the meatus auditorius.	Dilates the meatus auditorius.
ELEVATOR AURIS.	The faſcia of the temporal muſcle.	The cartilage of the ear.	Raiſes the auricula.
RETRACTOR AURIS.	The tranſverſe proceſs of the occipital ridge, and faſcia of the occipito frontalis.	The poſterior part of the concha.	Dilates the meatus auditorius.
DIAPHRAGINA.	Has by ſome been conſidered as conſiſting of two muſcles; on the anterior part, its fibres are radiated; on the back part, rectilinear; the anterior part ariſes about an inch within the cartilaginous margin of the thorax, making digitations with the tranſverſalis abdominis; the poſterior part, called crura of the diaphragm, ariſes from the anterior and lateral parts of the bodies of the three or four ſuperior vertebræ lumborum, and from the fore part of the body of the laſt vertebra dorſi; between the crura, the œſophagus paſſes into the cavity of the abdomen.	The tendinous fibres of all parts of the muſcle unite in the middle, and form the centrum tendinoſum. This tendon is perforated to admit the cava inferior to pour its contents into the heart; it alſo admits of the aorta, thoracic duct, and œſophagus, to paſs from the cheſt into the abdomen.	Is concave towards the cavity of the abdomen; convex towards the cavity of the cheſt: in its action endeavours to reduce itſelf into a ſtraight line; enlarges the cavity of the cheſt, in inſpiration, and counteracts the abdominal muſcles.

SECT. X.

OS HYOIDES AND CARTILAGES OF THE LARYNX.

THE Os Hyoides, in its form, repreſents the *v* conſonant; its anterior part or baſis is broad, printed by the attachment of muſcles; on its inner part it is hollowed, having a ligament inſerted into it, by which it is attached to the fore-part of the thyroid cartilage; its lateral parts called horns; between the baſis and horns of this bone is a little proceſs, called the graniform appendage, is attached to it by a ligament. The horns of the os hyoides are connected to the ſuperior proceſſes of the thyroid cartilage by ligaments; in the middle of each ligament is a graniform cartilage. All parts of this bone ſtrongly printed by the attachment of muſcles.

The Thyroid Cartilage forms the anterior part of the larynx, or that part of the throat called pomum adami, which is hollowed on the outſide; at the ſuperior poſterior part, there is a pair of proceſſes, by which it is connected with os hyoides; at the inferior, a pair of proceſſes, by which it is articulated to the cricoid cartilage; at the ſuperior poſterior part, it is articulated with the aretenoid cartilages; and on its fore part, is printed by muſcles.

Cricoid Cartilage is broad at the back part, narrow before like a ring; is articulated with the lower part of the thyroid cartilage, making the inferior part of the larynx; the ſuperior parts of the larynx are formed by a pair of cartilages, called aretenoid; each aretenoid cartilage is triangular; the baſis articulated to the ſuperior poſterior part of the cricoid; their apices approach each other, and form the aperture of the glottis: to theſe cartilages, the ſacculi laryngis are attached.

SECT. XI.

MUSCLES OF THE NECK, TONGUE, &c.

NAME.	ORIGIN.	INSERTION.	USE.
MASSITER.	By three heads; the firſt from the maxillary bone, near its junction with the os malæ; the ſecond from the zygomatic proceſs of the os malæ and os temporis; the third from the internal part of the zygoma.	The external part of the proceſs of the lower jaw, from the angle, extending almoſt as far forwards as the middle part of it.	Raiſes the jaw, and carries it backwards in the act of maſtication.

NAME.	ORIGIN.	INSERTION.	USE.
TEMPORALIS *ſive Crotaphitei.*	From the whole temporal foſſa, is covered by a ſtrong tendinous expanſion which gives origin to ſome of the fibres.	The coronoid proceſs of the lower jaw.	Raiſes the jaw.
PTERIGOIDEUS INTERNUS, *ſeu maſſiter internus.*	Ala pterigoidea interna, and foſſa pterigoidea.	The internal part of the proceſs of the lower jaw, oppoſite to the maſſiter.	Aſſiſts the two former muſcles in raiſing the lower jaw.
PTERIGOIDEUS EXTERNUS.	The ala externa pterigoidea, and from the adjacent parts.	The condyloid proceſs of the lower jaw.	Moves the jaw laterally.
DIGASTRICUS, *ſeu biventer.*	Has two fleſhy bellies and one middle tendon; the poſterior part ariſes from a cavity on the inner ſide of the maſtoid proceſs; forms a round tendon which paſſes through the tendon of the ſtilohyoideus, is tied by a ligament to the lateral part of the baſis of the os hyoides.	The anterior belly is inſerted into a tubercle, on the inſide of the baſis of the lower jaw, near the ſymphyſis.	Depreſſes the lower jaw.
MASTOIDÆUS, *ſeu ſterno elido maſtoidæus.*	By a ſtrong, round tendon from the anterior ſuperior part of the firſt bone of the ſternum, and by a broad, thin tendon from the ſuperior ſternal extremity of the clavicle.	The inferior external part of the maſtoid proceſs; and by broad thin tendon into the anterior part of the tranſverſe occipital ridge.	Moves the face to the oppoſite ſide; when the two act, the head is bended forwards.
STERNO-HYOIDÆUS.	The inner part of the firſt bone of the ſternum, and from the cartilage of the firſt rib.	The fore part of the baſis of the os hyoides.	Draws the os hyoides downwards.
MYLO-HYOIDÆUS.	Fleſhy from all the internal edges of the alveolar proceſſes of one half of the lower jaw.	The inferior margin of the os hyoides.	Draws the os hyoides upwards, forwards and laterally, according to the action of the different parts of the muſcle.
GENIO-HYOIDÆUS.	From a tubercle on the inſide of the lower jaw, near the ſymphiſis.	The whole length of the os hyoides.	Raiſes the bone and brings it forwards.
STILO-HYOIDÆUS.	By a round tendon from the middle part of the ſtiliform proceſs.	The baſis of the os hyoides, near its horn.	If one muſcle acts it is moved to a ſide; if both act it is raiſed and carried backward.
STILO-CHONDRO-HYOLDAEUS, *ſeu ſtilo-hyoidæus alter.*	The lower part of the ſtili-form proceſs.	The graniform appendage of the os hyoides.	In its action aſſiſts the preceding muſcle.
CORACOHYOIDÆUS.	The ſuperior coſta ſcapulæ, and from the ligament that forms the lunated cavity into a hole, paſſing obliquely up the neck; has a middle tendon where it is preſſed upon by the ſterno maſtoidæus.	By a broad thin tendon, into the fore part of the baſis of the os hyoides.	Draws the os hyoides obliquely downwards and backwards.

NAME.	ORIGIN.	INSERTION.	USE.
GENIO-GLOSSUS.	From a tuberoſity, on the internal middle part of the lower jaw, the fibres radiate from its origin.	Into the tongue, its whole length.	Being a radiated muſcle, different portions acting will produce different effects.
HYO-GLOSSUS.	The horn, and one half the baſis of the os hyoides.	Laterally into the baſis of the tongue.	When one acts, the tongue is carried obliquely to a ſide, when both, downwards and backwards.
STILO-GLOSSUS.	The ſtili-form proceſs.	The middle and poſterior part of the ſide of the tongue.	Raiſes the tongue & carries it to one ſide.
LINGULALIS	Conſiſts of fibres running from the apex to the baſis of the tongue.		Shortens the tongue.
STERNOTHYREOIDÆUS.	The internal part of the firſt bone of the ſternum.	An oblique ridge, on the ſide of the thyreoid cartilage.	Depreſſes the larynx.
HYO-THYREOIDÆUS.	The anterior part of the baſis of the os hyoides.	The oblique ridge, on the ſide of the thyreoid cartilage.	Raiſes the larynx.
CRICO-THYREOIDÆUS.	The anterior part of the cricoid cartilage.	The inferior lateral part of the thyreoid cartilage.	By moving the thyreoid cartilage to a ſide, enlarges the cavity of the larynx.
ARYTÆNOIDEUS MAJOR	Fleſhy from the baſis of the arytænoid cartilage on the one ſide.	The whole length of the arytænoid cartilage on the oppoſite ſide.	Brings the arytænoid cartilages to each other, and contracts the aperture of the glottis.
ARYTÆNOIDEUS MINOR, *ſeu aryto-aritenoideus.*	A ſmall muſcle ariſing from the lateral part of the baſis of the arytænoid cartilage on the one ſide	Paſſing tranſverſely to the oppoſite cartilage is inſerted into it.	Aſſiſts the former muſcle in its action.
CRICO-ARYTENOIDEUS POSTICUS.	The poſterior part of the cricoid cartilage.	The baſis of the arytænoid.	Opens the glottis.
CRICO-ARYTENOIDEUS LATERALIS.	The lateral part of the cricoid cartilage.	The outward ſide of the arytænoid.	Opens the glottis.
THYREO-ARYTÆNOIDÆUS.	The whole length of the internal concave part of the thyreoid cartilage.	The internal part of the baſis of the arytænoid.	Aſſiſts in contracting the aperture of the glottis.
CEPHALO-PHARYNGEUS.	The cuneiform proceſs of the os occipitis.	This and the ten following muſcles form the pharynx.	
Chondro-pharyngæus.	The graniform appendage of the os hyoides.		
Crico-pharyngæus.	From the cricoid cartilage.		
Gloſſo-pharyngæus.	The baſis of the tongue.		
Hyo-pharyngæus.	The horn of the os hyoides.		
Pterigo-pharyngæus.	The pterigoid proceſs of the ſphænoidal bone.		

ANATOMY.

NAME.	ORIGIN.	INSERTION.	USE.
SALPINGO-PHARYNGEUS.	The extreme part of the euſtachian tube.	All theſe muſcles, from their various origins, meet their fellows, from the oppoſite ſide, and unite in a middle tendon; together they form a muſcular bag, to which the food after maſtication is tranſmitted, and, by their action is thence propelled into the œſophagus.	
Syndeſmo pharyngæus.			
Stilo-pharyngæus.	The root of the ſtili-form proceſs.		
Thyreo-pharyngæus.	The lateral part of of the thyreoid cartilage.		
GLOSSO STAPHILINUS.	The lateral part of the tongue.	Near the middle of the uvula.	When one acts the uvula is moved to a ſide, when both act, is depreſſed.
PALATO STAPHILINUS.	The ſuture of the os palati.	The ſide of the palati.	Moves the palate forwards & downwards.
SALPINGO STAPHILINUS, *ſeu Pteri Staphilinus.*	The anterior part of the euſtachian tube.	The baſis of the uvula.	Moves the uvula upwards and backwards.
THYREO STAPHILINUS.	The ſuperior part of the thyroid cartilage.	The uvula.	Shuts up the paſſage between the noſe and mouth in deglutition.
PECTORALIS MAJOR.	One half of the anterior part of the clavicle; from the lateral part of the ſternum; from the cartilages of the fifth and ſixth ribs.	The outer ridge of the canal, into which the tendon of the long head of the biceps flexor is lodged	Brings the arm inwards, and depreſſes it, when raiſed.
PECTORALIS MINOR, *ſeu Serratus Minor Anticus.*	The third, fourth, and fifth ribs.	By a ſhort round tendon into the coracoid proceſs of the ſcapula.	Aſſiſts the former in depreſſing the arm, & brings the ſcapula forwards.
Subclavius.	Tendinous from the under part of the ſcapular extremity of the firſt rib, and paſſing obliquely between the clavicle and firſt rib.	The ſuperior part of the firſt rib, near the ligament by which it is tied to the clavicle.	Depreſſes the ſcapular extremity of the clavicle.
Intercoſtales Externi.	The inferior margin of each rib, and running obliquely forwards.	Into the ſuperior margin of the rib below.	Raiſe the ribs & enlarge the cavity of the cheſt.
Triangularis Sterni.	The internal part of the xiphoid cartilage, from the lateral inferior parts of the ſternum.	Running obliquely upwards and outwards, is inſerted into the cartilages of the third, fourth, and fifth ribs.	By depreſſing the ribs, contracts the cavity of the cheſt.
Intercoſtales Interni.	Like the former, and paſſing obliquely, decuſſate the external.	The upper margin of each rib,	Raiſe the ribs.
Depreſſores Coſtarum Proprii. Ten pairs in number.	The internal part of the rib, near its articulation with the tranſverſe proceſs of the vertebræ,	Paſſing obliquely upwards & forwards are inſerted into the inferior margin of the rib above.	Depreſs the ribs & contract the cavity of the cheſt.
Trapezius vel Cucularius.	By a ſhort tendon from the middle part of the tranſverſe occipital ridge; from the ligamentum colli; from the ſpinous proceſs of the laſt vertebra colli; from the ſpinous proceſſes of the ten ſuperior vertebræ dorſi.	The fibres, from the ſuperior part, paſſing obliquely round the back part of the ſhoulder, are inſerted into the upper portion of the extremity of the clavicle and into the proceſſus acromion; all the middle and lower part, into the whole length of the ſpine of the ſcapula.	The fibres of this muſcle running into different directions, different parts acting independent of the whole, will produce different effects; the middle portion moves the ſcapula backwards; the upper portion raiſes it obliquely; the inferior portion depreſſes, and carries it backwards.
Latiſſimus Dorſi.	By a broad thin tendon from the poſterior part of the ilium; from the ſpinous proceſſes of the os ſacrum; from all thoſe of the vertebræ lumborum, and from the ſpinous proceſſes of the ſeven or eight inferior vertebræ dorſi, below the rhomboides.	A ſmall ſlip is inſerted into the inferior angle of the ſcapula; the remaining part paſſing on, forms the outer fold of the axilla, and is inſerted into the outer part of the biceps muſcle, is lodged oppoſite to the inſertion of the pectoralis major.	Depreſſes the arm, and carries it backwards.
Elevator Scapulæ, ſeu Muſculus Patientiæ	By ſlips, from the tranſverſe proceſſes of the four ſuperior vertebræ colli.	The ſlips uniting, form one muſcle, which is inſerted into the ſuperior angle of the ſcapula.	Raiſes the ſcapula, and depreſſes the arm when raiſed.
Rhomboides Minor.	From a part of the ligamentum colli, and the ſpine of the vertebra colli.	That part of the baſis of the ſcapula, which is above the ſpine.	Carries the ſuperior angle of the ſcapula upwards and backwards.
Rhomboides Major.	The ſpinous proceſſes of the four or five ſuperior vertebræ dorſi.	All that part of the baſis of the ſcapula below the ſpine.	Carries the ſcapula obliquely upwards and backwards.
Serratus Minor Anticus.	By ſlips from the eight ſuperior ribs.	The whole length of the baſis of the ſcapula on its inner ſide.	Rotates the ſcapula on its axis in the motion of the arm, and in ſtrong efforts, raiſes the ribs.
Serratus Superior Poſticus.	By a broad thin tendon, from the lower part of the ligamentum colli; from the ſpinous proceſs of the laſt vertebra of the neck; from the ſpines of the three ſuperior vertebræ of the back.	The ſecond, third, and fourth ribs by diſtinct ſlips.	By raiſing the ribs, enlarges the cavity of the cheſt.
Serratus Inferior Poſticus.	By a broad thin tendon, from the ſpinous proceſſes of the two inferior vertebræ dorſi, and of the two ſuperior vertebræ lumborum	The inferior margin of the three or four laſt ribs, paſſing obliquely upwards.	Depreſſes the ribs in the expiration.
Splenius.	By ſeveral long ſmall tendons, from the ſpines of the four ſuperior vertebræ dorſi; from that of the ſeventh vertebra of the neck, and from the whole ligamentum colli. This ligament principally formed by the union of the tendons of the two ſplenii, extending from the ſpinous proceſs of the ſecond vertebra colli to that of the laſt.	The tranſverſe proceſſes of the firſt and ſecond vertebræ colli; into the maſteoid proceſs, and a part of the occipital ridge.	When one muſcle acts, it counteracts the maſtoideus: when the two act, the head is carried backwards.

NAME.	ORIGIN.	INSERTION.	USE.
Complexus.	By tendons, from the tranſverſe proceſſes of the ſix or ſeven ſuperior vertebræ dorſi, and from the tranſverſe proceſſes of the ſix inferior vertebræ colli.	The under part of the os occipitis.	When one acts, the head is carried to a ſide; when both act, the head, if bended, is raiſed, and carried backward.
Trachælo-maſtoidæus, ſeu par tertium Fallopii	By ſlips from the tranſverſe proceſſes of the two ſuperior vertebræ dorſi, from thoſe of the three or four inferior vertebræ colli.	Paſſing up the neck under the ſpleneus, is inſerted by a thin tendon into the middle poſterior part of the maſtoid proceſs.	Aſſiſts the complexus.
Rectus major poſticus.	From one point of the ſpinous proceſs of the ſecond vertebræ colli.	Paſſing obliquely upwards and outwards, is inſerted into the os occipitis, behind the complexus.	Raiſes the head, and bends it a little backwards.
Rectus minor poſticus.	A ſmall tubercle on the back part of the atlas.	The os occipitis behind the foramen magnum occipitale.	Aſſiſts in raiſing the head.
Obiquus inferior.	The tranſverſe proceſs of the atlas.	The os occipitis, near the back part of the maſtoid proceſs.	Moves the head a little obliquely.
Obliquus inferior.	The ſpine of the dentata.	The tranſverſe proceſs of the atlas.	Rotates the head.
Rectus internus major.	The fore part of the tranſverſe proceſſes of the 3d, 4th, 5th, and 6th vertebræ colli.	The cuneiform proceſs of the os occipitis.	Bends the head forwards
Rectus internus minor.	The fore part of the body of the atlas.	The fore part of the foramen magnum.	Aſſiſts the former muſcle
Rectus lateralis	The tranſverſe proceſs of the atlas.	Near the maſtoid proceſs, into the os occipitis.	Bends the head a little to a ſide.
Muſculus Caput concutiens.	The oblique proceſſes of the ſecond and third vertebræ colli.	The root of the tranſverſe proceſs of the atlas.	Bends the head a little to a ſide.
Scalenus, divided into 4 muſcles.	Firſt, ariſes from the tranſverſe proceſſes of the fourth, fifth, and ſixth vertebræ colli.	The firſt rib, near its cartilage.	Theſe four parts of the ſcalenus, by raiſing the ribs, enlarge the cavity of the cheſt.
	The ſecond, ariſes by diſtinct tendons, from the tranſverſe proceſſes of the 2d, 3d, 4th, 5th, and 6th vertebræ of the colli.	The ſuperior middle part of the firſt rib.	
	The third, ariſes from the tranſverſe proceſſes of the fifth and 6th vertebræ of the neck.	The upper part of the ſecond rib.	
	The fourth, ariſes from the tranſverſe proceſſes of the two laſt vertebræ colli.	The poſterior part of each rib, near the tubercle.	
Longus colli.	The bodies of the four, or five ſuperior vertebræ dorſi.	The ſides of the bodies of the four inferior vertebræ colli.	Bends the ſpine.
Sacro Lumbalis.	In common with longiſſimus dorſi.	By ſlips into each rib, near its angle.	Depreſſes the ribs, and raiſes the trunk.
Acceſſorius ad ſacro lumbalem.	By ſlips from the eight or nine ſuperior ribs.	Fleſhy into the rib immediately below, lying within the attachments of the ſacro-lumbalis.	Aſſiſts the former muſcle in depreſſing the ribs.

NAME.	ORIGIN.	INSERTION.	USE.
Cervicalis deſcendens.	The tranſverſe proceſſes of the 3d, 4th, 5th, and 6th vertebræ colli.	The 3d, 4th, 5th, 6th, and 7th ribs, between the ſlips of the ſacro-lumbalis and longiſſimus dorſi.	Raiſes the ribs in inſpiration.
Levatores coſtarum proprii.	The tranſverſe proceſſes of the vertebræ dorſi, and running obliquely forwards and downwards.	Into the upper edge of each rib, except the firſt.	Raiſe the ribs, and enlarge the cavity of the cheſt in inſpiration.
Longiſſimus dorſi.	The faſcia lumborum, from the ſpinous proceſſes of the ſacrum, from the poſterior part of the ſpine of the ilium; from the ſpinous and tranſverſe proceſſes of the vertebræ lumborum, and at its origin, is blended with the ſacro-lumbalis.	Has a double inſertion by ſlips, into each rib, one ſlip being attached near the tubercle of the rib, the other midway between the angle and tubercle.	Depreſſes the ribs and raiſes the ſpine.
Semi-ſpinnlis.	The tranſverſe proceſſes of the ſix inferior vertebræ dorſi.	The ſpines of the ſix ſuperior vertebræ dorſi, and into that of the laſt vertebra colli.	Extends the ſpine.
Spinalis colli.	The tranſverſe proceſſes of the five ſuperior vertebræ dorſi.	Paſſing obliquely under the complexus, is inſerted into the ſpines of the 2d, 3d, 4th, and 5th vertebræ colli.	Extends the ſpine and raiſes the head
Tranſverſalis colli.	The oblique proceſſes of the four inferior vertebræ colli.	The roots of the the ſpines of the ſuperior vertebræ colli	Raiſes the head, and moves it obliquely backward.
Inter-ſpinales colli.	The points of the ſpinous proceſſes on their lower part.	The ſpinous proceſſes immediately beneath them.	Extend the ſpine.
Inter-tranſverſales colli.	The lower part of the tranſverſe proceſs of the vertebra above.	The upper part of the tranſverſe proceſs of the vertebra below.	Bend the neck laterally.
Inter-vertebrales.	The fore part of the body of the vertebra abcve.	Paſſing obliquely are inſerted into the ſide of the body of the vertebra below.	Bend the neck a little to a ſide
Tranſverſales dorſi interiores.	The tranſverſe proceſſes of all the vertebræ.	By a diſtinct ſlip, into the ſpinous proceſs of each vertebra.	Bend the ſpine laterally, and raiſe it.
Spinules lumborum.	Is blended with the ſacro-lumbalis, and longiſſimus dorſi.	The ſpinous proceſſes of all the vertebræ lumborum	By raiſing the lumbar vertebræ, extend the ſpine.
Tranſverſalis lumborum.	The oblique proceſſes of all the vertebræ lumborum.	The ſpines of all the lumbar vertebræ.	Aſſiſts the former.
Inter-tranſverſalis lumborum.	Are placed between all the tranſverſe proceſſes.		Bend the ſpine laterally.
Quadratus lumborum.	The inner labrum of the poſterior part of the ſpine of the ilium.	The tranſverſe proceſſes of the vertebræ lumborum, and into the laſt rib.	When one acts the ſpine is bended to a ſide; when both act, the body is bended forwards.

NAME.	ORIGIN.	INSERTION.	USE.
Pſoas parvus.	Fleſhy from the ſide of the ſuperior lumbar vertebra.	By a long tendon, into the brim of the pelvis.	Bends the ſpine on the pelvis, or raiſes the pelvis towards the ſpine.
Pſoas magnus.	The ſide of the body of the laſt dorſal vertebra, from the bodies and tranſverſe proceſſes, of all thoſe of the loins.	Paſſing over the brim of the pelvis, joins the tendon of the iliacus internus, and is inſerted into the little trochanter.	Bends the thigh, and carries it forward in progreſſion.
Iliacus internus.	All the internal ſurface of that part of the os-ilium, which is above the brim of the pelvis.	Paſſing over the brim of the pelvis, its tendon joins with that of the former muſcle, both having one common inſertion.	Aſſiſts the former.
Pectinalis.	The ſuperior, and interior part of the os-pubis.	The femur, a little below the little trochanter.	Bends the thigh forwards, and raiſes it.
Glutæus maximus.	The ſuperior part of the os coccygis, from all the ſpinous proceſſes of the ſacrum, from all the outer part of that bone below the ſpine of the ilium, from the ſacro-ſciatic ligaments, from the poſterior ſuperior part of the ſpine of the ilium, and from the faſcia, which covers the glutæus medius.	From theſe attachments it paſſes down to be inſerted by a large broad tendon, into the femur, a little below the great trochanter.	Extends the thigh, and carries it backwards.
Glutæus medius.	All the outer ſurface of the ilium, before that ſpace covered by the glutæus maximus.	By a broad tendon, the whole length of the great trochanter	Aſſiſts the former.
Glutæus Minimus.	The inferior, poſterior part, of the os ilium.	The great trochanter.	Aſſiſts the two former in extending the thigh.
Pyriformis, ſeu Iliacus Externus.	The inferior part of the os ſacrum, and from the os ilium near the ſciatic notch.	The cavity, at the root of the great trochanter.	Raiſes the thigh, and turns the toes outwards, by rotating the femur.
Germini.	The ſuperior ariſes from the ſpine of the iſchium; the inferior, from the inſide of the tuberoſity of the ſame bone.	Surrounding the tendon of the marſupialis, are inſerted into the cavity at the root of the great trochanter.	By rotating the thigh bone, turn the toes outwards.
Marſupialis, vel Obturator Internus.	The ligament which covers the obturator hole, and from the edges of the bone.	The cavity, at the root of the great trochanter.	Rotates the thigh bone obliquely outwards.
Quadratus Femoris.	The exterior ſide of the tuberoſity of the iſchium.	Paſſing tranſverſely, is inſerted into a ſpace between the two trochanters.	Carries the thigh backwards, and is a rotator.
Triceps; a title given to the four following muſcles: *Adductor Femoris longus.*	By a ſtrong tendon, from the ſuperior anterior part of the os pubis.	The linea aſpera, near the middle of the thigh bone.	

NAME.	ORIGIN.	INSERTION.	USE.
Adductor Femoris Congus.	By a broad tendon, from the os pubis, immediately under the gracilis.	That part of the linea aſpera, from the little trochanter to the inſertion of the former muſcle.	
Adductor Femoris brevis.	The exterior margin of the os pubis and iſchium, a little below the former.	Near the tendon of the gluteus maximus.	Theſe four muſcles, in their action, produce ſimilar effects.
Adductor Femoris magnus.	The tuberoſity of the iſchium, and from its inner ſide.	By a long round tendon, into the whole length of the linea aſpera.	In progreſſion they bend the thigh bone, and draw it inwards.
Obturator Externus.	The outer edge of the obturator hole, and from the ligament which covers it.	By a ſtrong tendon, into the cavity, at the root of the great trochanter.	Rotates the thigh bone, and turns the foot outwards.
Coccygæus.	The ſpine of the iſchium, and from a part of the ſacro ſciatic ligament.	The whole length of the os coccygis.	Raiſes the os coccygis.
Muſculus Membranoſus.	The anterior, ſuperior ſpinous proceſs of the ilium, is blended with the tendinous expanſion of the glutæus medius.	Forms the faſcia of the thigh, and is inſerted into the upper extremities of the tibia and fibula.	Extends the tibia, and rotates the foot a little outwards.
Sartorius.	The anterior ſuperior ſpine of the ilium.	Paſſing obliquely round the fore part of the thigh, is inſerted into the inner ſide of the head of the tibia.	Bends the leg.
Rectus Cruris.	The anterior ſuperior ſpine of the ilium.	The baſis of the patella.	Extends the leg.
Vaſtus Externus.	All the outer part of the femur, from the great trochanter to its lower extremity.	The baſis of the patella.	Extends the leg.
Vaſtus Internus.	The inſide of the femur, from the little trochanter to the inner condyle.	The upper part of the patella.	Extends the leg.
Cruræus.	The fore part of the thigh bone, joins the tendon of the three former muſcles, and	The baſis of the patella.	Extends the leg.
Gracilis.	By a broad thin tendon, from the os pubis, near the ſynphiſis.	The inner ſide of the tibia, near its head.	Bends the leg.
Seminervoſus, ſive Semitendinoſus.	The tuberoſity of the iſchium.	The inner poſterior ſpine of the tibia, about an inch below the inſertion of the ligament of the patella.	Bends the leg.
Semimembranoſus.	The tuberoſity of the iſchium.	The poſterior ſide of the tibia, near its head.	Bends the leg.
Biceps.	By two heads, the longer, originating from the tuberoſity of the iſchim, deſcends and joins with the ſhorter head, which ariſes from the linea aſpera	The outer part of the head of the fibula:	Bends the leg.

NAME.	ORIGIN.	INSERTION.	USE.
Gaſtrocnæmius.	By two heads; one from each condyle of the femur.	Below the joint, theſe unite in one common tendon; inſerted into the os calcis.	Extends the foot.
Solæus.	The poſterior parts of the tibia and fibula; joins with the tendon of the gaſtrocnæmius.	This and the former muſcle have one common tendon, called tendo achillis.	Aſſiſts the former muſcle in extending the foot.
Plantaris, vel Extenſor Tarſi Minor.	The outer condyle of the femur, and capſular ligament of the joint of the knee.	Its tendon paſſes obliquely between the tendons of the two former muſcles, and is inſerted into the os calcis.	Raiſes the foot and draws down the capſular ligament of the knee.
Tibialis Anticus.	The outer ſide of the tibia, near its upper part: ſome of its fibres originate from the faſcia of the leg.	Paſſing under the annular ligament, is inſerted into the os cuneiforme internum.	Bends the foot.
Tibialis Poſticu.	The poſterior ſuperior part of the tibia, from the fibula and interoſſeus ligament.	Its tendon, paſſing under the malleolus internus, is inſertedinto the upper and inner part of the os naviculare.	Extends the foot.
PERONÆUS LONGUS, *ſeu Peronæus Primus, ſeu Poſticus.*	The upper extremity of the fibula.	Its tendon, playing over the os cuboides, is inſerted into the os cuneiforme internum, and firſt bone of the great toe.	Moves the foot outwards, and bends it.
PERONÆUS SECUNDUS, *vel Anticus.*	The anterior middle part of the fibula.	Into the metatarſal bone ſuſtaining the little toe.	Bends the foot.
PERONÆUS TERTIUS, *ſeu Nonus Veſalii.*	The inferior anterior part of the fibula.	The metatarſal bone ſuſtaining the little toe.	Bends the foot.
Extenſor Digitorum Communis Longus.	The upper and outer ſide of the head of the tibia, and from the inner part of the fibula.	Its tendon, paſſing under the annular ligament, divides into four tendons, which go to be inſerted into the baſes of the ſecond bones of the leſſer toes.	Extends the toes.
Extenſor Digitorum Communis Brevis.	The upper part of the os calcis and cuboid bone, is divided into four tendons.	Theſe, joining the tendons of the former muſcle, have a common inſertion.	Aſſiſts the former.
FLEXOR DIGITORUM COMMUNIS LONGUS, *vel perforans, vel flexor profundus.*	The poſterior ſuperior part of the tibia: its tendon, paſſing under the malleolus internus, gets into the calcaneum.	Divides into four tendons, which are inſerted into the laſt bones of the leſſer toes.	Bends the toes.
PERFORATUS, *vel* FLEXOR-SUBLIMIS, *vel flexor digitorumcommunis brevis.*	The inferior part of the os calcis and faſcia of the foot.	Divides into four tendons, which are inſerted into the baſes of the ſecond bones of the leſſer toes.	Bends the toes.
MASSA CARNEA, *vel muſculus acceſſorius.*	The calcaneum and faſcia of the foot.	The tendon of the flexor longus.	Bends the leſſer toes.
Lumbricales.	The tendons of the flexor longus.	By a broad tendon, into the firſt bone of each of the leſſer toes. toes.	Bend the firſt joints of the toes.
Interoſſei.	The ſpace between the metatarſal bones.	The firſt bones of the leſſer toes.	Bend the firſt joints of the toes.
Adductor minimi digiti.	The bones of the tarſus, and from the metatarſal bone of the ſecond toe.	The ſide of the firſt bone of the little toe.	Draws the little toe inwards
Abductor minimi digiti.	The os cuboides and from the metatarſal bone of the little toe.	The outſide of the firſt bone of the little toe.	Expands the foot by carrying the little toe outwards.
Extenſor pollicis pedis longus.	The upper part of the fibula and interoſſeous ligament.	The upper part of the laſt bone of the great toe.	Extends the great toe, and raiſes it.
Extenſor pollicis pedis brevis.	The anterior inner part of the os calcis.	The upper part of the ſecond bone of the great toe.	Extends the ſecond joint.
Flexor longus pollicis pedis.	The ſuperior poſterior part of the fibula, near its head and from a part of the interoſſeous ligament.	Its tendon, paſſing under the malleolus internus, is inſerted into the baſis of the laſt bone of the toe.	Bends the great toe.
Flexor brevis.	The cuboid and external cuneiform bones.	The ſeſamoid bones of the ſecond joint of the toe.	Bends the ſecond joint of the toe.
Adductor pollicis.	The os calcis, from the cuneiform and cuboid bones, and from the metatarſal bone of the ſecond toe.	The ſecond bone of the great toe.	Bends the toe and draws it inwards.
Abductor pollicis.	The anterior inferior part of the os calcis, from a part of the os naviculare, and from the ſide of the firſt bone of the great toe.	The external ſeſamoid bone of the ſecond joint.	Bends the toe, and draws it outwards.
Tranſverſalis pedis.	The ſeſamoid bone of the great toe, and from the metatarſal bone that ſuſtains it.	Near the firſt joint of the leſſer toe, and its metatarſal bone.	Contracts the foot and brings the toes towards each other.
Deltoides.	The ſcapular extremity of the clavicle, from the ſpine of the ſcapula, and proceſſus acromion.	The outer middle part of the os brachii.	Raiſes the arm.
Supraſpinatus.	That part of the ſcapula which is above its ſpine,	The outer tubercle, near the head of the os brachii.	Raiſes the arm.
Infraſpinatus.	That part of the ſcapula which is below its ſpine,	The outer tubercle, near the head of the os brachii.	Raiſes the arm and moves it backwards.
Teres minor.	The fore part of the coſta ſcapulæ.	The outer tubercle, near the head of the os brachii.	Aſſiſts the former muſcle.
Teres major.	The inferior angle and coſta ſcapulæ.	Joins the tendon of the latiſſimus dorſi, and with it has a common inſertion.	Moves the arm downwards and backwards.
Coraco brachialis.	The point of the caracoid proceſs of the ſcapula.	The middle inner ſide of the os brachii.	Raiſes the arm.
Subſcapularis.	All the inner ſurface of the ſcapula.	The upper part of the os brachii.	Raiſes the arm, and brings it towards the ſide.
Biceps flexor cubiti.	Conſiſts of two heads; the longer ariſes from the neck of the ſcapular and its tendon paſſing through the capſular ligament of the humerus, plays over the head of the os brachii; is then lodged in a canal, made betwеen the two tubercles near the head of the bone.	Near the middle of the arm joins with the ſhorter head which ariſes from the coracoid proceſs of the ſcapula: inſerted into the tubercle of the radius near the joint, ſends off an aponeuroſis; which is extended over the muſcles on the inſide of the fore arm.	Is a flexor of the fore arm and a ſupinator of the hand.

NAME.	ORIGIN.	INSERTION.	USE.
Brachialis internus.	Ariſes from the middle anterior and inferior part of the os brachii.	Inſerted into the ulna, a little below the coronoid proceſs.	Bends the fore arm.
Biceps extenſor cubiti.	The long head ariſes from the inferior coſta ſcapulæ, the ſhorter, from the poſterior part of the os brachii, almoſt its whole length.	The external part of the ulna.	Extends the fore arm.
Brachialis externus.	All that part of the os brachii, which is below the teres-major.	The olecranon, in common with the biceps extenſor.	Extends the arm.
Angonæus.	Ariſes from the back part of the condyle of the os brachii.	Inſerted into the lateral part of the ulna, about an inch below the olecranon.	Aſſiſts the two former muſcles in the extenſion of the fore arm.
Palmaris longus.	The ſuperior part of that ridge leading to the inner condyle.	Has a long tendon, which is inſerted into the annular ligament of the carpus, and forms a part of the faſcia in the palm of the hand.	Bends the wriſt and tightens the faſcia.
Palmaris brevis.	The metacarpal bone ſuſtaining the little finger.	Its fibres paſſing tranſverſely are inſerted into the faſcia in the palm of the hand.	Tightens the faſcia.
Flexor carpi radialis.	The inner condyle of the os branchii, and from the upper part of the ulna.	The metacarpal bone that ſuſtains the fore finger.	Bends the carpus and hand.
Flexor carpi ulnaris.	With the former muſcle, with which its fibres are intermixed.	The os piſiforme.	Aſſiſts the former muſcle.
EXTENSOR CARPI RADIALIS, *ſeu bicornis.*	By two heads from the outer condyle of the os brachii.	Has two tendons of unequal length, the longer, inſerted into the baſis of the metacarpal bone ſuſtaining the index; the ſhorter, into the metacarpal bone ſuſtaining the middle finger.	Extends the carpus and carries the hand a little backwards.
Extenſor carpi ulinaris.	The outer condyle of the os brachii, from the outer part of the ancon, and from the outer edge of the ulna.	The upper part of the metacarpal bone ſuſtaining the little finger.	In its action aſſiſts the former muſcle.
FLEXOR SECUNDI INTERNODII DIGITORUM COMMUNIS, *ſeu perforatus.*	The inner condyle of the os brachii, from the coronoid proceſs of the ulna, and from the middle anterior part of the radius.	Divides into four tendons, paſſing under the annual ligament of the carpus; inſerted into the baſis of the ſecond bone of each finger.	Bends the ſecond joint of each finger.
FLEXOR TERTII INTERNODII DIGITORUM COMMUNIS, *ſeu perforans.*	All the upper outer part of the ulna, as it deſcends divides it into four tendons.	Theſe paſs under the annular ligament, and are inſerted into the baſis of the laſt bone of each finger; they paſs through, or perforate the tendons of the former muſcle.	Bends the laſt joint of each finger.
Lumbricales, four in number.	The upper tendons of the flexor digitorum.	By a broad tendon into the ſide of the baſis of the firſt bone of each finger.	The tendons being expanded on the back parts of the fingers, theſe muſcles bend the firſt joint and extend the others.
Extenſor digitorum communis	The external condyle of the os brachii, is blended with the ſupinator brevis, paſſing on the back part of the fore arm, is divided into five tendons.	Theſe are bound down by the annular ligament, two of them are inſerted into the little finger, and one into each of the other fingers.	Extends the fingers.
Interoſſei, ſix in number.	Are divided into external and internal, fill up the ſpaces between the metacarpal bones.	The ſides of the baſis of the firſt bones of the fingers.	Their tendons being ſpread out on the backs of the fingers, bend the firſt joint, and extend the other two.
EXTENSOR SECUNDI INTERNODII INDICIS PROPRIUS *vulgo indicator*	The middle poſterior part of the ulna.	The upper part of the baſis of the ſecond bone of the index.	Extends the fore finger.
Extenſor tertii internodii indicis.	The outer part of the metacarpal bone, ſuſtaining the fore finger.	Has two tendons, one inſerted into the ſide of the baſis of the firſt bone, the other ſpread out on the back part of the finger.	Extends the laſt joint of the fore finger.
Adductor indicis.	The ſide of the firſt bone of the thumb.	The baſes of the firſt bone of the finger next the thumb.	Bends the firſt joint of the finger, and brings it towards the thumb.
Extenſor minimi digitti.	The outer condyle of the os brachii, and from the back part of the ulna.	The laſt bone of the little finger.	Extends the little finger.
Extenſor tertii internodii minimi digiti.	The inner ſide of the bones of the carpus, and from the metacarpal bone ſuſtaining the little finger.	The upper part of the firſt bone of the little finger.	Extends the third joint of the little finger.
Abductor minimi digiti.	The inner ſide of the bones of the carpus.	The firſt bone of the little finger.	Carries the little finger outwards, and bends the firſt joint.
Flexor primi internodii minimi digiti.	The os unciforme, and from the fore part of the metacarpal bone ſuſtaining the little finger.	By two tendons, into the ſides of the baſis of the firſt bone of the little finger.	Bends the firſt joint, and hollows the hand.
Flexor tertii internodii pollicis.	The fore part of the radius, a little below its tubercle.	The baſis of the third bone of the thumb.	Bends the laſt joint of the thumb.
Flexor ſecundi internodii pollicis.	The trapezium principally at its upper part, blended with the following muſcle.	By two tendons, into the ſeſamoid bones, placed in the ſecond joint of the thumb.	Bends the ſecond join to the thumb.
Flexor primi internodii pollicis.	The annular ligament of the carpus, and from the trapezium.	The internal lateral part of the firſt bone of the thumb.	Bends the firſt joint.

NAME.	ORIGIN.	INSERTION.	USE.
Extenſor primi internodii pollicis.	The upper outer part of the ulna, from the interoſſeus ligament, and back part of the radius.	The back part of the firſt bone of the thumb.	Extends the firſt joint.
Extenſor ſecundi internoaii pollicis.	The middle back part of the radius and interoſſeus ligament.	The upper part of the baſis, of the ſecond bone of the thumb.	Extends the ſecond joint of the thumb.
Extenſor tertii internodii pollicis.	The middle back part of the ulna and interoſſeus ligament.	Its tendon, running in a ſulcus at the lower extremity of the radius, is inſerted into the laſt bone of the thumb.	Extends the laſt joint of the thumb.
Abductor pollicis.	The annular ligament of the carpus, from the trapezium and trapezoides.	The outer part of the ſecond bone of the thumb.	Moves the thumb outwards.
Adductor pollicis ad indicem.	The external lateral part of the metacarpal bone ſuſtaining the index.	The firſt joint of the thumb.	Brings the thumb towards the fore finger.
Adductor pollicis ad minimum digitum.	The metacarpal bone ſuſtaining the little finger.	The ſecond joint of the thumb, a little below the internal ſeſamoid bone.	Moves the thumb towards the little finger, and hollows the hand.
Pronator teres.	The internal condyle of the os braſſichii, from the anterior part of the ulna below the joint.	Paſſing obliquely, is inſerted into the middle outer part of the radius.	Turns the palm of the hand inwards and downwards.
Pronator quadratus.	The lower inner ſide of the ulna.	Paſſing tranſverſely, is inſerted into the inferior outer part of the lower extremity of the radius.	Aſſiſts the former muſcle in pronation of the hand.
Supinator longus.	The outer condyle of the os brachii, above the origin of the bicornis.	The external part of the lower extremity of the radius.	Turns the palm of the hand upwards
Supinator brevis.	The outer condyle of the os brachii, from the upper extremity of the ulna, and from the interoſſeous ligament.	The radius, a little below the inſertion of the biceps flexor.	Turns the palm of the hand upwards, and counteracts the pronators.

SECT. XII.

PHYSIOLOGY OF MUSCLES.

A Muſcle, in acting, either ſhortens itſelf or endeavours to do ſo. Muſcles, though in ſtrong action, may be ſometimes lengthened, *e. g.* If the force exerted by any muſcle, or ſet of muſcles, be counteracted by a force ſuperior to the relative power of the muſcle, that muſcle, though acting with its greateſt energy, will not be ſhortened. The actions of muſcles may differ, from a variety of circumſtances; 1ſt. from ſhape, viz. if a muſcle be oblong, it ſhortens itſelf in a ſtrait line, or its two extremities approach each other; but if a muſcle be circular, as a ſphincter, &c. then it puckers up the parts. 2dly, The action differs according to the courſe of the fibres; if the muſcle runs in a ſtrait line from one part to another, its contraction has the effect of bringing theſe two parts together; but if the muſcle or its tendon be reflected, the parts to which it is attached, will be moved at a diſtance from each other, as the trochlearis. 3dly, Different parts of the ſame muſcle can act independent of the whole, or of each other; this is particularly ſeen in the cucullaris, &c. 4thly, Some muſcles produce different effects, according to the different degrees of their action, and the different poſition of the limb; for inſtance, when the hand is in a ſtate of ſupination, the biceps flexor cubiti, is firſt a pronator of the hand, then a flexor of the fore-arm. 5thly, The effects of muſcles are different, according to the nature of the parts into which they are fixed; thoſe which paſs from bone to bone, by their contraction, move them towards each other; but thoſe which are inſerted into ſoft parts not only move them, but likewiſe alter the figure of the part. 6thly, The effects of muſcles are different, according to the number of them that act at the ſame time, *e. g.* If the flexors of the leg act alone, the limb will be bended, if the extenſors act they extend it, but if both extenſors and flexors act at the ſame time, the leg will neither be bended nor extended. If, whilſt a muſcle is in action, we examine it, the following phænomena may be obſerved: 1ſt, It grows tenſe, and endeavours to ſhorten itſelf in the direction of its fibres. 2dly, It grows harder in proportion to the energy with which it acts. 3dly, It becomes ſhorter if not overpowered by a ſuperior force: the degree of accurtation is in general about one third of its whole length; but in many muſcles of the body, particularly thoſe ſurrounding cavities, it is conſiderably more. 5thly, A muſcle in action is not increaſed in bulk, when we take all its parts together; it ſwells, indeed, at a particular part, but its whole bulk is neither increaſed nor diminiſhed. 6thly, Muſcles are not naturally in a ſtate of much tenſion; they have a tonic power, which enables them to adapt themſelves to the poſition in which they are placed, conſtantly keeping the fibres in a ſtraight line. The power which muſcles have, of contracting themſelves, is not owing merely to their arteries, veins or nerves, but is dependent on their longitudinal fibres, which in man and quadrupeds are red, and of different colours in other animals. Yet this power is in a particular manner dependent on the nervous ſyſtem, as appears from the following phænomena.

If a nerve going to a muſcle, be irritated, the muſcle is made to contract: this experiment has been frequently made on the diaphragm, by laying bare the phrenic nerve, and ſtripping it. Thence phyſiologiſts were led to ſuſpect, that muſcular fibres were hollow, and that contraction was produced by an influx of the nervous fluid into them. This idea was corrected, by obſerving that the experiment ſucceeds equally well, whether the nerves are ſtripped upwards or downwards, and that irritation of any kind will produce the ſame effect. If a nerve going to a muſcle be cut through, that muſcle loſes its power of contraction, though the effect is not immediate. Irritation of the brain produces contraction in the muſcles that receive their nerves from that part of it, ſimilar to irritation made on the nerves in any part of their paſſage from the brain to the muſcles they ſupply; hence ſpaſmodic contractions and convulſions are produced from irritation on the brain, *e. g.* compreſſion of the brain produces the ſame effects as the diviſion, or compreſſion of a nerve; therefore, if blood or matter be extravaſated, paralyſis will frequently enſue; all theſe phænomena ſhew ſo ſtrong a connection between the nervous and muſcular fibres, that ſome phyſiologiſts have ſuſpected, that muſcular fibres were only modifications of the nervous fibre. The nervous influence is not only neceſſary for muſcular action, but an influx of blood ſeems alſo requiſite; for if a muſcle be deprived of blood by the diviſion of its arteries, that muſcle not only ſuffers from want of nouriſhment, but alſo becomes paralytic; and this takes place in ſo ſhort a time, that ſome phyſiologiſts have ſuppoſed, that muſcular fibres were formed by a chain of hollow veſicles, and that muſcular contraction was produced by blood flowing into and diſtending them. Blood is not the efficient cauſe of contraction, though a *cauſa ſine qua non*. This power of contraction, is excited by ſtimuli, which are either corporeal, or mental. Muſcles differ from one another in being more or leſs influenced by the mind; the greater number of muſcles are obedient to the will, and the mind, when ſhe pleaſes, makes them contract; theſe we call voluntary muſcles; but ſome muſcles act involuntarily; ſome muſcles are of a mixed kind, as thoſe of reſpiration, being partly voluntary, and partly involuntary; at birth all muſcles are involuntary; the child moving the limbs in all directions, as excited by particular feelings. By degrees the mind acquires a power over moſt of the muſcles, ſo as to be able to direct their contraction; this power at firſt is very imperfect; as the power which the mind has over the muſcles is acquired, ſo it can be loſt, if diſcontinued; this ſeems to be partly the caſe in the limbs of thoſe who have been long bed-ridden. Muſcles, if long diſuſed, will degenerate into mere cellular membrane. The mind's power over the muſcles is not limited; nor is the force they are capable of exerting, ſo confined, as we might be led to ſuſpect. That the influence of the mind, and the power of action is increaſed by frequent uſe, is evinced, by obſerving, that we uſe the right hand with greater alacrity, than the left; and that the muſcles frequently uſed, act with greater energy than others, is proved by obſerving that the right arm of a fencing maſter, is ſtronger and larger than the left. The abſolute force of a muſcle, is the whole power it is capable of exerting, the relative force, the weight it is capable of raiſing, or diſplacing. Muſcles lying parallel to the bones, and being inſerted near to the centre of motion, loſe conſiderably of their abſolute force; if muſcles were inſerted into bones at right angles, they would have raiſed a weight as much heavier than that they are now capable of raiſing, as a right angle is greater than the angles they now make; but this diſadvantage is compenſated by the quickneſs of our motions. Muſcular contraction continues no longer than a ſtimulus is applied, therefore muſcles are alternately contracted and relaxed. In all voluntary motions, the mind applies the ſtimulus. Beſides the contraction which muſcles have on being irritated, they have a natural tendency to adapt themſelves to the ſpace into which they are placed; this is called the vis tonica. This power continues a ſhort time after life, and to this power, is owing: the contraction of hollow muſcles, when not diſtended mechanically.

PART IV.

ANGIOLOGY.

THE office of arteries, are to carry blood from the heart, to the diſtant parts of the body. The office of veins are to return that blood to the heart, when the purpoſes of the animal œconomy have been effected. The arteries, two in number, arteria pulmonalis, ariſing from the right ventricle of the heart, and aorta, ariſing from the left ventricle, theſe arteries, as they originate from the heart, decuſſate each other; every part of the body receives blood from the branches of the aorta, for the various purpoſes of nutrition, vivification and ſecretion. The branches of the aorta are diſtinguiſhed by particular names, deſcriptive of their ſituation and offices. The aorta, though originating from the left ventricle of the heart, is placed on the right of the ſpine: from the left ventricle, it aſcends as high as the joint between the firſt and ſecond bones of the ſternum; this part called ſinus aortæ; then bending to the left of the ſpine, it forms an arch called curvature of the aorta; between the beginning of the aorta and the left ventricle, are three valves, called valvulæ ſemilunares, theſe prevent the return of blood from the aorta into the ventricle. The arteries coming from the aorta, ariſe in the following order:

Arteriæ coronariæ, reflected from the aorta; their orifices being covered by the valvulæ ſemilunares, are diſtributed to the heart.

Arteriæ thymicæ, ariſe from the ſinus aortæ, large in the fœtus, ſupplying the thymus gland with blood. In the adult, ſmall, and principally diſtributed to the anterior mediaſtinal ſpace.

From the curvature of the aorta, here ariſes three veſſels; the firſt, being anterior, is the common trunk of the carotid and ſubclavian on the right ſide; the ſecond, the left carotid; and the third, left ſubclavian.

The carotid artery aſcends on the fore part of the neck, on the ſide of the trachea arteria, as high as the angle of the lower jaw, without giving off any branch: here, it divides into two trunks, called external and internal carotid. The external, is divided into the five following branches:

1. Thyroidæa ſuperior, or ſuperior guttural, ſupplies the ſuperior part of the thyroid gland.

2. Sublingualis, paſſing under the mylo hyoidæus, is diſtributed to the ſurface of the tongue, to the muſcles that move it, and to ſome muſcles of the pharynx.

3. Facialis, bends under the jaw and ſends off a branch to the chin, called genial; thence, paſſing over the baſis of the jaw, near the anterior edge of the maſſiter, aſcends on the ſide of the cheek, ſends a branch to the lower lip, called inferior labial, one to the upper lip, called the ſuperior labial, a branch to the noſe, called naſal, and ſome ſmall branches to the muſcles and ſkin of the face. The remaining part of the trunk, paſſing between the noſe and cheek, ſends a branch through the foramen orbitale externum inferius, then paſſing to the inner canthus of the eye, is called angular artery, this ſends a branch into the orbit, which anaſtamoſes with a branch from the arteria optica. The remaining branches are diſtributed to the muſcles and ſkin of the forehead.

4. Occipitalis paſſing behind the maſtoidæus and ſplenius, ſends branches to the muſcles and ſkin on the back part of the head, theſe anaſtamoſe with the branches of the temporal artery.

5. Superior maxillary paſſing within the proceſs of the lower jaw, ſends the ſuperficial temporal artery, which paſſing through the parotid gland, ſupplies it with blood, then aſcending on the ſide of the head, and giving off branches to the adjacent parts, divides into three branches, the middle one paſſing immediately upwards, is diſtributed to the ſuperior part of the ſcalp, and communicates with its fellow on the oppoſite ſide, the poſterior paſſing obliquely backwards, communicates with the occipitalis, the anterior running obliquely forwards, communicates with the branches of the facial artery. The trunk lying within the proceſs of the lower jaw, gives off branches to the pterigoid muſcles, the deep ſeated temporal, ſupplying the temporal muſcle with blood, ſends branches to Schnider's membrane, to the antrum highmorianum and an artery, which paſſing through the foramen ſpinoſum, is diſtributed to the dura mater.

Internal carotid or cerebralis paſſing through the ſpiral canal in the petrous portion of the temporal bone, runs on the ſide of the ſella turcica, ſends off a branch, called arteria optica, which paſſing through the foramen opticum, is diſtributed to the eye-ball and its appendages, other branches from the internal carotids, anaſtamoſe, with branches from the baſilary artery, and form a circle of communication round the ſella turcica, called circus arterioſus Williſii; the branches of the internal carotids are ſpread out on the pia mater, and ſupply the brain with blood.
